SELECT COMMITTEE ON ASTRONAUTICS AND SPACE EXPLORATION

(Created by H Res 496, March 5, 1958, 85th Cong)

JOHN W McCORMACK, Massachusetts, *Chairman* [1]

OVERTON BROOKS, Louisiana	JOSEPH W MARTIN, JR , Massachusetts
BROOKS HAYS, Arkansas	LESLIE C ARENDS, Illinois
LEO W. O'BRIEN, New York	GORDON L McDONOUGH, California
LEE METCALF, Montana	JAMES G FULTON, Pennsylvania
WILLIAM H NATCHER, Kentucky	KENNETH B KEATING, New York
B. F SISK, California	GERALD R FORD, JR , Michigan

GEORGE J FELDMAN, *Chief Counsel and Director*
DR CHARLES S SHELDON II, *Assistant Director*
SPENCER M. BERESFORD, *Special Counsel*
RICHARD P HINES, *Committee Clerk*
RAYMOND WILCOVE, *Director of Research*
HARNEY S. BOGAN, JR , *Assistant Counsel*
PHILIP B. YEAGER, *Special Consultant*

[1] The permanent assignments of the chairman and the other members of the above committee will be found on p VIII.

CONTENTS

PERMANENT ASSIGNMENTS OF MEMBERS OF THE SELECT COMMITTEE ON ASTRONAUTICS AND SPACE EXPLORATION

JOHN W. McCORMACK, Chairman	Majority leader. Committee on Government Operations.
OVERTON BROOKS	Committee on Armed Services. Committee on Government Operations. Joint Committee on Smithsonian Institution Museum of History and Technology Building.
BROOKS HAYS	Committee on Foreign Affairs.
LEO W. O'BRIEN	Committee on Interior and Insular Affairs Committee on Interstate and Foreign Commerce
LEE METCALF	Committee on Education and Labor. Committee on Interior and Insular Affairs
WILLIAM H. NATCHER	Committee on Appropriations.
B. F SISK	Committee on Interior and Insular Affairs. Committee on Veterans' Affairs.
JOSEPH W. MARTIN, Jr	Minority floor leader.
LESLIE C. ARENDS	Minority whip. Committee on Armed Services.
GORDON L McDONOUGH	Committee on Banking and Currency. Joint Committee on Defense Production.
JAMES G FULTON	Committee on Foreign Affairs.
KENNETH B. KEATING	Committee on the Judiciary. Joint Committee on Immigration and Nationality Policy.
GERALD R. FORD	Committee on Appropriations.

ASTRONAUTICS AND SPACE EXPLORATION

TUESDAY, APRIL 15, 1958

HOUSE OF REPRESENTATIVES,
SELECT COMMITTEE ON ASTRONAUTICS
AND SPACE EXPLORATION,
Washington, D. C.

The committee met at 10 a. m., pursuant to notice, in the caucus room, Old House Office Building, Hon. John W. McCormack (chairman) presiding.

Present: Representatives McCormack, Brooks, Hays, O'Brien, Natcher, Sisk, Arends, McDonough, Fulton, Keating, and Ford.

Present Also: George J. Feldman, Director and chief counsel

The CHAIRMAN. The committee will be in order.

This is the first public hearing of our committee. Its purpose has been set forth by the House:

> To conduct a thorough and complete study and investigation with respect to all aspects and problems relating to the exploration of outer space and the control, development, and use of astronautical resources, personnel, equipment, and facilities.

We plan to conduct these hearings openly. The scope and detail of their disclosures will be limited only by actual questions of national security. To work in any other way would do a disservice to the country. The problems that face the Congress and the Nation in matters of outer space development are so immense and so critical that they must have the help of an informed public opinion.

In space exploration, and the scientific breakthrough it implies, we are beginning an era of discovery literally as far-reaching as the discovery of our own continent. It is necessary that each broad step in this discovery be made with the American people being as fully informed as possible.

An urgent task of this committee and of the Congress is to enact effective legislation to meet this problem. President Eisenhower has sent a message to the Congress in which he summarized many of the problems and functions that this new organization would handle. He has proposed a National Aeronautics and Space Agency for this task and I have introduced his proposal as H. R. 11881. I am sure the committee will give full thought to this proposal in working out a bill to serve best the purposes which the President set forth.

We cannot overstress the importance of immediate action in the field of space exploration. We must enact legislation for the immediate future and must also lay the groundwork for a long-term effort of exploration and scientific development.

The immediate problem is obvious. We see another nation of great potentiality, militant and competitive, which has already made

the first advances in the mastery of outer space. We cannot stand by and watch this nation make that mastery complete. As Lt. Gen. James M. Gavin, the Army's recently retired Chief of Research put it:

> If they—

that is, the Russians—

> surpass us in technology in the years ahead, there is little doubt who will determine the future of the world

As we make this emergency effort, we must remember it is only the first step in a continuing program of outer-space development, a development which will open new horizons with each unfolding discovery. When the atomic bomb was first exploded, even the men who created it had little idea of the tremendous advances in peacetime development which nuclear power would bring. The use of radioactive isotopes alone has saved American industry millions of dollars a year. In atomic power, the world is finding a great new source of energy. In medicine its value becomes increasingly clear. Thus, despite the specter of nuclear warfare, we begin to see that this new device of science can be made a great force for peace.

With the exploration of outer space, we run into the same huge problems and the same tremendous potential. Our scientists now know the value of space exploration for predicting the weather and, in the end, controlling it. It is difficult to imagine the great and beneficent revolution this would make in farming, in industry, and our daily lives. We have heard also of the value to communications and to our transportation systems that may arise out of this new medium.

What else space holds for us is beyond the threshhold. What we will learn from the moon, and probably the other planets, no man can rightly say. On the basis of what we already know, we can predict that the advances will be literally beyond our present understanding They are giving this country a new frontier. I need not remind you how our American democracy grew great on the older, limited frontiers of the past. The worlds of outer space are the greatest challenge to dynamic thought and deed that our pioneer spirit has ever received.

The stakes are tremendous.

We have many questions before us. Shall the new Agency be controlled by military men or by civilians? Can a civilian organization look after military needs as well? How big—and how limited—will be the new Agency's jurisdiction? Will it act on space problems alone?

Through all these considerations we must also continually balance two things: the immediate emergency needs—the long-range possibilities and their cost. We must also look at the other dark side of the coin. What would Soviet ascendancy in this field mean, to our safety, if not our existence as a Nation?

These are some of the questions which we hope to clarify during our hearings. In keeping with the urgency of this investigation, we are calling no witness who is not absolutely essential to it. Since the first advances in space exploration were made under the direction of the military, our witnesses will include some of those who have been most intimately concerned with the present space plans. Other witnesses will represent broader civilian and scientific aspects of outer space and astronautics.

Without objection, the message of President Eisenhower will be made a part of the record.

Also, without objection, the bill as submitted by the Bureau of the Budget and introduced by myself, will be made a part of the record.

I understand maybe 1 or 2 other Members may have introduced the same bill. If so, we will incorporate that fact into the record.

Without objection, a memorandum prepared for me on March 7, 1958, by Mrs. Eilene Galloway, National Defense analyst of the Foreign Affairs Division of the Legislative Reference Service of the Library of Congress will be made a part of the record.

It is a very interesting memorandum, copies of which, I understand, have been sent to each member of the committee.

Is that correct, Mr. Feldman?

Mr. FELDMAN. Yes, it is.

(The material referred to follows:)

[H. Doc No 365, 85th Cong, 2d sess]

MESSAGE FROM THE PRESIDENT OF THE UNITED STATES RELATIVE TO SPACE SCIENCE AND EXPLORATION

To the Congress of the United States:

Recent developments in long-range rockets for military purposes have for the first time provided man with new machinery so powerful that it can put satellites into orbit, and eventually provide the means for space exploration. The United States of America and the Union of Soviet Socialist Republics have already successfully placed in orbit a number of earth satellites. In fact, it is now within the means of any technologically advanced nation to embark upon practicable programs for exploring outer space The early enactment of appropriate legislation will help assure that the United States takes full advantage of the knowledge of its scientists, the skill of its engineers and technicians, and the resourcefulness of its industry in meeting the challenges of the space age.

During the past several months my Special Assistant for Science and Technology and the President's Science Advisory Committee, of which he is the Chairman, have been conducting a study of the purposes to be served by a national space program, of the types of projects which will be involved, and of the problems of organizing for space science functions. In a statement which I released on March 26, 1958, the Science Advisory Committee has listed four factors which in its judgment give urgency and inevitability to advancement in space technology. These factors are (1) the compelling urge of man to explore the unknown; (2) the need to assure that full advantage is taken of the military potential of space; (3) the effect on national prestige of accomplishment in space science and exploration; and (4) the opportunities for scientific observation and experimentation which will add to our knowledge of the earth, the solar system, and the universe.

These factors have such a direct bearing on the future progress as well as on the security of our Nation that an imaginative and well-conceived space program must be given high priority and a sound organization provided to carry it out. Such a program and the organization which I recommend should contribute to (1) the expansion of human knowledge of outer space and the use of space technology for scientific inquiry, (2) the improvement of the usefulness and efficiency of aircraft, (3) the development of vehicles capable of carrying instruments, equipment, and living organisms into space, (4) the preservation of the role of the United States as a leader in aeronautical and space science and technology, (5) the making available of discoveries of military value to agencies directly concerned with national security, (6) the promotion of cooperation with other nations in space science and technology, and (7) assuring the most effective utilization of the scientific and engineering resources of the United States and the avoidance of duplication of facilities and equipment.

I recommend that aeronautical and space science activities sponsored by the United States be conducted under the direction of a civilian agency, except for those projects primarily associated with military requirements. I have reached this conclusion because space exploration holds promise of adding importantly to our knowledge of the earth, the solar system, and the universe, and because it

is of great importance to have the fullest cooperation of the scientific community at home and abroad in moving forward in the fields of space science and technology. Moreover, a civilian setting for the administration of space function will emphasize the concern of our Nation that outer space be devoted to peaceful and scientific purposes

I am, therefore, recommending that the responsibility for administering the civilian space science and exploration program be lodged in a new National Aeronautics and Space Agency, into which the National Advisory Committee for Aeronautics would be absorbed. Hence, in addition to directing the Nation's civilian space program, the new Agency would continue to perform the important aeronautical research functions presently carried on by the National Advisory Committee for Aeronautics The new Agency would be headed by a Director appointed by the President by and with the advice and consent of the Senate.

In order to assist the President and the Director of the National Aeronautics and Space Agency, I recommend that a National Aeronautics and Space Board, appointed by the President, be created. Several of the members of the Board should be from the Government agencies with the most direct interest in aeronautics, space science, and space technology To assure that military factors are considered by the Board, at least one member should be appointed from the Department of Defense. Members appointed from outside the Government should be eminent in science, engineering, technology, education, or public affairs, and be selected solely because they have established records of distinguished achievement.

The National Aeronautics and Space Agency should be given that authority which it will need to administer successfully the new programs under conditions that cannot now be fully foreseen

In order that the Agency may attract and retain the services of scientists and technicians which it must have to carry out its responsibilities with full effectiveness, it should have the authority, subject to regulations prescribed by the President, to fix the compensation of its employees at rates reasonably competitive with those paid by other employers for comparable work without regard to the provisions of existing classification laws

The Agency should have the power to conduct research projects in its own facilities or by contract with other qualified organizations It will thus be free to enlist the skills and resources required for the space program wherever they may be found, and to do so under the arrangements most satisfactory to all concerned Provision should also be made for continuing and further enhancing the close and effective cooperation with the military departments which has characterized the work of the National Advisory Committee for Aeronautics. Under such cooperative arrangements it is expected that the National Aeronautics and Space Agency will perform research required in the furtherance of strictly military aeronautics and space objectives, just as the National Advisory Committee for Aeronautics now carries on important research work for the military services in aerodynamics, propulsion, materials and other fields important to the development of military aircraft and missiles

The National Advisory Committee for Aeronautics is already engaged in research directly related to flight outside the earth's atmosphere and has research facilities adapted to work in space science Upon the enactment of legislation carrying out my recommendations, all of the resources of the National Advisory Committee for Aeronautics would immediately come under the direction of the new Agency. The Department of Defense and its contractors, as well as other agencies, have active programs which should be considered for administration by the National Aeronautics and Space Agency I recommend that this fact be taken into account and provision made for the transfer to the Agency of such functions, activities, and facilities of other departments and agencies as may be found to be appropriate for administration by the new Agency, subject to the concurrence of the heads of the affected agencies and with the approval of the President.

The Director of the Bureau of the Budget is transmitting to the Congress draft legislation to establish the National Aeronautics and Space Agency and to authorize research into the problems of flight within and outside the earth's atmosphere. I urge that the Congress give prompt consideration to the draft legislation and that it be enacted at the earliest possible date

Pending enactment of legislation, it is essential that necessary work relating to space programs be continued without loss of momentum. For this reason, I have approved, as part of an interim program of space technology and exploration, the launching of a number of unmanned space vehicles under the direction of the

Advanced Research Projects Agency of the Department of Defense. The projects which I have approved include both scientific earth satellites and programs to explore space. In taking this interim action, I directed the Department of Defense to coordinate these projects with the National Advisory Committee for Aeronautics, the National Science Foundation, and the National Academy of Sciences. I also indicated that when a civilian space agency is created, these projects would be reviewed to determine which should continue under the direction of the Department of Defense and which should be placed under the new Agency.

It is also important that measures be taken to assure the prompt and orderly implementation of the proposed aeronautics and space legislation when enacted I am requesting the Department of Defense and the National Advisory Committee for Aeronautics to review pertinent programs of the Department and to recommend to me those which should be placed under the direction of the new Agency I have also asked that they prepare an operating plan to assure support of the new Agency by organizations, facilities, and other resources of the Department of Defense, either by cooperative arrangements or by transfer to the new Agency.

It is contemplated that the Department of Defense will continue to be responsible for space activities peculiar to or primarily associated with military weapons system or military operations Responsibility for other programs is to be assumed by the new Agency In this connection, I commend to the attention of the Congress the comments of my Science Advisory Committee, in its statement of March 26, 1958, on the military applications of space technology.

I am also asking the National Advisory Committee for Aeronautics to begin immediate preparation of such detailed plans as may be required to prepare for the assumption by the National Aeronautics and Space Agency of the responsibilities contemplated for it. Those plans are to set forth the specific new space programs to be initiated and are to describe the internal organization, management structure, staff, facilities, and funds which will be required. The National Advisory Committee for Aeronautics is to discuss with the National Science Foundation and the National Academy of Sciences the matter of participation by the scientific community in determining the scientific objectives of our space programs. The best scientific judgment available should be utilized. Matters related to dissemination of the data collected should also be considered

I have also instructed the National Advisory Committee for Aeronautics to assume the responsibility for preparing and presenting to the appropriate committees of the Congress a full explanation of the proposed legislation and its objectives

The vigorous program contemplated will depend not only on adequate legislative authority but also on adequate financial support. I shall shortly submit to the Congress an amendment to the fiscal year 1959 budget to provide funds that will be needed by the new Agency in its first year of operation.

DWIGHT D. EISENHOWER.

THE WHITE HOUSE,
April 2, 1958

THE PROBLEMS OF CONGRESS IN FORMULATING OUTER-SPACE LEGISLATION

Prepared at the request of, and according to instructions from, the Honorable John W. McCormack, Chairman, Select Committee on Astronautics and Space Exploration, House of Representatives, by Mrs Eilene Galloway, National Defense Analyst, Foreign Affairs Division, the Library of Congress, March 7, 1958

I. THE NEW FRONTIER

The successful launching of an earth satellite by the Russians on October 4, shortly followed by a second and much heavier "sputnik" on November 3, 1957, was a dramatic announcement to the world of scientific progress which opened up new realms for man's exploration of outer space While the United States was caught unawares by this evidence of Soviet mastery of science and technology, it was not far behind in sending its Explorer into orbit on January 31, 1958.

The repercussions of this situation upon the Congress can only be understood in the context of the extreme complexity of outer-space exploration and control. A basic knowledge of science and technology is required in order to determine the relationship of outer-space development to national and international law, national defense, foreign relations, education, communications, and navigation,

weather control, medical research, and the organization and administration of the Government for handling such a combination of subjects. The scientific facts which can be established at the present time, supplemented by our constant increase in knowledge and experience, are essential to the determination of what is feasible and what is impracticable; of those aspects of outer space which can be adequately covered by a national law and those which will require international cooperative arrangements.

From the outset it was apparent that a breakdown of the total subject of outer space into its component parts resulted in specialized topics which cut across the jurisdictional lines of many committees of the Congress. It was not possible to refer bills concerned with outer-space development to one authorizing committee and one appropriations subcommittee for determination. A few hypothetical examples may serve to illustrate both the complexity of the subject and the problem of committee jurisdiction

The Committees on Agriculture would be interested in new methods of weather control which might be accomplished from outer space. The Committees on Armed Services would expect to consider satellites and their connection with long-range ballistic missiles, particularly propulsion systems and problems of reentry into the atmosphere. The House Education and Labor Committee and the Senate Committee on Labor and Public Welfare would have a vital concern with the education of future scientists, laboratory facilities, and grants-in-aid. The Committee son Foreign Affairs and Foreign Relations would expect to consider proposals for the international control of space, international space law and its effects upon national sovereignty and existing treaties and agreements. The Government Operations Committees might wish to study background information which bore on the various problems of their subcommittees The House Interstate and Foreign Commerce Committee has already issued a report on the International Geophysical Year as it pertains to the Arctic and Antarctica, and both House and Senate committes could be expected to have a continuing interest in outer-space projects which affected their jurisdiction over civil aviation, communications, weather, and science. Conceivably the Public Works Committees might consider nonmilitary installations, and the Post Office and Civil Service Committees would be interested in proposals for mail delivery by rockets. A number of subcommittees of the Appropriations Committees would receive authorizations, possibly creating the problem of coordination by the full committees. The Joint Committee on Atomic Energy would be concerned with warheads for outer-space weapons, propulsion devices, the reentry problem, arrangements for sharing information with our allies, and any peaceful uses which required atomic energy as a fuel.

The fact that many committees would have a vital concern with various aspects of outer space is only part of the problem. As such, it raises the question of whether we could expect the sum of the parts to result in a total national effort without some form of congressional coordination. But the greatest complication arises when we consider that one segment of the total outer-space problem may be of primary interest to several committees simultaneously. For example, weather control could come before the Congress in the form of a bill which could be referred to the Committees on Agriculture, Armed Services, Foreign Affairs, Foreign Relations, Interstate and Foreign Commerce; and if the proposed type of weather control involved the use of atomic energy, the matter could also come within the jurisdiction of the Joint Committee on Atomic Energy.

II. HOW CONGRESS MOVED OUT ON THIS FRONTIER

On November 27, 1957, the Preparedness Investigating Subcommittee of the Senate Armed Services Committee began its inquiry into satellite and missile programs. Concluding its first series of hearings on January 23, 1958, the chairman, Senator Lyndon B. Johnson, listed 17 principal areas recommended for decisive action in strengthening our national defense Hearings concerned with outer space and related problems were also held by both Appropriations' Committees, the House Armed Services Committee, and the Special Subcommittee on Outer Space Propulsion of the Joint Committee on Atomic Energy

On February 6, 1958, the Senate established a Special Committee on Space and Astronautics which was directed to make a thorough study of "all aspects and problems relating to the exploration of outer space and the control, development, and use of astronautical resources, personnel, equipment, and facilities." The committee report to the Senate is due by June 1, 1958 "or the earliest practical date thereafter, but not later than January 31, 1959, by bill or otherwise. * * *" Senator Lyndon B. Johnson is chairman of the 13-member committee.

On March 5, 1958, the House of Representatives established the Select Committee on Astronautics and Space Exploration composed of 13 members with Hon. John W. McCormack as chairman. This committee is "authorized and directed to conduct a thorough and complete study and investigation with respect to all aspects and problems relating to the exploration of outer space and the control, development, and use of astronautical resources, personnel, equipment, and facilities." The committee report to the House is due by June 1, 1958, or earlier, but not later than January 3, 1959.

To cover the situation in the meantime, the Congress passed Public Law 85-325 which provides in section 7 that—

"The Secretary of Defense or his designee is authorized to engage in such advanced projects essential to the Defense Department's responsibilities in the field of basic and applied research and development which pertain to weapons systems and military requirements as the Secretary of Defense may determine after consultation with the Joint Chiefs of Staff, and for a period of 1 year from the effective date of this act, the Secretary of Defense or his designee is further authorized to engage in such advanced space projects as may be designated by the President."

In passing the supplemental defense appropriation for fiscal 1958, the Congress approved $10 million in transfer authority for advanced research, and on February 7, 1958, the Secretary of Defense established the Advanced Research Project Agency and named Roy W. Johnson as Director (Public Law 85-322) These arrangements make it possible for outer space projects, both military and nonmilitary, to proceed during the time it takes to formulate permanent legislation for the organization of the executive branch and of the Congress in the handling of outer space problems.

Meanwhile, the President has asked that his scientific adviser, Dr. James W. Killian, Jr., make a study of the kind of organization needed for the future development of outer space.

III. COMPARISON AND CONTRAST OF OUTER SPACE AND ATOMIC ENERGY AS A LEGISLATIVE PROBLEM

The task of the House and Senate committees in formulating outer space legislation has been compared to that of the McMahon committee which held hearings and drew up the original Atomic Energy Act of 1946 An analysis of the similarities and differences of these two subjects may provide guidance in our approach to outer space at the present time.

Atomic energy and outer space are alike in opening new frontiers which are indissolubly linked with the question of war and peace. They combine the possibility of peaceful uses for the benefit of man and of military uses which can destroy civilization. Both are national and international in their scope They involve the relation of science and government, the issue of civilian or military control, and problems of organization for the executive branch and the Congress. If only their similarities are considered, the legislative task would appear to be the easy one of following the pattern of our present atomic energy legislation.

When the differences between atomic energy and outer space are analyzed, however, it becomes apparent that the present assignment is far more complicated than that which confronted the Congress in 1946. As a source of great power derived from a mineral, uranium, atomic energy can be easily defined and its source can be controlled, its use licensed or prohibited, and there is no legal difficulty in devising penalties against its misuse in a national law. Outer space, on the other hand, is comparable to an unexplored geographic area which is unmapped as far as legal definitions are concerned. We cannot control, license, or prohibit the use of outer space by other nations, and thus there are large areas of the subject which are not amenable to a Federal law. It follows, therefore, that one of the unique tasks of the committee will be to determine the line between those aspects of outer space which can be governed by the United States and those which will require international cooperation. In order to do this it will be necessary first to assemble the scientific facts and to arrive at definitions of outer space which will be acceptable not only within the United States but within the international community of nations Unless this is done, there is the like hood that our national law may contain provisions which might prevent us at some later time from participating in some form of international control.

The line between the peaceful and military uses of outer space is much more difficult to draw than is the case with atomic energy. There are peaceful uses of atomic energy which obviously have no military application, e. g., radioisotope

research in various forms, particularly cancer research. Practically every peaceful use of outer space appears to have a military application. For example, the Military Establishment is concerned with weather control, all forms of communication, reconnaissance satellites for mapping; and, even medical research on weightlessness has implications for satellite weapons. Thus it is possible for a nation to send up a peaceful satellite for scientific purposes and to be accused—justly or unjustly—of engaging in this activity for military purposes. If a study of the scientific facts of outer space leads to the conclusion that most if not all exploration yields knowledge which can be used for military purposes by any nation engaged in such activity, then civilian control may be an answer to only part of the total problem. We can establish civilian control within the United States, but if it turns out that peaceful uses cannot be scientifically separated from military implications, then how are we to regulate the international civilian-military situation? Here, again, it will be necessary to ask the scientists precisely how outer space can be controlled for the benefit of mankind and what projects can be devised which will have worldwide acceptance as being peaceful in their nature.

At least one difference between atomic energy and outer space is an advantage rather than a complication. The first use of atomic energy was in the form of bombs used during a war, the first use of earth satellites has been for peaceful purposes. Satellites have not progressed to the point where they are weapons even though their launching devices may be the same as those used for IRBM's and ICBM's. There are 64 nations cooperating in the studies inaugurated by the International Geophysical Year, and since this worldwide effort was started by the scientists themselves, there is room for hope that at least some parts of the IGY program can be continued into the future. Perhaps the scientists and the political scientists will be able to make proposals which will provide for the coordination of national legislation with international arrangements. If some effort is not made along this line, there is danger that this gain in international cooperation may be dissipated.

The existing situation and the time element with which the House and Senate Committees on outer space have to contend is more difficult than that faced by the committee which investigated atomic energy in 1946. At that time the war was at an end, the United States had a monopoly on atomic energy and it was possible to take time to formulate legislation without feeling that meanwhile the situation might get out of hand. No other nation was then engaged in atomic energy development as advanced as that of the present satellite program of the Soviet Union. Atomic energy information could be classified whereas data on satellites is being shared by agreement among the nations participating in the International Geophysical Year.

Furthermore, the atomic energy program within the United States was easier to deal with in 1946 than is the case with outer space in 1958. Atomic energy had been developed by 1 military departmant and was headed by 1 man, whereas outer-space programs are now actively under in 3 military departments where they have been subjected to a plethora of committees. We now have one director for guided missiles and another for antimissile missiles and satellites. The personnel and facilities for outer-space projects are widely dispersed, and the first nonmilitary development of earth satellites has been the responsibility of military departments. If the people who know how to produce outer-space vehicles are not located in the military departments, they are largely employed by business firms or universities operating under contracts from the Army, the Navy, or the Air Force. It will be a difficult legislative task to devise a law for the effective organization and administration of these far-flung operations in which the military and non-military are so closely associated.

IV. LEGISLATIVE PROPOSALS AND ISSUES

Several bills providing for outer-space development have already been introduced in the Congress, and these combined with the present arrangement whereby both military and nonmilitary programs are the responsibility of the Department of Defense, provide 5 alternative methods for the organization of the executive branch and at least 3 for the Congress. Additional proposals may be made in the future, but at the present time it is possible to see the large outlines of emerging patterns.

A. Alternative proposals for organization of the executive branch

1. *Development of outer space by the Department of Defense*.—Thus far the United States satellite programs have been conducted within the Department of Defense

and will continue there until the Congress makes different arrangements than those now established for the Advanced Research Projects Agency The fact that this Agency was given responsibility only until February 12, 1959, for engaging in nonmilitary advanced space projects designated by the President suggests that the Congress considered this to be a temporary arrangement to take care of the situation pending further study of the matter The personnel, resources, and facilities for outer-space projects are now located within the Department of Defense, and within the Army, the Navy, and the Air Force, there are teams of people who are already organized to achieve certain objectives For this reason it may be expected that the advantages and disadvantages of removing outer space from the Pentagon will be strongly presented

Since the President has already expressed his approval of civilian control of outer-space programs for scientific purposes, and since the Congress has presumably left nonmilitary projects in the Pentagon as a temporary expedient, it seems likely that the main concern will be with the following questions

(1) Upon the basis of what scientific facts can a line be drawn between military and nonmilitary outer-space projects?

(2) What effective arrangements can be made by a civilian agency for meeting the military requirements of the Department of Defense?

(3) Will the same launching devices be used for military and nonmilitary satellites or will a new civilian agency develop its own equipment?

(4) How shall we divide the limited personnel and existing facilities for outer-space development between the Pentagon and a new civilian agency?

2. *Development of outer space by the Atomic Energy Commission.*—This proposal would amend the Atomic Energy Act of 1954 by adding a Division of Outer Space Development to the Atomic Energy Commission Those who favor this proposal point out that the AEC has been operating successfully for some years in a scientific field which combines peaceful and military projects It has been able to meet the requirements of the Department of Defense and to advance the peacetime uses of atomic energy in a variety of ways On the other hand, a question has been raised with regard to the adequacy of the Commission's personnel and facilities for developing outer space Several questions might be explored in order to estimate the probable repercussions of placing outer-space development in the Atomic Energy Commission

(1) Will it not be necessary to arrive at accepted definitions for outer space before placing the subject in a law which legally defines atomic energy? Will all the provisions of the Atomic Energy Act of 1954 be applicable to outer space, and if not, should a determination be made in advance of all the changes in the law which would be necessary for the legal accommodation of outer space?

(2) If it is decided to remove purely scientific outer-space projects from the administration of the Department of Defense, would the transfer of personnel and facilities to the Atomic Energy Commission be any different from their transfer to some other type of civilian agency?

(3) If outer space is not to be administered by the Atomic Energy Commission, how will its work on related nuclear devices be effectively coordinated with the outer-space projects of a new civilian agency?

(4) If outer space is to be administered by the Atomic Energy Commission, would it be desirable to change the name of the Commission to correspond to its new terms of reference?

3 *Development of outer space by a new Commission.*—This proposal would establish a Commission on Outer Space which would be patterned essentially along the lines of the present Atomic Energy Commission. The possible effects of this proposal may be analyzed by raising the following questions:

(1) How would the relationship between the Commission on Outer Space and the present Atomic Energy Commission be worked out?

(2) Is it possible that the two Commissions might duplicate work on launching devices and propellents for long range missiles and satellites?

(3) Would the Department of Defense encounter any administrative difficulties in obtaining nuclear warheads from the Atomic Energy Commission and outer-space vehicles for the delivery of warheads from the Outer Space Commission?

(4) Would it be practicable and scientifically feasible for the Commission on Outer Space to be primarily concerned with peaceful uses while the Department of Defense retained control over the military uses of outer space?

(5) Since outer-space development is closely connected with the conduct of our foreign relations in such a manner as to prevent war, what would be the relationship between the new Commission and the Department of State? (This same question might be asked with regard to each of the five alternative proposals)

25973—58——2

4. *Coordination of the outer-space program by the National Advisory Committee for Aeronautics working with the National Academy of Sciences and the National Science Foundation.*—Under this proposal or some variation of it, planning and priorities would be undertaken by the National Academy of Sciences, appropriations and construction would be the concern of the National Science Foundation, while the NACA would coordinate nonmilitary space projects and work in a liaison capacity with the Advanced Research Projects Agency in the Department of Defense.

Those who advocate outer-space development by the NACA emphasize its contributions to aeronautics during the past 4 decades, the high quality of its leadership, and its production of new research tools, e. g., multistage research rockets and the transonic wind tunnel. Debate on the subject has not shaped up to the point where any disadvantages have been brought to light, and the determination of what would be likely to happen if outer space were given to the NACA would seem to depend upon the evaluation of testimony from expert witnesses. Some of the questions which might be asked are as follows:

(1) Should the total responsibility for outer-space development be located in an agency which is primarily scientific and technical?

(2) How would the executive branch of the Government be organized to deal with outer-space developments which affected the conduct of foreign policy? What would be the relationship between the NACA, the ARPA, the President's scientific adviser, and the Secretary of State?

(3) What agency or official would coordinate our national outer-space effort with proposals for international cooperation? Is it contemplated that the National Security Council will function in this area?

(4) What agency will handle questions of international space law?

(5) Is NACA strongly favored by the scientists as an agency offering the best atmosphere for a working relationship between science and government?

5 *Development of outer space within a Department of Science*—Proposals have been advanced for a Department of Science at the Cabinet level, and if this step were taken, outer space would be one of many subjects which would be referred to the new organization Since this proposal would involve the transfer of scientific activities from practically every department of the Government, its evaluation would necessarily include far more factors than those involved in outer space. An appraisal of how outer-space development might be expected to progress in a Department of Science would require expert testimony on all of the questions which have been listed in this paper.

B. Alternative proposals for organization of the Congress

Proposals have been made for establishing a new Joint Committee on Outer Space and for giving the jurisdiction of outer space to the present Joint Committee on Atomic Energy. It would also be possible to have separate House and Senate committees for dealing with this subject, although this idea does not seem to be "in the wind" at the present time.

The question of whether the Congress can have two joint committees working on such closely related subjects as outer space and atomic energy would seem to require the same type of analysis as that suggested in this paper for the two matching executive commissions.

(1) How closely are the subjects of outer space and atomic energy related?

(2) Would it be possible to have 2 Commissions send almost identical bills to 2 joint committees on such a subject as launching devices for long-range missiles and satellites?

(3) If there were a conflict of jurisdiction over the two joint committees, who would decide the referral of bills?

(4) If congressional jurisdiction over outer space is given to the Joint Committee on Atomic Energy, should the name of that committee be changed in accordance with its expanded terms of reference?

(5) Whether outer space is referred by the Congress to its present Joint Committee, or to a new one, how will the committee work with other congressional committees which have a primary interest in legislation on such subjects as weather control, communications, navigation, education, and national defense?

(6) Could more coordination in the Congress be achieved by having permanent House and Senate standing committees with representative membership similar to that of the present special committees?

[H. R. 11881, 85th Cong., 2d sess.]

A BILL To provide for research into problems of flight within and outside the earth's atmosphere, and for other purposes

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That this Act may be cited as the "National Aeronautics and Space Act of 1958".

DECLARATION OF POLICY

SEC. 2. The Congress hereby declares that the general welfare and security of the United States require that adequate provision be made for research into, and the solution of, problems of flight within and outside the earth's atmosphere and that provision also be made for the development, testing, and operation for research purposes of aircraft, missiles, satellites and other space vehicles, manned and unmanned, together with associated equipment and devices. The Congress further declares that such activities should be directed by a civilian agency exercising control over aeronautical and space research sponsored by the United States, except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations, in which case the agency may act in cooperation with, or on behalf of, the Department of Defense These activities should be conducted so as to contribute materially to one or more of the following policy objectives: (1) the expansion of human knowledge of phenomena in the atmosphere and space, (2) the improvement of the usefulness, performance, safety, and efficiency of aircraft, (3) the development and operation of vehicles capable of carrying instruments, equipment, and living organisms through space, (4) the preservation of the role of the United States as a leader in aeronautical and space science and technology, (5) the making available to agencies directly concerned with national defense of discoveries that have military value or significance, (6) cooperation by the United States with other nations and groups of nations in work done pursuant to this Act and in the peaceful application of the results thereof, and (7) the most effective utilization of the scientific and engineering resources of the United States and the avoidance of duplication of facilities and equipment.

NATIONAL AERONAUTICS AND SPACE AGENCY

SEC. 3. There is hereby established the National Aeronautics and Space Agency, hereinafter called the "Agency". The Agency shall be headed by a Director who shall be appointed by the President by and with the advice and consent of the Senate, shall receive compensation at the rate of $22,500 per annum, and, except as otherwise provided in this Act, shall exercise the functions of the Agency. The Director may from time to time make such provisions as he may deem appropriate authorizing the performance by any officer, employee, or administrative unit under his jurisdiction of any of his functions under this Act.

NATIONAL AERONAUTICS AND SPACE BOARD

SEC. 4. (a) There is hereby established the National Aeronautics and Space Board, hereinafter called the "Board", which shall be composed of not to exceed seventeen members appointed by the President.

(1) No more than eight of the members of the Board shall be designated from appropriate departments or agencies of the Government of the United States, including at least one who shall be from the Department of Defense

(2) Members of the Board other than those appointed under subsection (a) (1) of this section shall be eminent in science, engineering, technology, education, or public affairs and shall be selected solely on the basis of established records of distinguished achievement, and shall be appointed for terms of four years from the date of expiration of the terms of the members whom they succeed, except that in making initial appointments of such members the President may make appointments for such shorter terms as he deems appropriate.

(b) The Chairman of the Board shall be designated from time to time by the President from among the members appointed under subsection (a) (2) of this section. Such members shall be paid travel expenses and per diem in accordance with the provisions relating to persons serving without compensation under section 5 of the Administrative Expenses Act of 1946, as amended (5 U. S. C. 73b–2).

FUNCTIONS OF THE BOARD

SEC. 5. (a) The Board shall meet at least four times each year and shall advise the President and the Director concerning policies and programs of the Agency. The Board shall make an annual report and from time to time such other reports to the President as it deems appropriate

(b) The Board may make recommendations to the President with respect to the appointment of the Director, and the Director shall not be appointed until the Board shall have had a reasonable opportunity to make such recommendations

(c) The Board shall be consulted by the Director prior to—

(1) initiation or substantial modification of policies or programs of the Agency,

(2) transmittal of any request for appropriations to the Bureau of the Budget pursuant to the Budget and Accounting Act, 1921, as amended (31 U S C 1 et seq);

(3) establishment of major constituent organizational units of the Agency, and the assignment of major functions or groups of functions thereto; and

(4) appointment by the Director of the heads of major constituent units.

FUNCTIONS OF THE AGENCY

SEC 6. (a) The Agency shall—

(1) develop a comprehensive program of research in the aeronautical and space sciences;

(2) plan, direct, and conduct scientific studies and investigations of the problems of manned or unmanned flight within or outside the earth's atmosphere with a view to their practical solution,

(3) develop, test, launch, and operate aeronautical and space vehicles;

(4) arrange for participation by the scientific community in planning, scientific measurements and observations to be made through use of aeronautical and space vehicles, and conduct or arrange for the conduct of such measurements and observations, and provide as appropriate for dissemination of data collected, and

(5) submit to the President for transmittal to the Congress an annual report of operations and accomplishments.

(b) In performance of the above functions the Agency is authorizes—

(1) to make, promulgate, issue, rescind, and amend rules and regulations governing the manner of its operations and the exercise of the powers vested in it by law;

(2) subject to the civil service laws, to select, appoint, employ, and subject to such regulations as the President may prescribe and without regard to the Classification Act of 1949, as amended (5 U. S. C 1072 et seq), and the Federal Employees Pay Act of 1945, as amended (5 U S. C. 901 et seq), fix and adjust, as nearly as consistent with the public interest and on the basis of equal pay for equal work at rates which are reasonably comparable with prevailing rates paid by non-Federal employers for similar work, compensation of such officers and employees as may be necessary to carry out the provisions of this Act,

(3) to acquire, construct, improve, repair, operate, and maintain laboratories, research and testing sites and facilities, manned and unmanned aeronautical and space vehicles, quarters and related accommodations for employees and dependents of employees of the Agency, and such other real and personal property, or any interest therein, as the Agency deems necessary within and outside the continental United States, to lease to others such real and personal property; to sell and otherwise dispose of real and personal property in accordance with the provisions of the Federal Property and Administrative Services Act of 1949, as amended (40 U. S. C 471 et seq.), and to provide by contract or otherwise for cafeterias at its installations and to purchase and maintain equipment therefor, the receipts therefrom shall be deposited to a special fund in the Treasury which shall remain available for obligation and expenditure in connection with such operations and purchase and maintenance of equipment,

(4) to accept gifts or donations of services, money, or property, real, personal or mixed, tangible or intangible, and to make grants to further the authorized purposes of the Act,

(5) without regard to section 3648 of the Revised Statutes, as amended (31 U. S. C. 529), to enter into and perform such contracts, leases, cooperative

agreements, or other transactions as may be necessary in the conduct of its work and on such terms as it may deem appropriate, with any agency or instrumentality of the United States, or with any State, Territory, or possession, or with any political subdivision thereof, or with any person, firm, association, corporation, or educational institution,

(6) to use with their consent the services, equipment, personnel, and facilities of Federal and other agencies with or without reimbursement and on a similar basis to cooperate with other public and private agencies and instrumentalities in the use of the services, equipment, and facilities of the Agency. In addition to authority to use provided by this subsection and, notwithstanding any other provision of law, any governmental agency or component thereof is authorized to transfer to the Agency, without reimbursement, supplies, equipment, aircraft, missiles, space vehicles, and related parts other than administrative supplies or equipment,

(7) to appoint such advisory committees as may be appropriate for purposes of consultation and advice to the Agency in performance of its functions,

(8) to obtain services as authorized by section 15 of the Act of August 2, 1946 (5 U. S C. 55a), at rates not to exceed $100 per diem,

(9) when determined by the Director to be necessary and subject to such security investigations as he may determine to be appropriate, to employ aliens without regard to statutory provisions prohibiting payment of compensation to aliens,

(10) to employ and compensate retired commissioned officers of the United States at the rate established for the positions so occupied by them within the Agency, less the amount of their retired pay *Provided*, That, when the retired pay amounts to or exceeds the rate of compensation established for the position occupied, such person shall be entitled to the pay of the Agency position, or the retired pay, whichever he may elect;

(11) with the approval of the President, to enter into cooperative agreements under which members of the Army, Navy, Air Force, and Marine Corps may be detailed by the appropriate Secretary for services in performance of functions under this Act to the same extent to which they might be lawfully assigned in the Department of Defense,

(12) to the extent the Director finds it will contribute to achievement of the objectives of this Act or to the more effective functioning of the Agency, to conduct or provide training and to assign employees to research, study, or training at Federal or non-Federal facilities, including public or private agencies, institutions of learning, laboratories, industrial or commercial organizations, or other appropriate organizations or institutions, foreign or domestic, and, if the Director deems it appropriate, to pay in whole or in part, the following: The salaries of such employees for the periods of such training or assignments: the cost of their transportation and per diem in lieu of subsistence in accordance with the Travel Expenses Act of 1949, as amended (5 U S C 834 et seq), necessary expenses incident to their training or assignment, including tuition, fees, study materials, and other customary expenses The Agency shall require any employee who accepts such a leave or assignment to agree in writing to return to and, unless involuntarily separated therefrom, to remain in the service of the Agency for a period equal to three times the length of any time off with pay granted such employee without charge to annual leave for the purpose of such training or assignment. Any employee who fails to fulfill such agreement shall be required to reimburse the Government for whatever portion the Director determines to be equitable of the transportation, per diem in lieu of subsistence, and other expenses incident to such training or assignment paid by the Government To the extent authorized by the Director, contributions may be made by private sources and accepted by employees receiving training in non-Federal facilities without regard to the provisions of section 1914 of title 18 of the United States Code;

(13) to authorize employees to attend meetings concerned with functions or activities of the Agency including improved conduct, supervision, or management of such functions or activities, and to pay the whole or any part of the expenses of such attendance,

(14) (a) to consider, ascertain, adjust, determine, settle, and pay, on behalf of the United States, any claim for money damage of $5,000 or less against the United States for bodily injury, death, or damage to or loss of real or personal property resulting from the conduct of the Agency's functions as specified in subsections 6 (a) (2), (3), and (4), where such claim is presented to the Agency in writing within two years after the accident or incident out of which the claim arises;

(b) if the Agency considers that a claim in excess of $5,000 is meritorious and would otherwise be covered by this subsection it may pay the claimant $5,000 and report the excess to Congress for its consideration;

(c) except as provided in (b) of this subsection, no claim may be paid under this section unless the amount tendered is accepted by the claimant in full satisfaction.

(15) to arrange with the Civil Service Commission for the conduct of appropriate security or other personnel investigations of employees of the Agency, contractors and subcontractors, and their employees, as the Director deems necessary in the conduct of official functions of the Agency: *Provided*, That in the event an investigation made under this authority develops any data reflecting that the individual who is subject of the investigation is of questionable loyalty, the matter shall be referred to the Federal Bureau of Investigation for the conduct of a full field investigation, the results of which will be furnished to the Agency;

(16) to direct such of its officers and employees as it deems necessary in the public interest to carry firearms while in the conduct of their official duties. The Agency may also authorize such of those employees of its contractors engaged in the protection of property owned by the United States and located at facilities owned by or contracted to the United States, as it deems necessary in the public interest, to carry firearms while in the conduct of their official duties.

SECURITY

SEC. 7. (a) The Atomic Energy Commission may authorize access to Restricted Data by the Atomic Energy prospective contractor, licensee or prospective licensee of the Atomic Energy Commission or any other person authorized access to the Restricted Data by the Atomic Energy Commission under subsection 145 b. of the Atomic Energy Act of 1954, as amended (42 U. S. C. 2163), to permit any member of the Board or an advisory committee, or any officer, employee, contractor, or employee of a contractor of the Agency to have access to Restricted Data required in the performance of his duties and so certified by the Director: *Provided, however*, That the Director or his designee has determined, in accordance with the established personnel security procedures and standards of the Agency, that permitting the member of the Board or an advisory committee, or employee, contractor, or employee of a contractor to have access to such Restricted Data will not endanger the common defense and security: *And provided further*, That the Director finds that the established personnel and other security procedures and standards of the Agency are adequate and in reasonable conformity to the standards established by the Atomic Energy Commission under section 145 of the Atomic Energy Act of 1954, as amended (42 U. S. C. 2165).

(b) Whoever willfully shall violate, attempt to violate, or conspire to violate any regulation or order as shall be promulgated by the Director for the protection or security of any laboratory, station, base or other facility, or part thereof, or any aircraft, missile, spacecraft or similar vehicle existing, or later conceived, or part thereof, or other property or equipment in the custody of the Agency shall be guilty of a misdemeanor and upon conviction thereof shall be liable to a fine of not to exceed $5,000, or to imprisonment of not more than one year, or both, except that whoever commits such an offense with intent to injure the United States or with intent to secure an advantage to any foreign nation, shall, upon conviction thereof be punished by a fine of not more than $20,000 or by imprisonment for not more than twenty years or both.

(c) Section 1114 of title 18, United States Code, is hereby amended by striking our "or any officer or employee of the Indian field service of the United States," and inserting in lieu thereof "any officer or employee of the Indian field service of the United States, or any officer or employee of the National Aeronautics and Space Agency directed to guard and protect property of the United States under administration and control of the National Aeronautics and Space Agency."

TRANSFER OF RELATED FUNCTIONS

SEC. 8. For a period of three years after the effective date of this Act, the Agency, with the concurrence of the head of the department or agency concerned and with the approval of the President, may transfer to itself any functions (in-

cluding powers, duties, activities, facilities, and parts of functions) of such department or agency or of any officer or organizational entity thereof which relate primarily to the functions of the Agency as set forth in section 6 hereof. In connection with any such transfer the President may, under authority of this section or under other applicable authority, provide for appropriate transfers of records, property, civilian personnel, and funds.

APPROPRIATIONS

SEC. 9. (a) There are hereby authorized to be appropriated without fiscal year limitation such sums as may be necessary and appropriate for the carrying out of the provisions and purposes of this Act

(b) Any funds appropriated for the construction of facilities may be used for emergency repairs of existing facilities when such existing facilities are made inoperative by major breakdown, accident, or other circumstances and such repairs are deemed by the Director of the Agency to be of greater urgency than the construction of new facilities.

NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS

SEC. 10. (a) The National Advisory Committee for Aeronautics on the effective date of this Act shall cease to exist as such and all real and personal property, personnel, funds, and records of that organization are hereby transferred to the Agency. The Agency shall wind up any outstanding affairs of the National Advisory Committee for Aeronautics not otherwise provided for in this Act. Except as otherwise directed by the President, the members of the National Advisory Committee for Aeronautics shall serve as the members of the National Aeronautics and Space Board until their successors are appointed by the President as provided in section 4 of this Act.

(b) Section 2302 of title 10 of the United States Code is amended by deleting the phrase "or the Executive Secretary of the National Advisory Committee for Aeronautics." and by inserting in lieu thereof the phrase "or the Director of the National Aeronautics and Space Agency"; and, section 2303 of said title 10 is amended by deleting the phrase "The National Advisory Committee for Aeronautics." and by inserting in lieu thereof the phrase "The National Aeronautics and Space Agency.".

(c) Section 1 of the Act of August 26, 1950 (5 U. S. C. 22–1), is amended by deleting the phrase "National Advisory Committee for Aeronautics" wherever it appears and by inserting in lieu of the deleted words, in each instance, the phrase "National Aeronautics and Space Agency"

(d) The Unitary Wind Tunnel Plan Act of 1949 (50 U. S C 511) is amended by deleting the phrase "The National Advisory Committee for Aeronautics (hereinafter referred to as the 'Committee')" and by inserting in lieu thereof the phrase "The National Aeronautics and Space Agency (hereinafter referred to as the 'Agency')" and is further amended by deleting the word "Committee" wherever it appears and by inserting in lieu thereof, in each instance, the word "Agency"

(H. R. 11882, Mr. Arends, of Illinois; H. R. 11887, Mr. Haskell, of Delaware; H. R. 11888, Mr. Keating, of New York; H. R. 11961, Mr. Frelinghuysen, of New Jersey; and H. R. 11964, Mr. Fulton, of Pennsylvania, are identical with H. R. 11881.)

The CHAIRMAN. This is the opening of the public hearings of the Select Committee on Astronautics and Space Exploration, adopted by the House of Representatives in an amendment and appointed by the Speaker.

We are fortunate in having before us as a first witness a very distinguished gentleman, dedicated to the way of peace and to the preservation of the way of life that free men and free women believe in and want and seek and desire.

I refer to Dr. Wernher von Braun.

We are happy to have you with us, Doctor, and shall be very glad to hear your testimony.

Have you a prepared statement?

Dr. VON BRAUN. Yes, sir.

The CHAIRMAN. We will be glad to hear it.

STATEMENT OF DR. WERNHER VON BRAUN,[1] DIRECTOR, DEVELOPMENT OPERATIONS DIVISION, ARMY BALLISTIC MISSILE AGENCY, HUNTSVILLE, ALA.

Dr. VON BRAUN. It is a pleasure to appear before you today. I am Director of Technical Development at the Army Ballistic Missile Agency, and as such I am happy to represent our fine team of development engineers and scientists. Let me assure you that our usage of the word "team" is not restricted only to those of us who came to this country from Peenemunde, but now encompasses the many engineers and scientists, both civilian and military, with whom we have joined in the development of the Redstone and Jupiter missiles. After giving you a brief summary of the activities of our team, I will be fully responsive to your questions.

The experience of our team begins in the 1930's in Germany, and includes development of the V–2 missiles of World War II. Since those days our work on ballistic missiles has proceeded at an ever-increasing pace. The V–2 required many years of development before it was successfully fired in 1942; then, 2 more years were required before the V–2 was a useful weapon. Even then it was a crude device when measured against such missiles as Redstone and Jupiter.

Before the end of World War II it became apparent to our group that we must sooner or later choose between capture by the Russian Army and surrender to the American Army. The choice of the majority, as you know, was to surrender to the American Army. That choice has extended to full citizenship for the majority of our group.

We are proud of work in behalf of our country. The Redstone has already proven itself a workhorse missile, readily adaptable to a variety of uses. Jupiter is progressing through its developmental stage at a very satisfactory pace, and promises to duplicate the reliability of the Redstone.

Looking into the future, we believe that it is necessary to recognize the interrelation of ballistic missiles, satellites, and space travel. The basic elements are the same—rocket engines, structures, guidance and control devices, as well as certain ground support facilities. The mastery of space depends on the same resources as the development of ballistic missiles. But this does not mean that it will be a natural and automatic byproduct of the latter. Indeed, the very scope of the exploration of outer space is so vast as simply to preclude its being the byproduct or fallout of anything. We can meet this challenge only if we appreciate and respect the magnitude of this task and discontinue our unfortunate practice of supporting only such research and development that serves immediate military objectives.

The research and development requirements ahead of us are so vast

[1] Von Braun, Wernher, engr , b Wirsitz, Eastern Germany, Mar 23, 1912 s Baron Magnus and Emmy (von Quistorp) Von B , student Inst Tech , Zurich, Switzerland, 1931 B S , Inst Tech , Berlin, Germany, 1932; Ph D , U Berlin, 1934, m Maria Von Quistorp, Mar 1, 1947, 2 daus , Iris, Margrit Came to U S , 1945, received 1st citizenship papers 1950 Asst to Prof Oberth, Mediasch, Roumania, 1930, experimenting with small liquid fuel rocket motors, Berlin-Ploetzensee, founding mem Rocket Field Berlin, small rocket exptl sta , sponsored and financed by German Rocket Soc , 1930, liquid fuel rocket expert German Ordnance Dept , Kummersdorf, 1932–37, tech dir German Rocket Research Center, Peenemuende, Baltic Sea, 1937–45, research prof Peenemuende, 1943–45, responsible for development of V–2 Long Range Rocket and A A. Guided Missile Wasserfall, 1937–45. Y C) Home 907 McClung St. Office Development Div , Redstone Arsenal, Huntsville, Ala

that there should be no question in anyone's mind about a shortage of workload for any of the qualified development teams. It may be wise to have some overlapping of programs and to instill a bit of competition between teams. However, we must carefully retain the present atmosphere of free and full exchange of information in order to avoid costly duplication of effort and to provide for mutual assistance between teams. Also, our scientists should be free to pursue their efforts without continual worry about a program cancellation putting them out of business and thus destroying the team they have built up. The ABMA record of accomplishment for money spent is full evidence that waste will not occur if the existing well-qualified development teams of the country are kept together and allowed to pursue their goals under competent management in a coordinated program.

The Russians have shown clearly their recognition of the importance of the entire field of rocket-propelled devices leading to space control. They have further shown an understanding of the interrelation between scientific and military programs in the entire field. Vigorous action is required to overcome as quickly as possible the obvious lead which the Russians now enjoy.

Gentlemen, this will not be easy, but it must be done. This has been a very brief opening statement, and I will now be pleased to respond to your questions.

The CHAIRMAN. Doctor, in connection with your last statement about the efforts that must be made to overcome the obvious lead which the Russians now enjoy, can you elaborate upon that?

Dr. VON BRAUN. Sir, I consider the greatest single threat in the Russian position in ballistics missiles and space flight the fact that the momentum of their development effort at this time is evidently greater than ours.

When you look back at the low state of general technology evidenced by Soviet Russia at the end of World War II, and when you consider, in addition to that, the tremendous damage inflicted upon Soviet industry by the war itself, I think nobody can seriously doubt that the Russian rate of progress is faster in the field of advanced technology than ours.

This holds not only for ballistic rockets and guided missiles and satellite vehicles, but also for things like jet aircraft.

The CHAIRMAN. How do you account for their progress being more rapid than ours? We have the brains and we have the facilities?

Dr. VON BRAUN. Sir, I believe the most important single reason lies in the fact that right after the war the Russians did not return to the production of consumer goods whereas this country did. Russia kept her war production machinery going full blast after the war despite the fact that the civilian population of Russia probably would have enjoyed the production of consumer goods at least as much as the people in this country It was all merely a question of emphasis.

The CHAIRMAN. I will have some questions later. Mr. Brooks, do you have any questions to ask?

Mr. BROOKS. No questions.

The CHAIRMAN. Mr. Hays, do you have any questions?

Mr. HAYS. No questions at this time.

The CHAIRMAN. Mr. O'Brien?

Mr. O'BRIEN. I would like to ask one question, Doctor.

We know that the Russians now have no satellite in space. Do

you believe that they are at the moment planning something new and spectacular and beyond what they have already demonstrated?

Dr. VON BRAUN. I am convinced of that; yes, sir.

Mr. O'BRIEN. Thank you.

The CHAIRMAN. Congressman Natcher?

Mr. NATCHER. Doctor, in establishing a national space exploration program, I think it is imperative that we decide what steps and methods are feasible and expedient and what priority must be established for such a program.

In your opinion, Doctor, should this be a "crash" program? How should it start?

Dr. VON BRAUN. Sir, if you mean by a crash program a temporary effort merely to make up for time lost in the past, then I am against a crash program.

If you mean a sustained effort, without any hot and cold blowing, but sustained and adequately supported over a period of 10 or 15 years, then I am all for it.

Mr. NATCHER. Thank you, sir.

The CHAIRMAN. In other words, you mean an intensive accelerated program. Is that the way you put it?

Dr. VON BRAUN. Yes, sir; I think this country should put a great effort into a space program. But even more important than the budget figures for the first year is the question of how we can stabilize this program and keep it going at a sustained, accelerated rate over a number of years, how we can eliminate this lethal and wasteful hot-and-cold blowing that has plagued all our missile projects in the past.

I think this lack of steady determination and unwaivering support over the years has hurt us more than anything in the past.

The CHAIRMAN. Mr. Sisk?

Mr. SISK. Dr. von Braun, at what stage did Russia surpass us in missile and rocketry? You state that apparently they are in the lead today. I am curious to know.

You know there have been many statements made. When in your opinion did Russia surpass our efforts, our development, and our knowledge?

Dr. VON BRAUN. Sir, I do not think you could pin this down to a certain date, but they are quite obviously ahead of us now. We have ample evidence that the Russians have ICBM's successfully flying over a range of many thousand miles, whereas we have not.

It is further obvious that the Russians have used such ICBM rockets to launch their two sputniks into orbit. Both of these sputniks, particularly Sputnik No. 2, are many times heavier than our own satellites. Out little Explorers and Vanguards are competing with the sputniks in spirit only. But in terms of rocket hardware they are no match.

Mr. SISK. Doctor, you were leader of a team doing basic research on what we call the Redstone and the later Jupiter. In the development, when did you feel that you had accomplished sufficient basic research to give you information that the weapon could have been used to put a satellite in space?

Dr. VON BRAUN. We fired a three stage vehicle, using the Redstone missile as first stage, for the first time on the 20th of September 1956. It flew over a range of 3,300 miles, with a payload of 84 pounds.

Had we replaced the 84 pound payload of this missile by a fourth stage, as we later on did with the Explorers, this same missile would

have been able to orbit. Thus the earliest possible date would have been September 1956.

Since this was the very first firing of the multistage version of the Redstone, we had time to improve it since September 1956. So it is only fair to add that the chances of success of a satellite firing with this missile have continuously increased.

But nevertheless, the firing of September 1956 clearly demonstrated to us and others then and there that we had a satellite capability with this missile.

Mr. SISK. When did your work start, Doctor, your basic research on the Redstone?

Approximately what year did that work start?

Dr. VON BRAUN. Work on the Redstone started in the spring of 1951. That was when the green light was given for an active development program. Our preliminary design studies began in 1950.

Mr. SISK. Actually it took you a period of some 6 years, then, before you were able to have projected a satellite, irrespective of the size, into space; is that correct?

Dr. VON BRAUN. The Redstone missile is a field weapons system and has not been operationally ready until very recently. In fact, the first operational Redstone unit will be deployed in May 1958.

Thus the total time needed for the development of the Redstone missile system from the word "go" to deployment as a military weapons system in the field, was approximately 7 years.

A satellite capability with the Redstone missile, as I stated before, existed as early as fall of 1956 This was about 5½ years after the initiation of the Redstone program.

Mr. SISK. The thing that I was interested in, Doctor, and I have no desire to put anyone on the spot or embarrass anyone over previous statements, but it was my understanding that somewhere in 1955 it was your opinion that we were still ahead of Russia in basic research.

Frankly, that was the reason I was attempting to bring out some of these things here

Dr. VON BRAUN. Yes, sir; I am very well aware of that. I have even made statements in public to that effect.

My explanation and excuse for these statements is that at that time I did not have complete access to what we really knew about the Russian progress.

Please bear in mind that I received my American citizenship only in 1955. It was only thereafter that I gained access to our intelligence.

Mr. SISK. Doctor, I appreciate that statement. I can understand your position.

As I said, there was no intention on my part to embarrass you with this question.

Are you prepared at this time to say whether or not that intelligence indicated at what time Russia may have surpassed us, or was it just intelligence of 1955 that indicated that?

Dr. VON BRAUN. Sir, the only information I had access to prior to obtaining my American citizenship and prior to my clearance for certain classified intelligence information was based on the reports by German rocket scientists who had returned from Soviet Russia. These men were debriefed by western intelligence agents upon their return to Western Berlin or Western Germany.

The definite impression I got from these debriefings was that the Russians had made very poor use of the German scientists they had

taken into Soviet Russia and that, by and large, the Russian missile program was pretty confused and poorly administered.

It became clear to me only much later that there existed an entirely independent Soviet Russian ballistic missile development program of which the German scientists taken into Soviet Russia were not even aware.

This also answers a question frequently raised these days, namely, what was the probable contribution of German scientists working in Russia toward the sputnik program. I think the answer is "very little."

The CHAIRMAN. Mr. Arends.

Mr. ARENDS. I will pass for the moment.

The CHAIRMAN. Mr. Fulton?

Mr. FULTON. I will yield to Mr. McDonough.

Mr. McDONOUGH Dr. von Braun, do you know, or do you have any intimate knowledge of the men that built the Russian sputnik, do you know whether they are men who came from Peenemunde?

Dr. VON BRAUN. No, sir; I am convinced they did not.

As I just said, the German scientists taken into Russia were obviously not even aware of the large and extensive ballistic missile program that was going on inside Soviet Russia. From what we could gather from those debriefing reports, the German scientists were merely squeezed out; they were asked questions like, "How did you do this, and how did you do that?"

They were frequently requested to explain German reports from the Peenemunde archives that had been taken to Soviet Russia. They had to piece old equipment together, and they made lots of design and feasibility studies on paper. But they did not to any appreciable extent actively participate in the hardware phases of the rocket and missile development program in Soviet Russia.

Mr McDONOUGH. Are there any of the original Peenemunde group still inside Soviet Russia working on missiles or satellites?

Dr. VON BRAUN. To my knowledge, not any more.

Mr. McDONOUGH. You attribute the Russian sputnik to Russian scientists, mathematicians, engineers, and physicists?

Dr. VON BRAUN. Yes, sir; absolutely. I believe the Russians made extensive use of the German progress in rocket technology during the last war and whatever they learned from German scientific reports taken into Russia as war booty. But on this foundation they built their own program with their own people.

The sputniks are definitely the result of a Russian program with little if any German assistance.

Mr. McDONOUGH Can you account for, or do you have any reason to believe that there has been a hesitation in their program because they have not sent another satellite into orbit since the second sputnik, and we have sent up three? Is there any reason to believe they are waiting for something, or they have failed in their program?

Dr. VON BRAUN Sir, my personal theory is this·

Since the Russians obviously use ICBM hardware in support of their satellite program, it follows that whatever ICBM rocket hardware is available must be split between two programs, namely, their ICBM program and their satellite program.

So it would appear only logical to assume that after their space people had two successful satellite flights it is now their ICBM people's turn again to get some of the rockets.

Now, this is strictly my personel interpretation, and I must ask you to take it for what you think it is worth.

Mr. McDONOUGH. Is the thrust engine principle that is used to put a satellite into orbit the same in Russia and the United States? Are the basic principles the same?

Dr. VON BRAUN. With the exception of the Redstone that was used in support of the Explorer satellite we have not used any military rocket hardware in our United States satellite program yet.

The Vanguard, as you know, was specifically designed to support the satellite program of the International Geophysical Year. It has no military usefulness. Only in future United States satellite programs will we also utilize IRBM and ICBM rockets.

Mr. McDONOUGH. Do you know whether the Russian physicists and engineers have amplified and expanded the original Goddard theory in rocketry?

I read something about your statement concerning Goddard as one of the pioneers in rocketry and that Peenemunde was pretty much an expansion and application of his original theory.

Is that true in Russia? Did they use Goddard's basic theory in the development of their program?

Dr. VON BRAUN. Sir, I have always considered Goddard one of the three great early pioneers in rocketry, with Germany's Oberth and Russia's Ziolkowsky being the two others. These three men laid the scientific groundwork for modern rocketry. But whereas Oberth and Ziolkowsky were chiefly theorists, Goddard was also a brilliant experimenter. I think Goddard's main dilemma was that he could not find anybody to give him enough money for his more advanced rocket experimentation.

Others were a little more fortunate in this respect, the Peenemunde team in prewar and wartime Germany and the Russian rocket and satellite group today.

Mr. McDONOUGH. In other words, the basic principle of a missile or a rocket is a physical law, that both had to work on.

Dr. VON BRAUN. Yes, sir.

Mr. McDONOUGH. Neither one had the advantage of the other—except that if we can develop an engine with a large enough thrust to overcome Russia, then we are on top of her; and they do have a heavier thrust than we do at the present time?

Dr. VON BRAUN. Yes, sir. This business of large thrust rocket engines is not a question of science at all. It is simply a question of putting enough resources behind such a program to have the engines built and tested.

Mr. McDONOUGH. What is our actual thrust at the present time, do you know?

Dr. VON BRAUN. I don't know if I can answer that question in open meeting.

Mr. McDONOUGH. Also, our maximum thrust is classified information?

Dr. VON BRAUN. I should think it is, but I'll be glad to check.

Mr. FELDMAN. I believe, Doctor, that the newspapers carried the story to the effect that the Russian engines had a thrust of between 250,000 and 395,000 pounds as compared with the Vanguard which had a thrust of 40,000 pounds, and the Jupiter which had a thrust of 83,000 pounds. At least I saw that in the newspaper.

Dr. von Braun. I cannot vouch for the Russian figures you have, I can neither confirm nor deny them. But this much is certain:

Whatever rocket carried Sputnik II in orbit must have had many, many times the thrust of either the Redstone or the Vanguard. That rocket must have had several hundred thousand pounds of thrust.

Mr. McDonough. I have one other question. Mr. Chairman.

Dr. von Braun, is there any advantage in the first takeoff of a rocket, or a missle, to starting it below the surface of the earth and taking the full advantage of the thrust in an enclosure rather than on the surface?

Dr. von Braun. No, sir. There would be some advantage, theoretical advantage at least, in catapulting rockets from underground shafts in order to build up a certain initial speed with ground power.

But usually the penalty you pay for the structural reinforcements needed to handle the catapult loads nullifies the advantage gained.

Mr. McDonough. There is greater advantage in starting from the surface?

Dr. von Braun. Yes, sir.

The Chairman. Did you want to ask some questions now, Mr. Arends?

Mr. Arends. I am going to limit myself to 1 or 2 questions and observations, Mr. von Braun. You may have already answered the question before I got here. Unfortunately I was a little late.

In the second to the last paragraph in your paper, you say:

> Vigorous action is required to overcome as quickly as possible the obvious lead which the Russians now enjoy.

Can you develop that a little bit more? If you developed that with the other gentlemen, it will be in the record and I will look it up.

Dr. von Braun. Yes, I did.

The Chairman. I would like to have it developed more. Why do you not go a little further?

Mr. Arends. I would like to have all the information you can possibly give in open session. I have heard it argued one way or another that in certain fields in the intercontinental ballistic missile we may be behind; in the intermediate range we may be at a certain point. In other missiles we may be ahead of the Russians. Can you explore that a little?

The Chairman. Consistent with national security. We believe that the American public should be informed as fully as possible, the bad as well as the good, because if the American people are given information they can take it.

Mr. McDonough. There have been so many conflicting stories about this I think, to a degree at least, it should be clarified.

Dr. von Braun. Sir, I am not aware of any evidence that either in the ICBM or in the IRBM field we are in any way ahead of them. On the contrary, every available evidence that I have seen indicates that the Russians are ahead of us in both.

Where we stand in short-range missiles, I do not know.

Mr. McDonough. Let me ask you another question:

Are you satisfied with the programs and the speed of progress today as you visualize our overall program of the objective things we must do? Are you satisfied with the speed and the progress of the program as you visualize it at this moment?

Dr. VON BRAUN. Sir, I think we won't ever be satisfied in this area. I think we can always work a little faster by removing a few more obstacles.

Many new projects have been initiated since the advent of the sputniks. I think, by and large, this new program is well planned, well conceived, and in competent hands. There are, of course, many obstacles to overcome, such as making enough money available early enough for these new projects. These things just seem to take their time.

Mr. McDONOUGH. Would you say in a general way that we are putting forth full effort?

Dr. VON BRAUN. I think there is a great effort going on now. Whether that effort is adequate to build up sufficient momentum to match the Russian program in working speed and finally to overtake it, I am not prepared to say.

In fact, I have my doubts whether what we are doing is enough.

Mr. McDONOUGH. I will ask one more question. Are you in any way handicapped in your efforts by lack of sufficient funds?

Dr. VON BRAUN. Sir, may I speak for the Army ballistic missile program only?

Mr. McDONOUGH. Yes.

Dr. VON BRAUN. With your permission I would like to go into a little more detail on this. We work on three different weapons systems projects at the Army Ballistic Missile Agency at the moment. One is in its final stages. It is the completion of the fielding process of the Redstone missile system; in other words, making more and more Redstone firing units available to the troops.

As far as research and development is concerned, the Redstone program is almost complete. There are only a few limited cleanup tasks such as a winterization program going on in this area.

I do not see how this work could be expedited by more funds. It is coming along very well.

As far as our second project, the Jupiter program, is concerned, I think you know that we are developing the Jupiter system in a kind of competition with the Thor system for the Strategic Air Command of the Air Force. This program, in my opinion, is also financially as well supported as can be. For a while this program did suffer from lack of funds to get Jupiter production started in our prime contractor's plant, but these difficulties have been overcome quite recently. Right now I do not think that much more money could be wisely spent on this program.

Our third program is quite new. It is the Pershing missile system, a medium range ballistic missile system, using solid propellents. We develop Pershing for the Army.

This program in my opinion is also adequately supported moneywise. The development, production, and deployment schedules envisaged for it are sound and realistic. Pershing is not a crash program which is speeded up to the point where we would be continuously operating beyond the point of diminishing returns.

I think the Pershing program is soundly conceived and supported in every respect.

In addition to these three weapons systems programs, we have a number of specific assignments from the newly formed Advanced Research Project Agency under the Office of the Secretary of Defense.

These assignments involve special missile flights in the area of space exploration, such as satellite flights and other special space missions.

In this area I believe that as far as calendar year 1958 is concerned, we have bitten off as much as we can chew. However, it is urgently necessary that we get more money now for the procurement of basic rocket hardware which we need for our part in the national space program that we are supposed to play in calendar year 1959. We need this money now because of the long lead times involved in the procurement of large rocket engines, guidance, components and the like.

Mr. McDONOUGH. That is a very good answer, Dr. von Braun. If I understand the opinion of the Congress, it is this; that we want to give you all the money you need to do a good job, but certainly we do not want just to throw money in your lap, which, as you say, might not be well spent for the efforts you are engaged in.

The CHAIRMAN. Mr. Fulton?

Mr. FULTON. Dr. von Braun, we are glad to have you here and glad to know of your interest in the program and compliment you on being an American citizen.

You, in 1955, were in a moving picture that had quite an influence on me. It was a satellite film on developments to come. I might say, like Jules Verne's Twenty Thousand Leagues Under the Sea, it has been remarkable how everything you predicted in that 1955 film, I would like to say publicly, has come true. If we had been more alert on your warning, we could certainly, in the United States and the free world, have been further ahead.

Because of your interest I, as a commander in the Navy Reserve, have been at Cape Canaveral on duty and on various missile ships. So I am interested in your program.

Would it help you as a matter of organization to have Congress set up a committee primarily responsible in this particular field so there would be close liaison and policy guidance to you as you carry out your work? Should we in Congress have a special space committee set up so that we can work with you on a civilian basis, having regard to the military aspects and the scientific aspects both?

Would that be of help?

Dr. VON BRAUN. Sir, I believe it would be of great help indeed, and mainly for the following reason:

I think there is always the danger in a thing like the present space rush, that after the first excitement is over people might go to sleep again. Thus we may get a lot of money for 1 or 2 years, but then the space program may become ever less important as time goes on, particularly if the Russians do not come up with new surprises.

I think the most important single requirement of a sound national space program is that it be a sustained effort, so that we can really plan ahead, that we will know how much money will be available not only in 1958 but also in 1959, 1960, 1961, and 1962, and we really know that Congress and the American people mean business in taking up the Russian space challenge.

Mr. FULTON. So you would then recommend a permanent setup in Congress of a committee having primary jurisdiction of the space field, both scientific and military with the idea of setting policy for long-term national space program development?

Dr. VON BRAUN. Yes, sir.

Mr. FULTON. Would it be helpful to you in the scientific field and not in the legislative field, to have a joint committee of the Senate and the House in order that you would not have to duplicate your testimony before two bodies? Would it make it easier for the scientists involved in the program to come up before one joint committee rather than a committee of the House and a committee of the Senate?

Dr. VON BRAUN. Sir, I am not very experienced in these matters, but I think the Joint House-Senate Committee on Atomic Energy has set a very fine precedent here and has proved that it can work and work very efficiently.

Mr. FULTON. Then you would really recommend a body in the administrative branch that is a civilian body for the space agency, having cognizance a good bit like the Atomic Energy Commission would; is that about your view?

Dr. VON BRAUN. Yes, sir.

Mr. FULTON. You have recommended a change in program, that the United States should not continue research and development that serves only immediate military use. I believe that is good. I think you feel we should broaden the scope of the space program and look at it not only in the missiles and the weapons systems area, but likewise in the vehicle and space ship fields; is that right?

Dr. VON BRAUN. Yes, sir.

Mr. FULTON. May I ask on that end of it—we have about 11 programs on the weapons systems going on at the present time—would it help you if there were more liaison among the teams working on these various programs, better liaison and more interchange of scientific knowledge?

Dr. VON BRAUN. Yes, sir; I think improvement in this area is definitely possible, although there is more liaison than most people realize.

For example, we are continuously exchanging information and experience on flight results between the competitive Jupiter and Thor programs and at Cape Canaveral there are regular visits between firing crews engaged in different programs.

Mr. FULTON. Is the Government supplying you with enough translated material and research material that appears in various magazines over the world so that you are not hampered in your agency.

Dr. VON BRAUN. We believe there is a particular lack of good information coming over from Russia. Time and again we found out, rather belatedly, that things which hit people in this country by surprise had been published in Russian trade journals or professional magazines as early as a year before we heard about it.

Mr. FULTON. Would you recommend in the Library of Congress, or some agency of the Government, that there be set up an agency which takes primary responsibility on seeing that the scientific developments of the world are brought in and made available to people working on these projects such as you?

Dr. VON BRAUN. Yes, sir.

Mr. FULTON. Let me ask you specifically on a couple of programs. In order to have military capability in outer space, it would be, of course, best to have a space platform of some size that could be manned. How long would it take you people to put up a space platform if you started into a program with adequate means supplied by Congress?

25973—58——3

The CHAIRMAN. And, of course, the instructions to go ahead.

Mr. FULTON. And the instructions to go ahead; that is right.

Dr. VON BRAUN. Sir, I think instead of using the term "manned space platform", one should use the expression "manned orbiting vehicles of any kind or shape."

Mr. FULTON. I was trying to get away from the weapon itself, or the missile. Let us call it a vehicle.

Dr. VON BRAUN. I suggest this change in terminology because there has been some argument as to whether a space platform without any capability of maneuvering from one fixed orbit to another would not be a bit vulnerable, just like a modern airbase. Many military planners believe that a smaller orbital vehicle with reconnaissance or even bombing capability, that would go around the earth only a few times and then land, would be more effective.

Thus, to answer your question about our earliest military capability in outer space we should disregard the schedule for a large space platform which is essentially nothing but a housing facility in outer space which provides people with working and sleeping quarters. Your question would then simply be: "How about warfare from an orbit?"

Mr. FULTON. How soon could you put up a manned vehicle that orbits?

Dr. VON BRAUN. Is your question directed at the Army Ballistics Agency?

Mr. FULTON. I would say to you personally. If you were given the go-ahead and as Mr. McCormack very accurately says, the instructions to go, how soon could you put up a manned vehicle that orbits around the earth?

Dr. VON BRAUN. I think within about 2 to 3 years we could put a man into orbit and get him back alive. It would take about 5 years to have an orbital vehicle with a limited military capability.

Mr. FULTON. That actually would take less thrust than it takes to get a rocket either to hit or orbit the moon, would it not?

Dr. VON BRAUN. To go from an orbit around the earth to the moon takes less thrust. If you want to go from the surface of the earth direct to the moon and back, it would take more.

Mr. FULTON. How soon can you put a rocket up that will try for the moon, either to hit it or to orbit?

Dr. VON BRAUN. To hit the moon and even more so to orbit around the moon, is not so much a problem of having the rocket power, but of having a sufficiently accurate guidance system.

Mr. FULTON. We really could at this point aim a rocket at the moon, if we did not care whether it missed on mathematical calculations right at this time, could we not?

Dr. VON BRAUN. Yes, sir; within a relatively short period of time it will be possible to shoot the small top stage of a large multistage rocket even past the moon and out into interplanetary space so that it permanently escapes the gravitational pull of the earth.

This is simpler than hitting the moon.

Mr. FULTON. Why do we not try to ask the President to give you that power to take a crack at the moon even though you do not hit it? Would you like that?

You see, the trouble with us in the Vanguard was that we were so careful and we were trying to get it with such precise scientific instru-

mentation in it and likewise to have the solar energy to keep the batteries going 3 weeks that the Russians beat us.

Why not take the crack at the moon on mathematical calculations?

Dr. von Braun. The Advanced Research Project Agency has recently approved just such a program and we are working on it at the Army Ballistic Missile Agency right now.

Mr. Fulton. Now, you are not holding it back to make it so accurate that you will not make a mistake while the Russians go ahead on something very daring and get ahead of us? That is what I am afraid of.

Dr. von Braun. I suggest you direct any more questions you may have in this area to Dr. York, who sits right next to me.

Mr. Fulton. You have the thrust right now that you could, with the proper calculations, make a pretty good miss at the moon; do you not?

Dr. von Braun. Yes, sir.

Mr. Fulton. Then why do you not do it? Why are you waiting all this time to get instrumentation and all the things you are talking about orbiting and coming in a U-shape around the moon and back?

Dr. von Braun. We are not waiting for that. We are moving precisely in the direction you indicated.

Mr. Fulton. How soon do you think we will be taking a crack at the moon?

Dr. von Braun. To hit the moon, or pass it?

Mr. Fulton. We have the capability right now. We could go down too.

Dr. von Braun. We are working on this project as fast as we can, sir.

Mr. Fulton. Why stop at orbiting now? Why not just try it?

Dr. von Braun. We will try to shoot past the moon as soon as we have the capability. It is essentially a question of engineering, building the missiles, testing them and checking them out on the ground. We shall fire them as soon as they are ready.

Mr. Fulton. At what speed did you orbit the various vehicles that you have now?

Dr. von Braun. Approximately 18,000 miles an hour.

Mr. Fulton. So you only have to get the instrument 7,000 miles an hour faster until it does an exit performance?

Dr. von Braun. Yes, sir.

Mr. Fulton. Then why do you not get some astronomers and they will calculate where the moon is going to be at a certain point?

Dr. von Braun. Our problem is that in order to get those additional 7,000 miles an hour we need a different missile than our Jupiter C. We cannot do it with the same basic missile that put the Explorer up there. That extra speed requires the development of some new missile hardware and we are working on this right now.

Mr. Fulton. Once you get a thing like a projectile into outer space, why is that not good enough? Why do you do all this development? I am talking more of what the public thinks.

You are being so careful and making so sure it is accurate that maybe the Russians will take a bang at the moon and hit it first.

Dr. von Braun. They may very well do just that. There is nothing we can do about it. You can rest assured, sir, that we are doing it with the simplest available means and as fast as we can.

Mr. FULTON. You have the thrust right now to get out of the earth's atmosphere; you have the speed to do it; you have the instruments down there at Cape Canaveral to get out of the atmosphere, so why do you not very quickly just take a target shot?

Dr. VON BRAUN. We got the green light to do this just 2 weeks ago. Projects of this magnitude involve lead times. We have to procure things. We have to design things. We have to test them out. Otherwise it does not work.

Mr. FULTON. How long after you were told to go ahead—after the Vanguard had its sputternik—how long did it take you to put an instrumented vehicle in orbit around the earth's surface?

Dr. VON BRAUN. Eighty-four days.

Mr. FULTON. Can you do the same on the moon?

Dr. VON BRAUN. No.

Mr. FULTON. How many days?

Dr. VON BRAUN. Sir, I would rather answer that question after it has been done.

Mr. FULTON. I didn't say hit the moon, but you can already get out of the earth's atmosphere now. How soon, in days, could you take an aim at the moon even if you miss?

Dr. VON BRAUN Sir, there is a fundamental difference between this task and our Explorer I satellite firing. In the case of Explorer I we took a reentry test vehicle that was already in existence and we quickly revamped it for a satellite firing. That is why it could be done in 84 days

In the case of a shot at the moon, hit or miss, we have to start at the bottom. Maybe even here we do not have to start quite from scratch, but we still have to do a lot more basic design, manufacturing, testing and computing work and this requires many months.

Mr. FULTON. Actually, the apogee we have with our present vehicle that is orbiting is 1,500 to 2,000 miles, which is much higher than the Russians ever got; is it not?

Dr. VON BRAUN Yes, sir.

Mr. FULTON. Likewise we are using solar energy and they never used solar energy in any of their vehicles; did they?

Dr. VON BRAUN. Not to our knowledge

Mr FULTON Thank you very much.

The CHAIRMAN. Mr. Keating

Mr. KEATING. Dr. von Braun, one of the problems which this committee will want to consider will be the legislation which was introduced by the chairman and others relating to the establishment of a new space agency. You have already made one comment on that.

Do you have any other comments or views for our committee as regards legislation?

Dr. VON BRAUN. Sir, I replied to a question about the committee organization within the Congress, there is also the question of that new Astronautics and Space Act and NACA's future role in our national space program.

Mr. KEATING. The question is whether and in what respects it could be meshed into the work you are doing and whether the legislation that has been proposed is adequate to meet the problems.

It may be that you have not studied it enough to give us help, but it would certainly be well received, if you could.

The CHAIRMAN. Any questions asked, Doctor, of any of the witnesses which they would like to consider and answer later, they may do so. You will have an opportunity to edit your replies. That will be afforded all witnesses.

If you cannot answer it and it is not classified, you can state that you will be glad to answer that later when you are editing your testimony?

Dr. VON BRAUN. Yes, sir. I do not believe that the question asked by Congressman Keating involves any classified matter.

The CHAIRMAN. I was not referring to that particular question. I am just making that statement so that you gentlemen will understand.

Dr. VON BRAUN. Yes, sir. I am familiar with the administration bill called the Astronautics and Space Act of 1959. This act in essence proposes to build the astronautics and space agency around what is presently the National Advisory Committee for Aeronautics.

My personal reaction is that I find myself in basic agreement with this bill. However, I think the success of the space agency will greatly depend on the authority vested in it, and I do not believe under the present NACA charter NACA or its legal successor would be quite prepared to handle a program of this magnitude. I strongly believe that it will be necessary to put a few more teeth into the NACA charter to make it capable of handling this space assignment.

On the other hand, if these teeth are really put into the NACA charter, and if NACA would really be handed the money to run an adequate space program, then I could not think of a better solution, or of a more competent nucleus for a space agency.

Mr. KEATING. Could you be any more specific at this point? I realize that it is perhaps too early for you to say, but could you be any more specific about what you mean by "teeth in it?" Do you mean by that there should be provisions in the legislation which this committee should consider?

Dr. VON BRAUN. Sir, to put it in very broad terms NACA, as the name implies, has so far been an advisory committee for aeronautics which means the emphasis has been on "advice."

In addition to furnishing advice NACA has provided research support for projects carried out by the aircraft industry. This work has been performed in NACA's wind tunnels, structural laboratories, propulsion-test facilities, and so forth.

It is my opinion that if the newly formed National Astronautics and Space Agency is really to run a national space program, it must be given enough authority and an adequate managerial staff to centrally administer such a large and costly program. My feeling is that in order to handle this assignment, the National Astronautics and Space Agency would need a charter like that of the Atomic Energy Commission, in lieu of the charter under which NACA presently operates.

Anything short of that would probably not work out so well. After all, there is a tremendous amount of money involved in these projects, and an adequate administration of this program requires a large program management staff as well as a group of executives who can make decisions, which, incidentally, sometimes may be quite painful.

Mr. KEATING. You do not envision any difficulties or interference with the military effort in this field by the provisions of this bill as it now is drawn? You think it is perfectly possible to give proper

recognition and cognizance to what our military are doing in this field under the provisions of this bill?

Dr. VON BRAUN. Sir, I think NACA's record proves beyond a shadow of a doubt that for many years it worked very smoothly with the military services.

Likewise, the Atomic Energy Commission, also a civilian agency, has established a splendid record in working with the military services and in responding to their requirements.

I think all this is merely a question of sound administration, of proper spirit and of a good charter. I believe there is no need to fear a basic conflict between a civilian agency and the military services.

Mr. KEATING. Thank you very much.

The CHAIRMAN. Doctor, what do you gentlemen who are specialists generally consider the field of outer space or space exploration, how many miles from the earth? Generally speaking. Would it be 100 miles, 200 miles, or what?

Dr. VON BRAUN The atmosphere just gets thinner and thinner the higher you go. There is no clear-cut upper end.

People have agreed to refer to outer space when an altitude has been reached where our most sensitive instruments can no longer indicate the presence of any air.

But as our instruments have become more sensitive the altitude of the atmosphere has continuously gone up.

The CHAIRMAN. Mr. Ford.

Mr. FORD. Dr. von Braun, in your prepared statement you indicate that it is wise to have some overlapping in various missiles and possibly satellite programs. At the same time you caution against avoiding costly duplication.

Would you care to comment whether or not the Jupiter and Thor programs as they developed fell into the proper category? Can you define a good program?

Dr. VON BRAUN. Sir, first and foremost, much of this is a question of priority, of national importance. When there is a very urgent need to get a weapons system in operation as soon as possible it is always a good idea to have two sources and a certain amount of competition.

I think both the Jupiter program and the Thor program have been effectively speeded up simply on account of the existence of the other. It is just plain good business to have competition.

But in addition one should never forget that we all are continuously taking grave risks in these new missile programs. Any one of our missile makers may all of a sudden run into some kind of unexpected technical trouble that may delay the field deployment of his weapons system by as much as a year.

By having two IRBM programs and two ICBM programs we are just playing it safe.

Now it has been said that the Jupiter and the Thor are very similar because their basic military characteristics, expressed in terms of maximum range and payload carrying ability are the same. However, when it comes to details, there are many and most important differences.

The Jupiter has an entirely different nose cone, both in design and material.

The Jupiter has an entirely different guidance system from the Thor. Even the airframes of the two missiles are built along entirely different lines.

The supporting ground equipment is built on a different philosophy. Thor puts all the emphasis on readiness for an immediate retaliatory strike, no matter how heavy and cumbersome a ground installation you need to get that result. Whereas Jupiter took a leaf out of the Army's mobility book by saying, "We would like to be able to move around and change our launching sites frequently even if that requirement makes our immediate retaliatory capability a little more difficult to obtain than if we were to adopt the Thor concept." In other words, Jupiter offers mobility; we don't need any fixed bases.

Now, I think notwithstanding all the papers written on this subject, nobody can really say today which is the better approach. Nor can anyone decide today whether Jupiter or Thor has the better nose cone or the better guidance system. The only way to find out is by building both missile systems concurrently and by evaluating the performance of both.

Mr. FORD. From the point of view of the country's national security, it was wise to proceed with the research and development of both systems.

Dr. VON BRAUN. I am convinced of that.

Mr. FORD. Would you say that the same applies as far as the ICBM programs, the Atlas and the Titan?

Dr. VON BRAUN. Yes, sir. You have exactly the same situation there.

In this case both missile systems were developed right from the outset by the Air Force, and the Air Force itself has always considered it advisable and smart to develop two competitive ICBM's.

I think what is right and logical for the ICBM is just as right and logical for the IRBM.

Unfortunately, the fact that the Army originally had initiated the development of the Jupiter, whereas the Thor development was initiated by the Air Force, has thrown an element of interservice rivalry into the comparison of the two. Ever since the roles and missions assignment for the IRBM was given to the Air Force, statements have been made that the Air Force really does not need the Jupiter, that it would be happier with only one IRBM, the Thor, of course. But look at the ICBM's. They were both initiated by the Air Force and you still have two ICBM's.

Mr. FORD. In other words, if the Jupiter and the Thor had been developed by one service rather than two, it still would have been a wise decision to proceed with the research and development and the actual execution of the procurement?

Dr. VON BRAUN. I am convinced of that.

Mr. FORD. Would you say the same as far as the Polaris system is concerned?

Dr. VON BRAUN. The Polaris situation is very different. Polaris is supposed to be a submarine missile and it is quite obvious that neither the Thor nor the Jupiter lend themselves well to submarine application.

Conversely, if you tried to replace Jupiter by a missile like Polaris, and you want to move it around the countryside, you'd find its mobility rather limited, because its solid rockets cannot be loaded or fueled in the launching site like a liquid fuel rocket. So you always have to handle the fully loaded missile, and to truck such a heavy item around the countryside would be quite difficult.

The Navy, of course, need not bother about this drawback at all because they would load the Polaris missiles into the submarine in a

harbor where large harbor cranes are available, or they would reload the sub out on the ocean from a fleet tender which also would have suitable ship cranes or loading booms available for this operation.

Mr. FORD. Since early 1958 there has been set up ARPA. It has been given the right to control certain obligational authority in both the Air Force and the Army and, of course, in the budget proposal for fiscal 1959, originally as I recall it was $340 million.

In the second supplemental I think it was around $180 million, making something over $530 million or $540 million for ARPA's operation as opposed to fiscal 1959.

In your view, is there adequate funding in ARPA in fiscal 1959 for the program that you feel has priority?

Dr. VON BRAUN. Sir, to my knowledge the $500 million you just quoted for ARPA are not exclusively for an outer-space program. Much of this is earmarked for direct support of the existing ballistic missile programs and other related military programs.

I think for outer space there is no more than $250 million, something like that, maybe $300 million.

Mr. FORD. Included in the five hundred and some million dollars for ARPA, in fiscal 1959 that is, there are funds for the Nike-Zeus; are there not?

Dr. VON BRAUN As far as I know, yes, sir.

Mr. FORD. Could you tell us how your office at Huntsville works in relationship to ARPA?

Dr. VON BRAUN. ARPA is giving us task assignments for certain experimental rocket flights in the outer space area such as satellite launchings or the lunar escape flights which were previously discussed in this hearing We have a certain number of such projects assigned to the Army Ballistic Missile Agency in Huntsville from ARPA Our 1958 program is well underway.

What we badly need and quickly, is full funding for our 1959 program for ARPA because there are long lead times involved to buy rocket engines and airframes and guidance and control components to draw from, because our entire supply of these components is earmarked for our military obligations, in other words, for the Redstone and Jupiter weapons systems.

Let me be more specific here. We have assumed certain obligations toward the Air Force to supply the Strategic Air Command with a specified number of Jupiters beginning in early 1959 and following up throughout calendar year 1959. Every single Jupiter rocket engine, every Jupiter guidance system presently on order is committed to this program, and has been financed out of ballistic missiles funds.

If we are to launch satellite or moon or escape vehicles based on the Jupiter missile for ARPA during calendar year 1959, we have to buy Jupiter engines, Jupiter airframes, and Jupiter guidance components right now, no matter what the specific space missions of these rockets will be, because they all will need Jupiter engines and they all will need Jupiter guidance systems.

In this area we need more money badly. ARPA itself does not have that money at the moment.

Mr. FORD. In the fiscal 1958 availability?

Dr. VON BRAUN. I am talking about money for fiscal 1958, that must be spent now in order to buy a calendar year 1959 space capability.

Mr. FORD. Would it be your offhand comment that the establishment of ARPA was beneficial as far as the space program, related program, is concerned?

Dr. VON BRAUN. Yes, sir; very definitely.

Mr. FORD. You made the comment earlier that the Vanguard was a nonmilitary powerplant. Does it have a military capability, if needed, or one that is adapted to a military capability?

Dr. VON BRAUN. Military capability of at least certain elements of the Vanguard missile, such as the first stage, is definitely conceivable.

I am not aware of any military program envisaging the use of Vanguard hardware at this moment.

Mr. FORD. In the space program do you ever envision the use of a solid propellent in your first stage?

Dr. VON BRAUN. In the first stage?

Mr. FORD. Or in any stage?

Dr. VON BRAUN. We are using solid propellents in the upper stages in the Jupiter C when firing our Explorers.

Mr. FORD. I was thinking of the main thrust. Is solid propellent feasibile or desirable?

Dr. VON BRAUN. The general tendency for solid propellent rockets is to become available in ever larger units, but as larger and larger solid rockets are being built the thrust and burning time of liquid rockets is also going up.

As of today, when it comes to total rocket impulse (by that we mean the product of thrust times operating time) the liquid rocket still beats the solid rocket by a very large margin.

Mr. FORD. I believe that is all, Mr. Chairman.

The CHAIRMAN. Mr. Brooks, do you have some questions?

Mr. BROOKS. Doctor, I want to ask you a few questions along a little different line than what has been covered. You have been down at Redstone how long?

Dr. VON BRAUN. Since 1950.

Mr. BROOKS. You have been working all that time on missiles?

Dr. VON BRAUN. Yes, sir.

Mr. BROOKS. Now, are they principally military missiles that you are working on, or are they purely scientific programs?

Dr. VON BRAUN. Sir, our main missions have always been military missiles, the Redstone and the Jupiter and now the Pershing.

But in order to effectively pursue the development of military missile projects, you sometimes have to assign missiles for supporting research tasks.

Mr. BROOKS. That is one of the points I am getting at. In order to develop your military missiles you must apply pure science and the missiles you develop may be interrelated with peaceful uses; is that right?

Dr. VON BRAUN. Yes, sir; we have used the Redstone missile to make nose cone reentry tests for the Jupiter program and then used this very same missile also as our Explorer satellite carrier.

Mr. BROOKS. Would you say that the Jupiter was a military development, too?

Dr. VON BRAUN. The Jupiter is a military development. Jupiter C is the multistage missile based on the Redstone which was developed

for scientific support of the Jupiter development program, particularly to test nose cones.

Mr. BROOKS. So it essentially is military, too?

Dr. VON BRAUN. It was financed with military funds because it was necessary——

Mr. BROOKS. You take your orders down there from the military; do you not?

Dr. VON BRAUN. Yes, sir.

Mr. BROOKS. Are you given frequent opportunities to explore peaceful development of the missile program and the satellite program?

Dr. VON BRAUN. To the extent that ARPA sends us orders, yes, sir; these assignments utilize a limited portion of our shop and laboratory capacity.

Mr. BROOKS. You follow the orders that come from the Pentagon?

Dr. VON BRAUN. Yes, sir. Right now about 20 percent of our capacity at the Army Ballistics Missile Agency is used for the Advanced Research Project Agency (ARPA) for scientific programs whereas about 80 percent is assigned to military weapons systems.

Mr. BROOKS. Twenty percent is for science?

Dr. VON BRAUN. Yes, sir.

Mr. BROOKS. Whether it will be adaptable to military or nonmilitary purposes?

Dr. VON BRAUN. Yes, sir.

Mr. BROOKS. Now, in pushing this program on September 20 you received a stop order—September 20, 1956, you received a stop order on the Jupiter-C. That is true; is it not?

Dr. VON BRAUN. After we had fired the first Jupiter C over a range of 3,300 miles we had hoped that this would persuade the Pentagon to give us permission to try a satellite launching, but this hope never materialized.

Mr. BROOKS. If you can say without disclosing any military secrets, how high did that missile go?

Dr. VON BRAUN. 680 miles.

Mr. BROOKS. And 3,300 miles distance.

Then the next day you got a stop order to stop development; is that not true?

Dr. VON BRAUN. No, sir; we were permitted to continue to use this missile for reentry testing of our Jupiter nose cone models, but we were not permitted to make a satellite launching.

Mr. BROOKS. So you got a stop order for any development of more distance or more elevation in that missile?

Dr. VON BRAUN. Specifically we were not permitted to fire into orbit.

Mr. BROOKS. In the meantime the Russians sent up a satellite.

Now, you finally did send the Jupiter-C off into orbit after 83 days, I think you stated.

Dr. VON BRAUN. Yes, sir.

Mr. BROOKS. Could you have done that in 1956?

Dr. VON BRAUN. Yes, sir.

Mr. BROOKS. In that event we would have been 1 year ahead of the Russians in development had you been given a free opportunity, the green light as we say, to go ahead with the program?

Dr. VON BRAUN. Yes, sir.

Mr. BROOKS. We would have been a year ahead of the Russians?

Dr. VON BRAUN. Yes, sir.

Mr. BROOKS. Now, you say the Russians are ahead of us in certain developments of this missile program. It would seem to me that we were ahead of the Russians in this particular program.

Dr. VON BRAUN. Sir, a satellite launching in 1956 probably would have required a little more luck than we needed now—a year and a half later—which offered us quite a little bit more time to shake down the rocket hardware. Also, our satellite weighs only about 30 pounds, including the empty casing of the last stage.

We should not lose sight of the fact that Sputnik II weighs 1,280 pounds.

Mr. BROOKS. Is there any significance in the difference in weight of the sputnik and the Jupiter-C?

Dr. VON BRAUN. Yes, sir; it means that whereas the light Jupiter-C payload was lifted off the ground with about 80,000 pounds takeoff thrust, the Russian sputnik rocket must have had several hundred thousand pounds thrust to put that much greater payload in orbit.

Mr. BROOKS. Does that show more efficiency on the part of our rockets?

Dr. VON BRAUN. No, sir; it means, by way of comparison, that they have a large cargo aircraft at their disposal compared to which ours would look like a pigmy airplane.

Mr. BROOKS. What we need is development of more cargo-carrying capability for our missiles?

Dr. VON BRAUN. Yes, sir; and our ICBM's will have that cargo carrying capability, too, but the trouble is that they do not yet fly over the full range whereas the Russian ones do.

Mr. BROOKS. You cannot develop that out of the Jupiter C?

Dr. VON BRAUN. No, sir.

Mr. BROOKS. If we were able because of our development to have gotten ahead of the Russians by 1 full year, I want to ask you this: How you find our scientists in this country? Do they seem to compare with those that you have had any acquaintance with in Russia or Germany?

Dr. VON BRAUN. Sir, I think in this country we have all the scientists and engineers it takes to do the job.

Mr. BROOKS. Do we have the scientists over here and the scientific ability in the United States to keep up and get ahead of the Russians in this development?

Dr. VON BRAUN. Yes, sir; absolutely.

Mr. BROOKS. You do not find anything critical or wrong with the training of our scientists in general?

Dr. VON BRAUN. Sir, this is a long story in itself. I do not want to make a sweeping statement.

Mr. BROOKS. You are in a position where you can pass judgment, if you will in a general way, upon the ability of American scientists to do this type of job.

Dr. VON BRAUN. Sir, I am seriously concerned about the momentum of the Russian educational program. I feel very strongly that we should not underestimate it, but should really do something about it. This is a fateful national problem, a more serious threat, in the long run, than even satellites and ballistic missiles.

Mr. BROOKS. You feel strongly we should develop our own people to the limit of our ability to do so?

Dr. von Braun. Yes, sir

Mr. Brooks. You find nothing critical or wrong with our scientific staffs now?

Dr. von Braun. No, sir. I think we have the capability to do it, but we cannot afford to sit back and relax either.

Mr. Brooks. Now, when I was home the other day people began to say, "What is the advantage of putting a platform up in space?" Can you tell us here what is the advantage to this country of putting a platform in space and keeping it there for any extended period of time?

Dr. von Braun. I believe this famous platform in space should not be singled out as one particularly significant achievement. I think we should look upon outer space with somewhat different views.

The same goes for the often repeated question as to what extent this space business is a scientific effort, and to what extent it is a military effort.

I think most of these questions assume a new perspective when we only realize that the exploration of space has become technically possible now due to the general progress made in the art of building large missiles. This has led us into a situation which is in some respects similar to that of shipping shortly after the invention of the compass

All of a sudden it became then possible to leave the shores and cross the oceans and explore distant lands. Claims were staked out and trade routes developed, but very soon thereafter the nations sponsoring such exploration felt that they had to protect their expeditions and foreign footholds and trade lanes and this brought frigates and caravels and finally full-fledged navies into the act.

Very much in the same way I think, in the long run we cannot hope to pursue a purely scientific or economical program of exploration of outer space without a minimum amount of military backing. Let us not forget that the Spanish did not and could not only send cargo ships over to Central and South America to explore and exploit and colonize these lands, they soon found it necessary to build their armada to protect this operation.

Mr. Brooks. So the significance you attach to it is military?

Dr. von Braun. No; not all military. Exploration of new lands, whether in Central America or on the moon, should be a double-barreled approach. The scientific exploration comes first, but the military protection of it must go hand in hand with it.

Mr. Brooks. You find no peaceful approach to it, then?

Dr. von Braun. Sir, I think history is full of examples that prove that one-sided unilateral statements by any one nation on some principle such as the freedom of the seas are rather meaningless unless that nation has a navy to back up that statement in case of trouble.

I think the same can be said about our forthcoming ventures into outer space. I am all for a universally accepted rule that outer space is just as free as the open ocean, but I think unless we as a nation or the United Nations have some means to back this rule up, it would remain a very meaningless, empty statement.

The Chairman. Might I interject there?

Particularly if some other nation got there ahead of us?

Dr. VON BRAUN. If they got up there first, we may have lost a battle, but we still would not have lost the war.

Mr. BROOKS. Of course, you feel that the control of outer space means the control of the universe?

Dr. VON BRAUN. The universe is a rather big place.

Mr. BROOKS. Let us limit this to the world, this earth.

Dr. VON BRAUN. I have not the slightest doubt that the question of whether we or another nation has control of the spaces around the earth will have a very great impact on our military position on the earth itself.

In other words, space superiority, control of the spaces around the earth, will soon be just as important as air superiority is today.

The CHAIRMAN. When you edit that answer will you elaborate on that, Doctor?

Dr. VON BRAUN. I shall be glad to.

Mr. BROOKS. Why do you not let him elaborate on it now, Mr. Chairman?

The CHAIRMAN. Go right ahead.

Mr. BROOKS. Do you want to elaborate now?

Dr. VON BRAUN. Orbiting vehicles have a reconnaissance capability, for example. You can look down on lands which are not accessible by aircraft because of iron and bamboo curtains and the like. So the privacy of military preparations behind such curtains will cease to exist with the advent of the reconnaissance satellite. That works both ways, of course. A Russian reconnaissance satellite can likewise look down on our SAC bases and our naval ports. Any secret military preparations anywhere in the world will become very quickly impossible

Mr. BROOKS. We can look down on their atomic-energy program, too?

Dr. VON BRAUN. Yes, sir.

Mr. BROOKS. There is one more thing I want to develop and then I am through. I want to ask you this:

You have said a lot about outer space. I have heard the military refer to it as different elevations. Normally in your work in outer space what elevation would you place? Would you say 60,000 feet above the earth, above that would be outer space?

Dr. VON BRAUN. I think 60,000 feet is still a happy hunting ground of the present-day Air Force.

Mr. BROOKS. You would figure above 60,000 feet would be outer space?

Dr. VON BRAUN. I would say outer space begins above 100 miles.

Mr. BROOKS. Below 100 miles is inner space?

Dr. VON BRAUN. Yes, sir.

Mr. BROOKS. Thank you very much, Doctor.

The CHAIRMAN. Mr. Hays, do you mind if I ask a few questions? I have to go over and take the Chair.

Mr. HAYS. Certainly.

The CHAIRMAN. Doctor, coming to the immediate problem that concerns me, you have indicated that the Soviet Union is ahead of us in the field of ballistic missiles; is that correct?

Dr. VON BRAUN. Yes, sir.

The CHAIRMAN. That means both intermediate and intercontinental?

Dr. VON BRAUN. Yes, sir.

The CHAIRMAN. Would you care to express an opinion as to how far you think they are ahead of us in the field of intermediate missiles, in point of time?

Dr. VON BRAUN. It looks like they have an operational capability in this area right now, whereas we don't.

The CHAIRMAN. How far would you say in the field of intercontinental ballistic missiles?

Dr. VON BRAUN. They have tested theirs successfully over the full range, where we don't.

The CHAIRMAN. The fact of their last satellite would indicate they have a propulsion power for a considerable distance for intercontinental ballistic missiles, of course, with certain perfections and so forth. I am talking now about propulsion.

Dr. VON BRAUN. Yes, sir.

The CHAIRMAN. How far would you say they can shoot their intercontinental ballistic missiles? Five thousand miles? Fifty five hundred miles, or six thousand miles?

I am not saying they have perfected it.

Dr. VON BRAUN. I do not know whether I can answer this in open session. This may be classified information.

The CHAIRMAN. It is very important that we always have a retaliatory power, is it not?

Dr. VON BRAUN. Yes, sir.

The CHAIRMAN We would be in a position where they can hit us and we cannot hit them. That is vitally important, is it not?

Dr. VON BRAUN. Yes, sir.

The CHAIRMAN. The probabilities are if we ever got in that position they would not let us catch up with them. Is that a fair statement to make?

Dr. VON BRAUN. Yes, sir; it would certainly put us in a very difficult situation and subject us to all kinds of blackmail.

The CHAIRMAN. So the field we are looking into in your opinion is a very important field, the inquiries that are being made now in this hearing?

Dr. VON BRAUN. Yes, sir.

The CHAIRMAN. From a nonmilitary angle why is information concerning the outer space important? What tactical use can be made of such information from a nonmilitary angle?

Dr. VON BRAUN. Sir, I think the whole idea of exploration of space began with the same motives that have always triggered scientific progress. People are just curious and want to pursue certain new promising lines of scientific exploration. What follows in the wake of their discoveries is something for the next generation to worry about. I think it has always been that way

The CHAIRMAN. While our immediate problem might be on the military level because of the law of self-preservation, nevertheless, is it fair to say and is it your opinion that, from a long-range angle, projecting your mind as far as you can as to the uses that can be made of outer space, and we know that many more might come later—you gentlemen certainly are pioneering—would there be a great advantage to the people of the world from a peaceful angle?

Dr. VON BRAUN. Sir, I believe the very idea of extending our field of activity—I am talking of mankind as a whole now—of extending our sphere of operations and activity beyond our own planet, the very scope of this idea holds so many possibilities that it is very difficult to exactly predict what will follow.

But I think it does not take much imagination to see that the impact of such a venture on mankind as a whole and on our civilization in particular, will be comparable to the discovery of America.

The CHAIRMAN. And particularly in the peaceful nations it will be of vital importance.

Dr. VON BRAUN. Yes, sir.

The CHAIRMAN. If you can elaborate on any question you are asked, it will be beneficial to us.

Do we have the equipment now to send an information gathering rocket today to the moon? Do you have the information? I am not talking about the facilities.

Dr. VON BRAUN. Sir, I mentioned the difficulty of hitting the moon, but if you have in mind shooting past the moon, the answer is yes.

The CHAIRMAN. Is mere weight of a satellite of importance in establishing a lead over a competitor?

Dr. VON BRAUN. Satellite weight is an indication of the progress attained in rocketry. From a scientific point of view more weight in orbit enables you to conduct all kinds of space research that would be denied to a competitor with a less powerful carrier rocket.

For example, we could not have launched a dog into orbit yet with the missiles we had.

The CHAIRMAN. What is the heaviest satellite we can place in orbit with our presently available rockets, if you can answer that?

Dr. VON BRAUN. I can say this much: if we use our basic IRBM carriers, Jupiters or Thors, as first stages, we could orbit payloads in the order of several hundred pounds. If we use ICBM's, once they are a little bit further along the road, we can orbit payloads of well over a thousand pounds, several thousand pounds.

The CHAIRMAN. To explore and learn about the moon, is it necessary that a man be sent to that planet?

Dr. VON BRAUN. I think it is not necessary on the first try. In fact, it is most unlikely that on the first try a man will go along. But I think it is equally unlikely, after equipment has been successfully landed on the moon so that we can obtain information radioed back from the surface of the moon, that man can be held back much longer from going there and seeing for himself.

The CHAIRMAN. I have three more questions. I will just ask them and I am asking each one of you gentlemen, in looking over the testimony, or editing as we call it, to then consider them and answer them.

(1) What commercial utility do you foresee for long-range, point-to-point rockets?

(2) What commercial utility do you foresee for orbiting satellites?

(3) What military utility do you foresee for orbiting satellites?

There is no need of answering now because I realize that requires some consideration and thought. I know you can given an extemporaneous answer, but I would rather you gave a prepared answer because these hearings will be printed.

(Material referred to is as follows:)

Following are answers to questions posed by chairman of House Select Committee on Astronautics and Space Exploration to Dr. von Braun.

Question 1. What commercial utility do you foresee for long-range point-to-point rockets?

Answer Reusable rockets carrying high priority cargo, including mail, over long distances to an exact location are a distinct possibility Delivery of emergency items to out-of-the-way locations can be handled expediently by rocket. Also, the time is not too far off when man himself will be transported quickly and safely over great distances by rocket.

Question 2 What commercial utility do you foresee for orbiting satellites?

Answer An orbiting satellite with appropriate electronic gear can act as a communications station for truly rapid communication with any part of the earth At an altitude of approximately 22,000 miles, 3 orbiting satellites can effectively cover sufficient portions of the earth so that television may be transmitted and received between any 2 points on the surface of the earth. Later on, as manned space flight becomes a reality, these extraterrestrial stations will serve as communication links between the space traveler and earth. Large orbital space stations will be established to accommodate the space traveler.

Question 3. What military utility do you foresee for orbiting satellites?

Answer Orbiting satellites will provide a platform for global surveillance (i. e., detection of ICBM launchings, satellites, etc), for redefining the shape of the earth and determining the exact locations of land masses, oceans, cities, etc. Transmittal of high-priority military messages could be handled without interference by a specially designed communications satellite. Large satellites will serve as logistics centers and jumpoff points for combined scientific and troop expeditions to the Moon, Mars, Venus, and beyond

As I stated in testimony before the committee, I believe that satellites can be effectively used as weapons platforms in time of war. I disagree with one of the conclusions of one of Dr. Killian's reports which makes a premise to the contrary.

(NOTE —Part of the answer to this question is classified secret)

The CHAIRMAN There may be other questions that members might want to ask to have you gentlemen consider upon reflection and to answer in editing your testimony.

The fact is that it is vitally important that we always be in a position where we are capable of deterring, and I do not like the word, through the method of retaliation. Is that correct?

Dr. VON BRAUN. Yes, sir.

The CHAIRMAN. In the immediate foreseeable future that is one basic consideration we cannot escape; is that correct?

Dr. VON BRAUN. Yes, sir.

The CHAIRMAN. Do any of you gentlemen agree with that, Dr. York and also Dr. Merkle?

Dr. YORK. Yes.

Dr. MERKLE Yes, sir

The CHAIRMAN. We would like to have you in your editing put your background in the record. While it is not necessary for us, it should be in the printed record.

I have to leave. I am acting Speaker, so you gentlemen will excuse me. I will leave the committee in charge of Congressman Brooks as acting chairman.

When you recess may I suggest that you recess until 2 o'clock.

Mr. BROOKS (presiding). Are there any further questions?

Mr. HAYS. Dr. von Braun, pursuing the question that Mr. Brooks asked you, are you getting sufficient support?

I refer to the development of new fuels, propulsion systems and new materials, more emphasis is needed in these fields.

Dr. VON BRAUN. There is much going on in these fields. I would say there are three main problem areas:

One is the development of more powerful rocket engines, engines of more thrust. This development is based on conventional methods, and conventional fuels. It is, in essence, a scaling-up of a proven technology.

Secondly, there is the development of rocket engines utilizing more advanced propellents and propellent combinations, and the development of nuclear rocket engines. This is a pioneering job, in which it is a bit more difficult to pin down exact target dates for the completion of the task.

Mr. HAYS. You refer to bombing capabilities of a space vehicle. The President's Advisory Committee reports stressed that there was not a bombing capability from space. I say this for clarification.

Dr. VON BRAUN. I find myself in disagreement with the President's Advisory Committee on this point.

Mr. HAYS. You do not agree with their statement?

Dr. VON BRAUN. No, sir, I do not agree on this particular point.

Mr. HAYS. I have seen public statements that the Russians sputnik rocket had a thrust of several hundred thousand, or a million pounds.

Question No. 2 in that case, the case of Sputnik No. 2, the statement has been made that it was heavier than the Russians indicated; is that correct.

Dr. VON BRAUN All I know about that is what I just read in the papers, myself, sir. I am in no position to comment on that question at this moment.

The much greater weight now credited to Sputnik No. 2 seems to be a conclusion by the Smithsonian satellite tracking group. In analyzing the gradual decay of its orbit this group apparently found that Sputnik No. 2 stayed aloft longer than they had predicted on the basis of the 1,280 pounds weight which the Russians had mentioned.

So they suggested that Sputnik No 2 may have been heavier than the weight given by the Russians. How sound that conclusion is, I am in no position to say.

Mr. HAYS. It would be difficult under present circumstances to shed much light on that, I suppose. I suppose that would be difficult under present circumstances for us to determine with accuracy?

Dr. VON BRAUN. Yes, sir.

Mr. HAYS. Thank you, Mr. Chairman.

Mr. MCDONOUGH. Have we obtained more scientific information from our satellites? Are they better equipped than those the Russians up to now have put into orbit?

Dr. VON BRAUN. Sir, the Russians have not published the results from their sputniks yet. Under the agreement between the nations participating in the International Geophysical Year all participants are to supply the world with the results of their satellite firings 8 months after the firing itself.

Even for Sputnik I, these 8 months have not elapsed yet. But there are indications that the Russians will publish a report on both sputniks.

Only after studying these reports will we be in a position to say what they really learned. Of course, they may not tell us the whole story, but only part of it.

Mr. MCDONOUGH. How much pertinent information have we obtained from the satellites that we have placed in orbit?

25973—58——4

Dr. von Braun. I can speak only for our two Explorer satellites. Both have been very successful. They have actually supplied us with all the information that they were designed to furnish.

Explorer No. III in particular, which at first did not look so good, turns out to be a real bonanza so far as scientific information is concerned.

The very fact that it has an unusually high spread between lowest altitude and highest altitude, gives us much more information than we had originally hoped for.

In addition to this, Explorer III is equipped with a tape recorder which records cosmic-ray information during the entire orbital flight around the earth. This tape is played back (upon the receipt of a coded signal from a ground) to whatever receiver station just happens to be underneath the satellite. To "interrogate" Explorer III, this station transmits the playback command to the satellite.

In this fashion we get approximately 100 times more information out of Explorer III than we got from Explorer I.

Mr. McDonough. And you continue to get it?

Dr. von Braun. We continue to get it. The cosmic ray people involved in the Explorer III experiment have made some discoveries that were quite unexpected.

Mr. McDonough. Does the fact that we shot our satellite to a greater distance away from the earth indicate that we used greater thrust in takeoff?

Dr. von Braun. No, sir. You can always trade payload capability for altitude.

In other words, the lower the orbit the more payload you can put in the nose of a given rocket, and the higher any given rocket is to go, the less payload weight it can carry. With the thrust that the Russians must have had in their Sputnik II rocket, they could certainly place several hundred pounds of payload on the moon, which we could not do with any of our flight-tested rockets.

Mr. McDonough. Now, the greatest distance we have shot a satellite from the earth is what?

Dr. von Braun. I think the highest altitude attained by any man-made object so far was reached by Project Farside of the United States Air Force. Farside was a balloon-launched, unguided, multi-stage, solid rocket. So far as I know, it lost radio contact with the ground at about 2,500 miles altitude, and the thing was still climbing at that time.

Mr. McDonough. That did not contain any scientific apparatus to give us any information?

Dr. von Braun. There was some measuring equipment in the nose, but they lost radio contact at about 2,500 miles altitude.

Mr. McDonough. That did not go into orbit, though?

Dr. von Braun. No, sir; it was not meant to.

Mr. McDonough. Does the apogee indicate that that is the most distant point when you shoot it away from the earth? When does a satellite start orbiting and at what distance and why does it go farther away after it has gotten into orbit?

Dr. von Braun. In order to orbit, an object has to go fast enough in a horizontal direction so that the centrifugal force caused by the curvature of the trajectory is strong enough to cancel the gravitational

pull of the earth. If centrifugal force and gravitational force cancel each other exactly, the result is a circular orbit.

When the object attains a somewhat higher velocity, then you get an elliptic orbit, a kind of egg-shaped orbit, and the highest point of such an elliptic orbit is called the apogee and the lowest point is called the perigee.

Mr. McDONOUGH. Is the apogee the point at which it starts to orbit when it leaves the earth?

Dr. VON BRAUN. No, sir; it orbits all the time. An elliptic orbit simply is not a perfect circular orbit, but an orbit with distinct high and low points.

Mr. BROOKS. Mr. Fulton.

Mr. FULTON. The question comes when we get beyond the means of travel we are speaking about now. What are the limits to which we can go?

For example, we are talking of speeds that are from 18,000 to 25,000 miles an hour on the orbiting phase. When we get beyond the phase of orbit, then we are talking of a different field entirely.

May we just put our minds to that for a minute. You have said, I think, as one of the classic understatements of the year, the universe is quite a big place, and that is right. The question come up what are the outer limits? We are talking of this kind of speed. We are talking of speeds that originate on the earth or in relation to the earth's timing or calendar.

Suppose we move out of that sphere into the universe, beyond gravity, beyond the atmosphere and beyond the atmosphere of any planet. Then the question comes on the maximums of speeds, on the speed of light, 186,300 miles a second.

Do you think that we on our approach to the universe, when we think of it as extending millions and tens of millions of miles, do you think we can look ahead to speeds that can approach the speed of light and if that is so, is the speed of light the limit?

Do you agree with Einstein, when you hit the speed of light you are done?

Dr. VON BRAUN The speed of light is a definite upper limit in the sense that no object can exceed it. For a body traveling at the speed of light time does not pass This means that the speed of light is the highest speed theoretically attainable.

Mr. McDONOUGH Is that attainable or conceivable?

Dr. VON BRAUN. Attainable.

Mr. FULTON. Do you agree with that?

Dr. VON BRAUN There is no argument on that point in the scientific world. It is a generally accepted fact.

Mr. FULTON. You feel that as we approach 186,300 miles per second that is approaching the highest speed attainable?

Dr. VON BRAUN. Yes, sir.

Mr. FULTON. Of course, Mr. McDonough made quite a point there, it is possible for me to think that I am going that fast and throw a baseball 20 miles an hour faster.

Dr. VON BRAUN. The time scale gets distorted as you approach the speed of light. If you travel at close to the speed of light, then time passes slower for you than for the people you left behind. So for you it still looks like the baseball is leaving you at the rate of

20 miles an hour, in the forward direction, but for the people left behind it still has not exceeded the speed of light.

Mr FULTON. Suppose I am approaching very closely the speed of light and throw a baseball ahead faster, now what would happen? I have done the impossible, at least in conception.

You see, there is a breakthrough on sound.

Dr. VON BRAUN. The inertia of mass increases also, as you approach the speed of light, and it would require an infinite amount of energy to accelerate an object beyond the speed of light.

That is why it is physically impossible to exceed the speed of light.

Mr. FULTON. That is your maximum of speed. What is your termination on distance? Where does the universe end to you? How far can we go in space?

Dr. VON BRAUN. I think for the practical purposes of astronautics and space flight it would be a good idea to limit our thinking to the solar system, at least for this and the next few generations.

Mr. FULTON. Now, we talked of the practical and we talked of the concept. You think of the universe as a wheel and we can only go so far in one direction and we find ourselves coming back.

Dr. VON BRAUN. Yes, sir; This is quite correct. But I do not believe that this is a consideration of any practical importance for space travel, simply because the travel times involved would be far in excess of the lifetime of a human being.

Mr FULTON. Yes; but if you bring the speed up to approaching the speed of light, we are talking of a very different concept.

I believe you were the one who said, "Please don't make the programs limited for military end use, keep your mind open and broaden it."

Now, when this committee shows it is pretty broad, you are the first one to say "No."

Dr. VON BRAUN. I am sorry, it may well be that five generations from now people will say I was very narrow and old fashioned in my concepts of space flight

Mr. FULTON. Should we hire another superspace scientist then?

You see, the question is where does your field end You have spoken, according to Mr. Brooks, of 60,000 feet as the beginning of space. Where is the practical area, both on speed and on distance where this committee should limit its phases?

You see, I am setting the outer reaches and, of course, we come to a point where we look at the practical against the concept.

How far should we speak of on this committee? What is the limit of our jurisdiction?

Dr. VON BRAUN. I do not see why you should set yourself a limit at all. Why don't you just say the sky is the limit, or infinity is the limit

I just do not believe that in the foreseeable future manned travel beyond the solar system will be a practical consideration because the traveling times are so long.

Even if we had power sources to travel at speeds close to the speed of light it would take about a year to build up our cruising speed without crushing the crew members by the acceleration that is necessary to build up to that speed. And this full year would be needed solely for the first departure maneuver.

Mr. FULTON. For all practical purposes then what do you set as the speeds and the space limitations on this astronautic approach or a national plan for astronautics? What is your limitation?

You see, we must set the field. Mr. Brooks very adequately pointed out the lower limits. I am now taking the upper limits and the speed limits. Where should we set the field?

Dr. VON BRAUN. You really feel you must set a limit?

Mr. FULTON. Where we are considering our abilities in this country and our scientific capabilities and likewise the expense, should we set the field?

Dr. VON BRAUN. If you desire to set a limit I would suggest you take the boundaries of the solar system, and leave it to future Congresses to amend the act if necessary.

Mr. FULTON. Would you not limit it to the planetary system?

Dr. VON BRAUN. Yes, sir.

Mr. FULTON. The moon, Venus, Mars?

Dr. VON BRAUN. I would include even the remotest planets, Uranus, Neptune, Pluto.

Mr. FULTON. Thank you very much.

Mr. BROOKS. I will say to the members of the committee it is now after noon. The committee will reconvene at 2 o'clock.

I want to call on counsel, but Mr. Ford tells me he will be at the committee at 2 o'clock.

If it is the pleasure of the committee we will hear from Mr. Ford.

Mr. FULTON. Could I furnish questions to the record for the gentlemen to answer?

Mr. BROOKS. Without objection they will be placed in the record.

(The material referred to is on file with the committee.)

Mr. FORD. Dr. von Braun, am I correct in assuming that the V–1 and V–2 rockets are the father, so to speak, of the Redstone, Jupiter-C, and your Jupiter? Am I correct in that assumption?

Dr. VON BRAUN. Well, the V–2 was the first large liquid fuel rocket that was successfully demonstrated; yes.

Mr. FORD. When in your opinion did you father the idea of a satellite using Jupiter-C or its predecessor, the Redstone, or the V–1 and V–2, when did this concept of a satellite come into being, so far as you are concerned?

Dr. VON BRAUN. I think that concept is pretty old. It was suggested in books as early as the 1920's.

Mr. FORD. When did you first feel that there was a hardware capability of getting a satellite into orbit?

Dr. VON BRAUN. We submitted the first proposal for building a satellite based on the Redstone missile in the summer of 1954.

Mr. FORD. Had there been a concept developed that could have been feasible prior to that time?

Dr. VON BRAUN. Sir, this question always comes back to what hardware was really available and suitable for the job. Many artist's conceptions of minimum satellites had been proposed in the trade journals. But our proposal in 1954 to which I was just referring, while it was very modest in scope, had the distinction that it was exclusively based on rocket hardware that was really available and proven at that time.

In this respect alone it was unique.

Mr. FORD. Based on using the Redstone hardware?

Mr. VON BRAUN. The Redstone, and also the solid rockets proposed for the top stages were available at that time.

Mr. FORD. Was this concept predicated on the hardware which at that point was actually available or practically available?

Mr. VON BRAUN. Yes, sir.

Mr. FORD. If the Redstone hardware had been available at an earlier date, would this concept have been feasible at an earlier date?

Mr. VON BRAUN. Yes, sir.

Mr. FORD. In other words, the breakthrough in the Redstone hardware was the crux of the matter so far as an operational program was concerned?

Mr. VON BRAUN. Yes, sir.

Mr. FULTON. May I have one more question?

Mr. BROOKS. I agreed to recognize one of these gentlemen on the right here.

We will now recess until 2 o'clock. Can you gentlemen all be here?

Dr. YORK. No, sir.

Mr. FELDMAN. We have Dr. York coming at a later date in any event.

Dr. YORK. I explained to Mr. Feldman this morning that I could be here this morning.

Mr. BROOKS. This committee will recess now until 2 o'clock.

(Thereupon, at 12:15 p. m., the committee was recessed, to reconvene at 2 p. m., same day).

AFTERNOON SESSION

The committee reconvened at 2 p. m., upon the expiration of the recess.

The CHAIRMAN. The Chair understands that Dr. York has an appointment about 3 o'clock or thereabouts and arrangements were made before the luncheon recess for Dr. York to testify upon the committee's reconvening.

Dr. von Braun will step aside temporarily so that we may hear Dr. York.

We are very glad to have before us another dedicated American who is playing a very important part in the troubled world of today, Dr. Herbert York, who is the chief scientist at ARPA.

Of course he has many other qualifications which he will put in the record.

We are very glad to have you with us today, Doctor.

STATEMENT OF DR. HERBERT F. YORK,[2] CHIEF SCIENTIST, ADVANCED RESEARCH PROJECTS AGENCY

Dr. YORK. Thank you sir.

I do not have any statement to make because my being here was only arranged this morning. I shall be glad to answer questions of the same type that Dr. von Braun answered or anything else that the committee wishes to put to me.

The CHAIRMAN. Have you read the bill?

[2] York, Dr. Herbert F(rank), Radiation Lab, University of California, Box 808, Livermore, Calif. Physics. Rochester, N. Y., Nov. 24, 21; m. 47, c 3. A. B , Rochester, 42, M S. 43, Ph D , California, 49. Teaching asst., Rochester, 42–43, physicist, Radiation Lab, California, 43–45, asst. prof. Physics, 51–54, Assoc. Prof , 54—, Director Livermore Lab, 54—, Mem Air Force, Sci. Advisory Board With Atomic Energy Comm, 46. Physical Soc. Atomic physics; electro-magnetic isotope separation, scattering 90 mev neutrons.

Dr. YORK. I read it a few weeks ago.

The CHAIRMAN. Have you any comments to make about it or any parts thereof?

Dr. YORK. I have a comment of a kind perhaps, and that is that insofar as the bill makes positive statements about the NASA, I think it is all fine.

It wants to strengthen the NACA in its mode of operations and so forth.

There have been statements, though, in connection with it—I am not sure that it is in this version or not—that have said that the Department of Defense should do only those things which are associated with well-defined weapons programs.

I think one of the difficulties in the past has been that the department has not done all that it might have done in connection with programs, that there was a reasonable confidence that requirements would arise, and it often waited too long in order to have a specific and well-defined requirement come up.

That, as much as anything, is the reason that we are behind the Soviet Union today in this space work and in the missile work, too.

The Soviets began the development of big rockets just because they intuitively knew that big rockets were going to be useful.

We did not begin the development of big rockets here until after the hydrogen bomb had been perfected and until we could lay down a well defined requirement.

One of the reasons that ARPA was set up—and named the Advanced Research Projects Agency—was to anticipate reasonable requirements.

For example, in the case of the million-pound engine, there is no well-defined requirement. If we were limited by law to somehow being allowed to only work on things which have well-defined and specific requirements we could not work on a million-pound engine, yet everyone agrees that is a good idea; people in the space program, people in the Department of Defense, the Johnson committee has put it as one of its 17 points and so forth.

It is the kind of thing we would go ahead on because it represents the next big step down the road. It represents progress, if you will.

But there is no well-defined requirement for one, so that I take exception to any statements that we should only work on things for which there is a well-defined requirement.

The CHAIRMAN. Without authority, too? What was your last observation?

Dr. YORK. The bill designed to establish NASA should not have language in it which says we can only work on things for which there is a well-defined requirement—we in ARPA, in the Department of Defense.

The CHAIRMAN. Mr. Brooks.

Mr. BROOKS. What you really mean, Doctor, is that there should be pure scientific research as well as applied scientific research?

Dr. YORK. Yes. I would not make the distinction so much on the difference between pure and applied in this case. It is just that when reasonable men can agree that there is a logical next step, and this is a good example, a million-pound engine, one should go ahead with it and not wait until it has been analyzed to death and until every last possible person is convinced that there is something which you can call a specific requirement or well-defined requirement.

If we had adopted that attitude in the late forties, we would have these big missiles available today.

Mr. BROOKS. In reference to these larger engines why did we not proceed to develop the intercontinental ballistic missile and use that type of engine in the satellite program?

Instead, we proceeded with a smaller and more delicate engine.

Dr. YORK. Now we are doing that. Now we do have plans to apply our IRBM engines to the space program. When the ICBM engines are available we will apply those to the space program.

Mr. BROOKS. Then you will be able to use them alternately for a space program or for practical military purposes?

Dr. YORK. Yes. The developments of these engines and in fact not just the engines, but the whole rocket system, are expensive developments and they should be used for as large a variety of purposes as are decided important.

Mr. BROOKS. Do you call the intercontinental ballistic missile an outer space missile?

Dr. YORK. I would not call it an outer space missile when it is actually used as a ballistic missile. It is true, it traverses outer space, but I think it is useful to think of outer space vehicles as being those which stay up there for a little while, more than just 30 minutes, such as an ICBM does.

If you just change the programing, a two-stage ICBM could be used for launching satellites. It does not even need a third stage.

Mr. BROOKS. Of course, I think we are blazing a trail and in the mind of the public it is neither inner space nor outer space, or a space missile.

It is whatever we denominate it at this time.

Dr. YORK. Yes, sir; it is just a matter of words, really. It can be the same set of engines and guidance and so on that can be used either for a missile or space vehicle.

Mr. BROOKS. It would affect the jurisdiction of this committee considerably because were it considered a space missile, then it would come within the range of this committee.

If it is not considered a space missile, it may not come within the range.

Dr. YORK. Just as a handy working definition in our program we do not consider it a space missile, but that is a matter of our own convenience.

The CHAIRMAN. How high does an intercontinental ballistics missile go into space in its journey?

Dr. YORK. When used as a missile it goes about 600 or so miles in the air.

If you pointed it straight up and kept the same payload on it, it it would go about 3,000 or 3,500 miles.

If you take the payload off, it goes 4,000 miles.

As a missile, though, it only goes up 600 miles.

Mr. BROOKS. And it can be used alternately as a missile or satellite?

Dr. YORK. Yes, sir; I am sure it will be.

The ICBM's, I am certain, will become the backbone of our space program in the early Sixties.

Mr. BROOKS. Why did we lag behind in the development of the ICBM? Surely there was a practical reason for development of that?

Dr. YORK. I think one of the main reasons we lagged in the develop-

ment of the ICBM is that we waited to begin the development of big rockets until after it could be proved to everybody rather than just to reasonable men, that big rockets were important missiles.

I mean that in my opinion it should have been obvious in the late Forties that we should get on with this job, and that there would surely be use for one, but we did not. We waited until after the warheads had been developed. Whereas it is quite evident the Russians did it the other way around, they developed the missile, then they developed the warhead.

Mr. BROOKS. Did we take full advantage of the secrets that we obtained from the Germans in World War II?

Dr. YORK. No; if we had we would have the ICBM today.

Mr. BROOKS. So it is just negligence and failure on our part to give the program the proper punch that keeps us now from having the well-developed ICBM?

Dr. YORK. It was waiting for a well-defined specific requirement to arise that kept us from having it today.

Mr. BROOKS. In reference to our scientists, you are an American-trained scientist?

Dr. YORK. Yes, sir.

Mr. KEATING. Will you yield there for me to say he was trained in the University of Rochester originally.

Mr. FULTON. Is that in your district?

Mr. KEATING. That is right.

Mr. Chairman, will you just excuse the interruption

The CHAIRMAN That is nativistic pride.

Mr. BROOKS. We will overlook the colloquism there

But let me ask you, generally speaking, do you find in your work that scientists are short in their training or fail in some respects in the training they have received at American institutions over and above that which they should have?

Dr. YORK. I think that in some of the theoretical aspects of science they could have more than they do have. The Europeans in general, and the Russians in particular, do seem to have a heavier emphasis on certain theoretical fields than we have today

I think that when those of us who are concerned about American education make something of it, what we are talking about is not so much the question of availability of scientists and engineers in the United States and Russia today; it is when we conceive of the situation 10 years from now that it looks kind of glum.

Mr. BROOKS. What do you mean in reference to the superiority of the Russians in reference to certain types of scientific training?

Dr. YORK. I think even today at the Russian schools there is more emphasis on theoretical work, in fact on hard work in general, than there is in the American schools

Mr. BROOKS. Ours is more applied science, even in schools?

Dr. YORK. Yes; I guess you could say that.

Mr. BROOKS. That is all, Mr. Chairman.

The CHAIRMAN. Mr. O'Brien.

Mr. O'BRIEN. Dr. York, you mentioned our lag was due in part to the lack of specific well-defined requirements.

Dr. YORK. I think we should not wait for those.

Mr. O'BRIEN. I was wondering if within the terms you employed you believe there is a requirement now for a manned or unmanned space vehicle?

Dr. YORK. That falls in almost the same category perhaps as the million-pound engine. You cannot in the military sphere at least come up today and describe what you would call a well defined specific requirement for man in space. That belongs in the same category of things with a million-pound engine in my opinion.

It is something that we should get busy on and have a firm solid program to achieve a man in space because we know intuitively or we think there is a reasonable chance there will be a requirement for man in space and so let us go about it in a deliberate way rather than wait until the requirement arises and have a crash program 2 years behind the Russians.

Mr. O'BRIEN. There is not such a program now?

Dr. YORK There is the beginning of such a program and we hope to expand it considerably next year.

For example, the Air Force has a large air-space medicine program. The Navy has a small one. The Army has done some work in it.

There are quite a few studies in progress, both Government financed and also privately financed, on manned space vehicles.

There is not really an aggressive program going now, but we are in hopes there will be before too long.

Mr. O'BRIEN. I was very much impressed this morning with Dr. von Braun's suggestion that we should discontinue our unfortunate practice of supporting only such research and development that serves immediate military objectives.

I assume that he had partly in mind the scientific advances that will be very valuable in a peaceful way.

Dr. YORK. Yes; but in military, too. I think I am saying the same thing he was saying, but in somewhat different words.

I am fighting against the requirement for a well defined requirement.

Mr. O'BRIEN. I would assume that any advance, even if it were for peaceful purposes, could be used for military purposes.

Dr. YORK. Not just any advance, there certainly will be some which do not have military applications, but I am certain that there will be a great many that do.

That has been the history of science all along.

Mr. O'BRIEN. I understand the urgency of the military aspects of this problem. I know there will be great emphasis on this committee on certain peaceful uses of this knowledge.

Do you think that it will be reasonable to hope, in the light of what we know, that it might be possible one day to put a caravan vehicle of cargo in the sky over New York City and deliver it 20 minutes later in London? I have heard that statement made.

Dr. YORK. It certainly would be possible.

I am not prepared to answer the question as to whether it will be something useful, but it certainly will be possible.

Mr. O'BRIEN. In the field of communications it has been suggested that with this advanced knowledge we may be able to eliminate this great mass of wires we have that seems to stagger or fall whenever we have a series of storms.

Dr. YORK. Yes. There is quite a bit of enthusiasm among the people in the program in that particular field. The idea of using satellites as relay stations is one that we are planning in ARPA on working on quite strenuously next year.

In fact, there are all sorts of ways to do it. There are all kinds of questions to be answered. It is something we want to have some time to study first and then get an active program moving.

But that is one of the earliest places where one can hope for a practical payoff in space technology.

Of course, that has both civil and military interests.

Mr. O'BRIEN. Entirely peaceful.

As Dr. von Braun said, you would have to protect the skyways just as you had to protect the freedom of the seas. There were two other fields mentioned.

The question of scarce resources, we might arrive at a point in this planet where certain resources we need to acquire might become very scarce, it might be possible to obtain resources from other planets.

I realize that is considerably in the future.

Dr. YORK. That is very long range; yes.

Mr. O'BRIEN. Finally, genetic information; is that a strong possibility, too?

Dr. YORK. I don't know whether genetic information is quite the right word, but biologic information is. There is very much of an enigmatic question, a great teaser, whether for instance, there is life on Mars.

Personally I feel just answering that question, finding out that there was—well, I don't know; it would double what we know about biology today. We would know life had a good chance of springing up whenever there is a chance for it, which is something we still have to argue today.

If that is what you meant, I think space can have a tremendous impact biologically.

Mr. O'BRIEN. Dr. von Braun feels and you feel we need a long-range program; we cannot have this hit-and-miss business we have had sometime in the past.

I just raise these questions, thinking in terms of public support for substantial appropriations that might be necessary.

I have one last question.

Dr. von Braun said that NACA has been an advisory agency for the most part. You suggest a need for a decision-making group to set requirements. Do you not think that NACA as such would need to change its role to meet that need?

Dr. YORK. NACA would need to be changed in order to operate effectively as NASA. It has not been just solely an advisory committee for the last few years. It does not do much in the way of actually producing pieces of hardware for flight testing. It would have to acquire that capability, but NACA provides a good mechanism to build NASA on.

I prefer to think of it that way, that NACA is an existing nucleus of people on which you can now build NASA.

It is not so much as to convert NACA into NASA as to use it as a nucleus with which to proceed.

Mr. O'BRIEN. Thank you very much.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. Dr. York, as you know, in establishing a national space exploration program we have many problems to decide and solve. One matter that Dr. von Braun brought out this morning

was that here in this country we are peace-loving people and we have a tendency to become very quiet and peaceful to say the least, and we do not move forward as we should.

At this particular time, Dr. York, in your opinion, should we have a crash program or what type of program should we have to get this program on the way?

Dr. YORK. I would rather have a strong deliberate program than a crash program, a program about which I could use the identical words that Dr. von Braun used this morning.

I am more concerned about a strong and continuous program than I am about a crash program that builds up and then collapses downward again

Because in order to keep good people in an organization you have to keep the organization going steadily. Every time you build it up and then let it contract, the good people leave. Then you build it up again and you get a mixture in on top of the poor ones who have stayed; if you "breathe" a few times like that pretty soon you don't have a good organization any more.

It is continuity and deliberation that are worth something here.

Mr. NATCHER. Dr. York, are you satisfied in your own mind we are proceeding at the proper pace today?

Dr. YORK. Today we are in a transition period. We are still trying to get a good program going. I think it will sort of depend on what comes out of the Appropriations Committee and things like that.

We in ARPA are coming in with a program that is certainly substantially bigger than the program that has been going on.

It could, of course, be bigger. It is hard for me to judge what is the right size, but we certainly are planning a program that is bigger than now exists

Mr NATCHER. Dr. York, if not a crash program, should we not have a program that is speeded up considerably in order to overcome this lag we have? We all admit we are behind. So why not speed it up some?

Dr YORK. The space program per se will be speeded up. The missile program from which the vehicles will come that satisfy the space program has been on a crash basis or virtually on a crash basis now for several years

Our program in ballistic missiles, in ICBM's and IRBM's, is a good, strong program and a very large program, a program that has lots of people, lost of plans, lots of money and so on.

We are behind because we started so late and not so much because we are not working hard right now.

The CHAIRMAN. Are we making progress?

Dr YORK. We are making real progress.

Between the Air Force in its ballistic missiles division and the Army in its ABMA, there is a great deal of progress being made

I hope we are catching up in this particular field, but we are so far behind because we started so late.

Mr. NATCHER. In order to catch up, as I understand, you believe this program should be speeded up?

Dr. YORK. Yes.

The CHAIRMAN. Supposing we do not catch up, what then?

Dr. YORK. It is hard to know, I would have to be a future historian to know the consequences of that. But I would not like it, I am sure.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. Dr. York, when in your own mind were you convinced we had fallen behind Russia in space exploration and in the development of the IRBM, the ICBM, or in basic research, or in the whole field?

Dr. YORK. I don't think we are behind in basic research. We are in danger of falling behind, but I don't think we are behind in basic research, taking basic research as a whole.

In missiles, I don't remember when I first began—it is one of those things that I eased into gradually—to realize that we were behind.

I know, though, it was before the sputniks, but I don't remember how much before.

Mr. SISK. In view of many statements which have been made, and some of them are a little bit contradictory. I am rather interested in knowing how long you have been connected with the satellite program, with the IRBM and ICBM program.

Dr. YORK. I have been growing into it for about 6 years.

Mr. SISK. As I understand it you, you do not think we are behind in basic research.

Dr. YORK. Basic research, taken as a whole, meaning physics, chemistry, biology, and so on, even in the question of what it takes to make an engine, I don't think we are behind.

Where we are behind is in applying this research to missiles in space. We are behind in technology, not in basic science.

Mr. SISK. In other words, we are moving ahead in basic research and the basic sciences?

Dr. YORK. Yes.

Mr. SISK. Well along with the balance of the world, or ahead?

Dr. YORK. We are ahead with the Russians coming up fast.

Mr. SISK. You feel we are likely to apply the knowledge we have learned in actually putting vehicles into being; is that correct?

Dr. YORK. Yes.

As has been said by Dr. von Braun earlier, and many others before that, we could have begun the ICBM program many years earlier. We had the basic science, if you want to call it that, available immediately after the war. We did not use it.

Mr. SISK. Was it necessary, Dr. York, to do a lot of development to develop basic science before we were in a position actually to motivate an instrument?

Dr. YORK. We had to do a lot of development work, engineering development and technological development.

I think actually we are just concerned here with the definition of basic research which means different things to different people. We had to do development, we had to do engineering; we had to do some exploration, something in between basic research and engineering.

But the basic research was available years before we tried to use it.

Mr. SISK. The point I was driving at is that according to statements by others; in fact, General Medaris indicated that some of the research and development done by Dr. von Braun and his team from 1945 right through until, for example, their firing of the Redstone, I believe, in 1953, was necessary to the development of the program which we today are so much interested in.

I am a little bit curious. That is why I asked you when in your opinion we fell behind. There seems to be some contradiction of where we are behind and in what field.

Dr. YORK. We fell behind as soon as they started working on bigger engines than we were working on. That must have been in the late forties.

Mr. SISK. In other words, you feel we had the knowledge to build better engines, but because we did not put the money into it, that Congress did not appropriate the money——

Dr. YORK. We had the basic scientific information necessary to build the engine, build the guidance equipment and so forth. There is much more to a rocket than just propulsion which is where we seem to be putting all our emphasis today. That is just one component.

Mr. SISK. We have to have something to go with the thrust engine. In other words, the thrust engine alone would be worth nothing to us unless we had some research information, which, as I say, I was most concerned about, and it was my understanding that a great deal of this information was being developed during the years that actually led to where you are today.

Dr. YORK. Of course, today is a reflection of everything that happened in the past. The things that are new are more technological than they are basic science.

The CHAIRMAN. I have heard a lot of evidence that there is not enough emphasis on creative research.

Dr. YORK. There is not for the future, but in this particular program of building an ICBM, the information on which our ICBM's are being built was available long before the missiles were started.

The CHAIRMAN. You are confining yourself to ICBM?

Dr. YORK. To big rockets, whether it is ICBM's or space vehicles.

Now, we should be doing more basic research today than we are doing so that 5 years from now we will have still better ICBM's.

Mr. SISK. I just want to conclude, Mr. Chairman, with this one question.

The CHAIRMAN. I am not stopping you.

Mr. SISK. I appreciate that, Mr. Chairman.

The CHAIRMAN. This is a sort of family affair.

Mr. SISK. Dr. York, I realize this is repetitious in a way, but I still have not been able to get clear in my own mind, do you feel we have an opportunity to overcome the lead which Russia has in actually applying the research and development knowledge they have by 1960, by 1962, by 1965?

Assuming we proceed at an adequate pace?

Dr. YORK. I don't think we can catch up with them in the field as a whole by 1960; that is, in the rocket and space field as a whole we cannot catch up with them by 1960.

We certainly can catch up with them; the opportunity exists, it is just a matter of putting our backs to it.

Mr. SISK. I am not sure I understand everything you say. Do I understand that you say we can catch up; it is just a matter of putting our shoulder to the wheel?

Dr. YORK. The opportunity does exist. There are enough people in this country; there are enough facilities. We could catch up, but not by 1960. It is too late to catch up by 1960 now.

Mr. SISK. I feel there has been a doubt present in your mind. Do you believe that we are going to catch up?

Dr. YORK. I did not understand that to be the question. I said we could catch up. Whether we are going to or not is a matter of

decisions that are to be made here about how hard we are supposed to work on this program.

Mr. SISK. I think we are primarily interested in what we must do—I am speaking of the Congress—what must we do because I maintain we cannot afford not to catch up. We must catch up and we must surpass or in my opinion we will cease to enjoy life as we understand it.

Dr. YORK. I agree. I am anxious to catch up with them, myself.

Mr. SISK. That is the point I want to bring out, what you think we should do to catch up.

Dr. YORK. Work harder.

The CHAIRMAN. Mr. McDonough.

Mr. McDONOUGH. Dr. York, you mean if you are given the tools and the implements and the funds we can catch up with them?

Dr. YORK. We have the tools but we need the funds and the go-ahead and so forth. I mean all the technical people now. I was not speaking really for ARPA. I mean we technical people just need to go ahead with a program that is deliberate.

Mr. McDONOUGH. When you say we are not up to them, do you mean that they have the implements, the implementation, they have the facilities for putting into operation some of this basic science we are not doing?

Dr. YORK. They must. The evidence is they have a whole family of missiles right on up to the ICBM's, so they must have the facilities for doing it.

Mr. McDONOUGH. We know that?

Dr. YORK. Yes.

Mr. McDONOUGH. And in quantity, you mean?

Dr. YORK. Well, they have done the job. They must have had the facilities for doing it.

Mr. McDONOUGH. You are talking about military facilities?

Dr. YORK. Yes, except that a big rocket booster used for a satellite is not different from a big rocket booster used for a ballistic missile. It actually is a bit easier to put up a satellite than it is to build a ballistics missile.

Mr. McDONOUGH. You were speaking about whether we could discover the presence of organic or vegetable life on Mars.

Can we discover that without sending a man to the planet?

Dr. YORK. It may be possible, but I am inclined to think we cannot. We can discover a great deal else without sending a man up there. I would hope that an important part of our space program will be sending out what you might call Mars probes, these are devices that contain cameras and other kinds of sensing equipment, sending them out to Mars to see what they can see.

But finding life is probably a little too difficult for machinery. We certainly could not find out much about it, even if we could find out whether it exists, or not.

Mr. McDONOUGH. Do we have any positive knowledge of the existence of life on the moon?

Dr. YORK. No. It is extremely dubious, that is all you can say. There is certainly no positive evidence and there is a great deal of reason for believing there is none.

Mr. McDONOUGH. Insofar as Russia is in this position you speak of, do you mean to say they are in a position of initiative where they can attack us successfully, subdue us now?

Dr. YORK. That depends on many more factors than just the question of, say, one particular weapon like the ICBM. I do not think they are in a position to attack us and subdue us now. On the other hand, they are headed that way and let us not have it.

Mr. McDONOUGH. Are you familiar with the tests that we are about to make in the South Pacific on the deterring of missiles by nuclear bombs?

Dr. YORK. Yes, sir; I am familiar with it. I am fairly familiar with it.

Mr. McDONOUGH. That is an advance that so far as we are concerned is ahead of Russia, is it not?

Dr. YORK. That is our belief, that in that particular field we are ahead of Russia.

Mr. McDONOUGH. In other words, in nuclear development we are ahead of Russia?

Dr. YORK. In nuclear weapons development we are ahead of Russia.

Mr. McDONOUGH. That is all, Mr. Chairman.

Mr. FULTON. We are glad to have you here, Dr. York. I might say to you that Lincoln made a pretty good President. He, I think, was educated with slate, was he not, not the University of Rochester?

Mr. McDONOUGH. He had a good brain, too.

Mr. FULTON. Yes.

Let me ask this: What is your position with ARPA?

Dr. YORK. I am Chief Scientist with ARPA.

Mr. FULTON. You have relations with the National Advisory Committee for Aeronautics?

Dr. YORK. We have good relations with NACA which we expect will turn into NASA.

Mr. FULTON. So on your relationships there are no disputes between agencies at the present time, are there, that are holding back the development of missile programs, weaponry or nuclear research?

Dr. YORK. There are no disputes between ARPA and NASA that are holding back any research of this sort; no sir. I am anxious for it to stay that way.

Mr. FULTON. All right.

The CHAIRMAN. Is there anything else beside disputes?

Dr. YORK. Nothing that involves these two agencies. We have incidentally, been working together for some several months on the question of what a space program ought to be for next year. We are already hand in glove with NACA.

Mr. FULTON. But you have this cooperation although there are at present questions on jurisdiction which must be by give and take; is that correct?

Dr. YORK. There are some discussions that are going on now about who is going to do what, yes, but in the meantime these discussions are not interfering with getting ahead with the program because until NASA is set up we are going ahead and doing what we think needs to be done insofar as we are able to do it.

Remember, that ARPA has only a $10 million budget in 1958.

Mr. FULTON. You spoke of the million-pound engine. Does ARPA have the physical facilities as well as the scientific personnel to handle a program of that size?

Dr. YORK. ARPA per se does not have the facilities or the personnel for handling it. What ARPA would do in a case like this would be to find within the existing missile industry and missile laboratory groups the capability and then have the job done there.

ARPA would not do this job itself.

Mr. FULTON. No, but you would supervise it in your view; is that not correct?

Dr. YORK. Yes.

Mr. FULTON. How much have you had so far on funds for the development of the million-pound engine, a half million dollars?

Dr. YORK. ARPA has not had anything. The Department of Defense has been putting that kind of money into it in the form of study programs.

Mr. FULTON. How much was it?

Dr. YORK. I don't remember for sure, but it is around half a million dollars per year for a couple of years.

Mr. FULTON. What do you think then it would cost to develop a million-pound thrust engine? What is the total cost of that?

Dr. YORK. The engine alone would cost somewhere between 130 and 200 million dollars. That is for an engine involving a single thrust chamber, with a thrust of 1 million pounds in 1 chamber.

A rocket would cost 2 or 3 times that much.

Mr. FULTON. So really, to get an engine and a rocket with a million-pound thrust of the type we are talking about the present rate of expenditure of a half million dollars worth of study funds a year allocated to ARPA by the Defense Department it would take 400 years, if it cost $200 million, would it not?

Dr. YORK. That is the way the arithmetic comes out.

Mr. FULTON. That is simply for the engine, not the vehicle.

Dr. YORK. This half million dollars a year has been for study programs to determine what to do. It is now the sense of the department to go ahead on an aggressive program for the million-pound engine provided somebody does not come along and say "You can only work on things for which there is a specific well defined requirement."

Mr. FULTON. Do you not think it will take a dollar or two more immediately to help you on that program for the million-pound program?

Dr. YORK. I think 10 or 20 million dollars for the next year would be about right.

Mr. FULTON. How long at that pace would it take you then to develop this million-pound engine?

Dr. YORK. There are two approaches to a million pounds of thrust. One approach is by building a single barrel engine which then, of course, you could group in pairs to get up to 2 million or 3 million, or what you wanted. That would probably take about 5 years.

I don't think you can do very much to shorten it. There is another way and that is to take other big engines which are under development which have a lower thrust, some few hundred thousand pounds—I don't think I should say how much—and put them together in groups. That could be done faster.

It is not as good a way to do it, but if there were an emergency reason for having a million pounds of thrust, one could do it now.

Mr. FULTON. How quickly would it take if we did it in stages as you say you could combine them and do it at various levels?

Dr. YORK This is taking 3 or 4 engines and putting them side by side.

Mr. FULTON. That is what I meant. Various engines, do it this way or however you want to hang them on, but how quickly could you do it on that kind of crash program if you wanted to develop fast a million-pound engine?

Dr. YORK. If you decided that was the route you wanted to take and that is something about which there is some argument, I would suppose you could do that in 3 years, something like that.

Mr. FULTON Is there research going on in the use of thermonuclear power so that we do not have to stick with these old liquid propellents and some of the solid propellents?

Dr. YORK. There is research in nuclear power as applied to nuclear rockets. That is what I believe Dr. Merkle is going to be talking about.

There is not much in the way of application of thermonuclear energy to rockets.

Mr. FULTON. How much money have you received on nuclear studies in ARPA through the Department of Defense?

Dr. YORK. ARPA at the moment is not in that field. We may get into it, but we are not in that field now.

Mr. FULTON. Who has the supervision of it?

Dr. YORK. It has been jointly handled by the Air Force and by the Atomic Energy Commission.

Mr. FULTON. When you consider on the present missiles the amount of extra equipment they have to carry, is there any research being done to eliminate that equipment?

For example, in the first stage of the Vanguard you have the kerosene and liquid oxygen.

In the second stage you have the fuming nitric acid and UDMH. There is helium pressurization. There is propane.

So those fuels must all be carried. In addition at the top level we have the latex and the solid fuel.

The trouble is that there is so much elephant and so much equipment to carry for the little rabbit head.

Is research being done to eliminate all that extra equipment, all that extra fuel and likewise to shorten the countdown and also to strengthen the members so that we do not have to depend on all the plumbing and get these leaks?

Are they doing enough on that study?

Dr. YORK. They are doing quite a bit. I am sure more can be done and it will be done.

Mr. FULTON. At Cape Canaveral what struck me was the fuel and the amount of plumbing and the things that went into the program before the satellite orbited. It is a tremendous, tremendous amount.

My question is: First, are you studying it, and, second, how much money do you need really to put a crash program on and get over this hump?

Dr YORK. The answer to the first question is yes, we are studying it. It is being studied not only for the space program. That sort of thing you described is virtually on a crash basis because correcting

or improving all the things you mentioned are intrinsic parts of the entire missiles program, not just the space program.

Mr. FULTON. Is it not a fact that the space program so far has been going along on the basis of just getting what hardware you could out of the missile programs? Is that not a fact that the military has robbed Peter to pay Paul; if you want something for space that has no direct application, it must be taken from a program that has a direct military reason? Is that not right?

Dr. YORK. Well, the Vanguard was not done that way, but the Jupiter-C and the follow-on programs that have been authorized will be done, using military hardware.

Now, insofar as we can with the hardware that is in excess of what the military needs, in order to get things moving rapidly, and because of the fact that there are normally long lead times, lead times which neither we nor the public are willing to wait for, this hardware is coming out of what was originally assigned to the military program.

Mr. FULTON. So you need broader authority for space so that the hardware is ordered for space, and it should be done immediately because of the 2 years' lead time.

Dr. YORK. It should be done as quickly as possible; yes, sir.

Mr. FULTON. I have one other question.

I believe, Dr. Merkle, this would be along your line. One pound of uranium would do the equivalent in a powered missile of a thousand tons of coal and a thousand tons of whatever oxidation equipment you have.

Is that not right, Dr. Merkle?

Mr. MERKLE. From the point of view of energy that is approximately right; yes, sir.

Mr. FULTON. Then there is a real urgency to try to catch up with the Russians, Dr. York, on fuels? I am trying to broaden the field.

Dr. YORK. That holds true, of course, not only in the nuclear field, but in the chemical field, too. There are more fuels that are possible to use than are now being worked on.

But there, again, that is something which is now stepping up in connection with the missiles program as well as in connection with the space program.

The nuclear rocket applies primarily just as the space program.

Mr. Chairman, I wonder if I might be excused at this point.

The CHAIRMAN. The doctor is coming back on the 24th. How much longer do you have, Doctor?

Mr. KEATING. I only have one thing I would like to ask him now, if I could. It will not take over a couple of minutes.

Your position with the Advanced Research Project Agency is chief scientist?

Dr. YORK. Yes.

Mr. KEATING. By its very name, this is looking out into the future to see what we can do.

Dr. YORK. Yes, although we are very much concerned with the immediate space program because by the law ARPA is responsible for these programs for up to 1 year from last February, for all of the space programs.

So we are interested in the future, but we also are very much concerned about the immediate present.

Mr. KEATING. Your responsibility is existing and future?

Dr. York. Yes, in the future presumably for the military programs. For the present for all the programs.

Mr. Keating. Can you give us anything further about your future programs within the realms of security?

Dr. York. We right now, of course, are working with NACA on what needs to be done for the future of civil programs. We are working not just on NACA, but with every one. We are working with Dr. von Braun and his group, people from there and elswhere, trying to determine what a reasonable program for the future is, and we are trying to find out what are the immediate steps that should be taken to get that going.

Of course, as you know, we did authorize the 3 lunar probes for the Air Force and 4 vehicles for ABMA including 2 lunar probes.

There are such things coming along. In our plan there are such things as million pound engines, communication satellites, meteorological satellites, navigational aid satellites, and so forth.

The military programs, of course, are largely classified as to their nature, but they are quite expansive.

Mr. Brooks. I want to ask you this: Is there any particular law that is preventing you from moving ahead or do you have full power now to go ahead with your present researches?

Dr. York. ARPA was just established. It takes a certain amount of time to get people together and get going.

We are still trying to do that. We are moving as fast as we can on that sort of thing.

Also, in 1958, the ARPA budget was only $10 million Next year we expect to have enough so that we can get some vigorous programs going.

Mr. Ford. Dr. York, as I recall, the action which set up ARPA gave you $10 million, plus the right to handle the financing of certain funds from the three services.

These programs that had previously been financed in the area under your jurisdiction—you in turn, and your office, could handle?

Dr. York. We are picking them up as we can. For example, we will have responsibility in ARPA for the remainder of the Vanguard program.

Mr. Ford. Any limitation on funds, I believe, could be handled by transfers out of certain military accounts into the emergency fund and then transferred to ARPA?

Dr. York. We are looking into that; yes.

Mr. Ford. I think that is possible under the law and I believe there are funds in certain accounts which could be used for this period up to the end of fiscal 1958.

Mr. Fulton. But that robs the other funds in order to make these programs.

Dr. York. That is right

The Chairman. Thank you, Doctor

I can see we have only hit the surface with you. I know you will come prepared to answer some more penetrating questions on your next appearance.

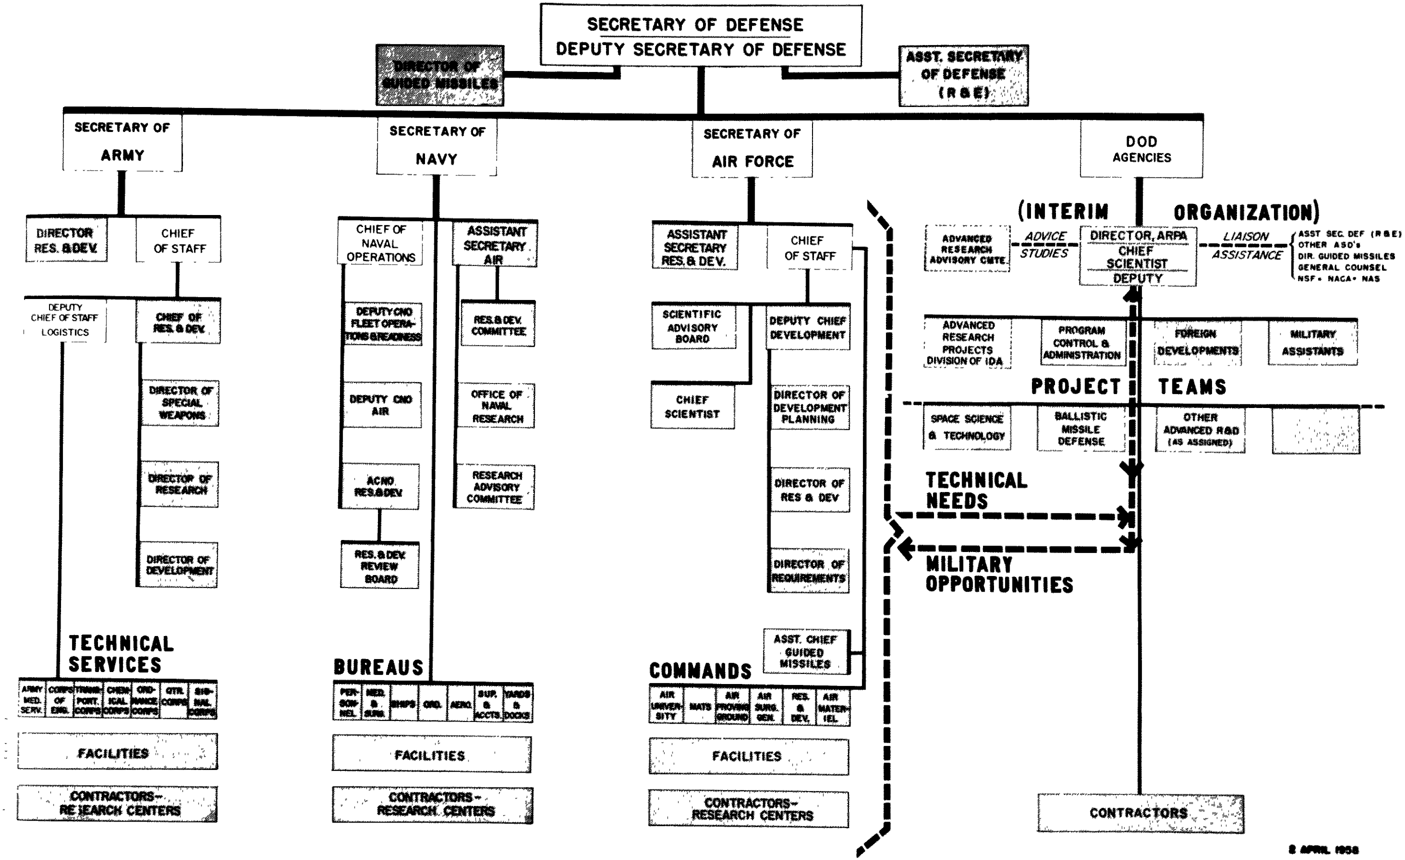
There are a lot of questions we would like to ask and get information on. Thank you, Doctor.

Dr. York. Thank you, Mr. Chairman.

(The Defense Department Research Organization Chart faces this page.)

DEPARTMENT OF DEFENSE

RESEARCH AND DEVELOPMENT ACTIVITIES



The CHAIRMAN. Are there any questions desired to be asked by the committee of Dr. von Braun now?

Mr. SISK. Mr. Chairman, I had a line of questions that I would like to pursue. Do you want me to proceed at this time?

The CHAIRMAN. You may go ahead.

STATEMENT OF DR. WERNHER von BRAUN, DIRECTOR, DEVELOPMENT OPERATIONS DIVISION, ARMY BALLISTIC MISSILES AGENCY, HUNTSVILLE, ALA.—Resumed

Mr. SISK. Dr. von Braun, I would like to refer to a little discussion we had with Dr. York. Do you agree with Dr. York that we are ahead of Russia in basic research or in general research and in what would amount to knowledge, and that primarily where we fail is in the application and actually putting into being the instruments to do the job?

Dr. VON BRAUN. Yes; I find myself in complete agreement with everything that Dr. York said here.

In particular I fully share his view that our general status of research in the natural sciences is not yet lagging behind the Russians.

There are certain fields in which the Russians have the lead, but this is solely the result of emphasis and priorities and effort that they have put behind certain projects, particularly in the missile field.

I do believe, however, that the Russian strides in the field of general and scientific education during the postwar years are so impressive that we should take a long, hard look at our own basic research efforts, to make sure that we are not falling behind in that field also.

The Russian research effort has developed a tremendous momentum, and unless we watch out there is a definite danger of our falling behind in research also.

Mr. SISK. It is your opinion that even though now and for the last few years we have been ahead in this field, unless we accentuate our own program of education, scientific development, that we can fall behind very shortly?

Dr. VON BRAUN. I would say we have been living off our capital in recent years. We are still in the fortunate position of at least not lagging behind them in the research field in general, but I think their momentum is so great that their rate of progress in this field is already exceeding ours.

Unless we put more money and effort into basic research also, we may soon fall behind in that field.

Mr. SISK. Your research work, as I understand from General Medaris, a great deal of it, was done in this country between the time you came over in 1945 right on up until you actually fired the Redstone in 1953; is that right?

Dr. VON BRAUN. Sir, I think what General Medaris meant was that between 1945 and 1951—that is from right after the war, when our German group was brought over to this country, till 1951, when we were handed the high priority Redstone project—we occupied ourselves with general missile research and with the development of certain components and techniques, which advanced the art of rocketry in general, rather than spending our time on immediate weapons projects.

I think he did not mean that all this work was absolutely vital and necessary to start a missile program in this country.

I think what he meant to say was that during those 6 years we were not sitting on our hands; we were doing something worthwhile. But there can be no doubt that we could have done more.

Mr. SISK. I agree with you. The point I was trying to bring out was that apparently the fact that you and your team and apparently others, were doing actual research work is one of the reasons why today we are still not behind. Therefore, it was important to the development of a satellite program as well as, of course, the IRBM and the ICBM with its military applications.

Dr. VON BRAUN. Yes, sir; I think the work performed at that time was quite essential. But with more money and more support more could have been done by the same experienced missile personnel.

Mr. SISK. That is certainly correct.

Of course, the thing was at that time, you were not aware you were falling behind, until at least 1955, even in the application as far as machinery and the hardware is concerned.

Now, I would like to ask you: At Redstone you operate as an arsenal. You more or less do your own development and research work and so on; is that not correct?

Dr. VON BRAUN. Yes, sir. We have an integrated facility at ABMA in the sense that we have our own design office, our own shops, our own guidance and control laboratories, our own static test stands, all operated on the Government payroll.

In addition to our in-house operations we work with a great number of contractors and our accounting shows that well over one-half of the money that goes to ABMA is actually spent in industry.

Mr. SISK. In the development of Thor, for example, and some of the other vehicles, which are to be used, is the service itself or the Air Force or the Navy actually operating on the same basis; is it all being contracted out?

I am trying to get a comparison as to which way will be preferable. Is there a drawback, for example, to the Air Force's position in times past where there is no research, or no work on their own, but they contract it all out?

I am trying to get a comparison between what you have done in Redstone with what has been done in other places.

Dr. VON BRAUN. The Air Force does not have arsenals; it has always contracted all of its development and procurement jobs solely in industry.

The reason behind this is very simple. The aircraft industry has civilian customers in addition to their main customer, the Air Force. They sell their airplanes to commercial airlines, both United States and foreign, and also to private customers.

In most fields of Army weaponry, however, there is no civilian market. There is no civilian customer for an item like a machinegun or a tank. So the Army, historically, had to build up Government-operated arsenals to have these kinds of things developed.

With the Navy the situation is very much the same. The Navy has quite a number of Navy-operated shipyards, to which special tasks are assigned that a normal private shipyard is not prepared to handle.

Now, due to the ever-increasing complexity of weapons systems, things have become a little bit involved for the Air Force, too, and

I think their missile program is a pretty good example of what I am talking about.

In complicated new weapons projects you can no longer simply go out and contract all your components without having a group of scientists and engineers sitting in the driver's seat and coordinating the overall effort, coordinating the weapons system as a whole.

In order to do that, the Air Force has availed itself for its ballistic missile program of the services of a private corporation which does essentially the same project coordinating job which is part of what we are doing at ABMA, only they do it under contract.

The Air Force contract I am referring to has been awarded to the Ramo-Wooldridge Corp. It specifically excludes Ramo-Wooldridge from building any missile hardware because their main job is to coordinate the overall program and to advise the Air Force, as to who is the most promising bidder for a certain component.

So the Air Force has found it necessary, too, to create a kind of in-house systems coordination capability in order to handle these vary complicated weapons systems. There is very little difference left between this system and the Army's arsenal concept.

Mr. SISK. Doctor, I appreciate your statement very much because that is the point I was trying to reach. We are all interested in seeing private industry do as much of this job as possible, yet in the interest of time and in the interest of moving ahead in a satellite program and in the exploration phase, I gather from what you say that it is necessary to have a nuclear scientist or have a certain arsenal-type operation rather than simply contracting out or simply asking a particular corporation to work out and build up a certain instrument.

There is one further question I would like to ask you. In view of the fact there has been more than one instance where the Army was stopped in its program, at least in an attempt to put a satellite into orbit, for example, Orbiter, the Army was working on in 1955, do you feel there was any bearing whatsoever on that due to the fact you were operating as an arsenal rather than contracting your work all out?

Dr. VON BRAUN. I do not believe that in the particular case of our satellite situation we have been affected by such considerations. The Department of Defense in 1955 appointed a committee to evaluate three independent proposals on how to build a satellite. These proposals had been submitted by the Air Force, the Army, and the Navy. The Navy proposal was finally picked, mainly because it promised to carry the largest payload with the smallest and lightest rocket vehicle.

The Navy proposal required, of course, the development of a brand new three-stage rocket, now known as the Vanguard missile, whereas our proposal was based essentially on a combination of existing and available rocketry.

Mr. SISK. Did you agree with that decision, Dr. von Braun?

Dr. VON BRAUN. I think the decision was a good one from the point of view of getting an advanced satellite rocket, namely, the Vanguard, started. It was a very risky decision in 1955 because it meant that something had to be done within 2 years that had never been done before in 2 years. The fact that a few weeks ago the Vanguard missile has successfully placed a payload in orbit indicates that the Vanguard has been developed by a very capable team.

I frankly admit they exceeded my expectations. I never thought they would make it on time.

Mr. SISK. Hindsight is always better than foresight, but you had a vehicle at that time which had been rather well tested and on which there had been a lot of research.

Frankly, I and many other people have been a little bit concerned as to why a wholly new vehicle was selected at this time in preference to a tested and tried vehicle. There is no criticism of people who made the decision.

Dr. VON BRAUN. I believe if they had told us back in 1955 that we would have to fire a satellite only in January 1958, we may have come up with a more sophisticated proposal ourselves.

As I told you, we could have fired a Jupiter-C in orbit as early as fall 1956.

Mr. SISK. That is my understanding. You feel you could have put a satellite in orbit in 1956?

Dr. VON BRAUN. We successfully fired this very same Jupiter-C missile in September 1956 and I think with this firing we proved that it could have been fired into an orbit as well.

Mr. SISK. Is it a fact that at the time there was so much pressure to be certain you did not put that instrument in orbit that people came down to see to it that certain parts of it were not activated; is that correct?

Dr. VON BRAUN. Yes, sir.

Mr. SISK. That is all, Mr. Chairman.

The CHAIRMAN. Doctor, in the bill it says:

(2) Subject to the civil-service laws, to select, appoint, employ, and, subject to such regulations as the President may prescribe and without regard to the Classification Act of 1949, as amended (5 U. S. C. 1072, et seq.), and the Federal Employees Pay Act of 1945, as amended (5 U. S. C. 901, et seq), fix and adjust as nearly as consistent with the public interest and on the basis of equal pay for equal work at rates which are reasonably comparable with prevailing rates paid by non-Federal employers for similar work, compensation of such officers and employees as may be necessary to carry out the provisions of this act;

Do you have that same provision of law in relation to those associated with you?

Dr. VON BRAUN. Yes, sir; I have it in front of me.

The CHAIRMAN. In other words, those in the field of science may be employed without regard to the Classification Act of 1949?

The reason I ask is to find out whether the provision of this bill if enacted into law would in that respect cause repercussions in other directions where professional men could not be paid under similar conditions.

In other words, this is a relative matter. I want to explore it.

Dr. VON BRAUN. Sir, I believe one of the most serious difficulties in handling large weapons systems development contracts or other research and development projects for the Government is this:

Here is, shall we say, a million dollars that we want to spend wisely on some advanced research or development project—no matter whether it is in the field of rocketry or space or radar or anything.

How can you spend it wisely? You need people with judgment who can decide what the Government ought to have. For the Government, in order to avail itself of the services of such people, it is a good idea to retain about 10 percent of that million dollars, say

$100,000, for the purpose of providing the talent and the capability of determining how to spend the remainder; namely, the $900,000.

In recent years it has become increasingly difficult to determine what is a sound and promising technical proposal. In order to evaluate the many proposals that the Government receives from industry, and in order to decide which is best from the taxpayers' point of view and to whom the contract should go, you need talent and experience on the Government payroll, too.

The Government has been chronically suffering from lack of real topnotch talent on the Government payroll, because once a man is so experienced that he can evaluate a series of weapons systems proposals, he can make many times as much money working in industry and preparing proposals for the Government rather than by sitting there behind a Government desk evaluating such bids.

I think this is a very fundamental and serious problem for the Government. If you want to cut waste, there simply must be more talent, more experienced talent on the Government payroll to decide where the tax dollar should go.

The CHAIRMAN. I was not questioning this. I wanted to inquire whether you had the same authority.

Dr. VON BRAUN. To hire people outside the civil-service pay structure? No, sir; we have not.

The CHAIRMAN. Could you go out and employ a scientist without regard to the Classification Act?

Dr. VON BRAUN. No, all our personnel are on the civil-service payroll.

The CHAIRMAN. What effect will it have upon those associated with you to know that this agency is paying more for scientists than you can pay?

Dr. VON BRAUN. Industry is also paying more than we can offer. We are used to the temptation.

The CHAIRMAN. I can see where men are dedicated. I realize that. But I can see where a man who is a scientist associated with you and, say, getting $15,000 a year—where that is the limit—we just pick that out of the air—and where another scientist working for this new agency is getting $20,000 a year, he might say, why this differential?

Dr. VON BRAUN. Well, sir, my personal opinion is that this problem of salaries for scientific personnel which has come into focus here in connection with the new space agency is a very widespread problem throughout the Government services.

The CHAIRMAN. I meant to ask Dr. York, but I will ask him later about what the situation is in his agency in relation to those with specialized qualifications.

Now, are you familiar with the letter sent by Dr. Frederick L. Hovde, Chairman of the Scientific Advisory Panel, to Secretary Brucker on October 30, 1957?

Dr. VON BRAUN. I am not certain, sir, that I know this particular document.

The CHAIRMAN. That is public. There is nothing classified about that because I ascertained that. This letter was the unanimous report of the panel, consisting of between 55 and 60 outstanding members. It says they went into the whole situation as they saw it.

Among other things, they said

The problem before the Nation is not simply one of money, facilities, nor even men—these we have in substantial amounts and that which we don't have can be provided.

Whatever the failures may be, they are primarily those of management—in which we have a share—which result in delays in decision-making and confusion in the direction of our technological forces.

Have you any observation to make on that?

Dr. VON BRAUN. I think that statement makes a lot of sense.

The CHAIRMAN (reading):

Despite rapidly developing pressures for immediate reorganization, a thorough diagnosis of our management ills must be made before remedies are prescribed.

We believe the Army's position in such a reassessment must be clear, unequivocal, and stated in terms that both our leaders and our citizens can understand and support.

The objectives can be stated—there are major deficiencies in our research and development management system which must be eliminated without destroying the entire structure.

The Army Scientific Advisory Panel recommends unanimously that the Department of the Army support proposals and actions which will produce the following results with respect to the management of science and technology for national defense:

I. (a) A redefinition and clarification of individual roles and missions of the services in areas where this is possible in the light of present and predictable conditions

(b) Freedom and authority for each service to carry out research and development effort necessary to discharge its obligations as delegated in its individual mission.

(c) A clear-cut recognition and definition of national missions which require the support of two or more services—continental air defense is an example.

(d) An effective mechanism for directing research and development effort to support these national missions.

II. Recognition and understanding at the highest Government levels of the real impact, significance, and meaning of science and technology to national defense, with continual review.

III. Improvement, through reexamination, definition, and organization, of the management procedure of decision making throughout the whole structure of national defense:

(a) To avoid present confusions concerning authority and responsibility.

(b) To support projects at optimum rates and reduce time lag between the conception and use of new weapons.

(c) To permit decisions early in the development stage, thereby stopping expenditure of money, man, and facilities when further investments will result in marginal improvements or obsolete weapons

(d) To eliminate that duplication of effort which leads to inefficient use of time, money, and manpower, retaining the advantages that accrue from multiple approach to high priority development programs in their early stages of evolution.

IV. Technological superiority cannot be secured nor long maintained unless the source from which all our future scientific strength comes is nourished and encouraged—namely, national progress in basic research and the advanced education of those of our talented young people who can become the scientists and engineers of the future.

Neither the Army nor the other services will be able to discharge their future responsibilities for national defense if means are not found, by the Department of Defense or other agencies, to support a more substantial effort in fundamental research and in training of the qualified students.

The Army Scientific Advisory Panel believes these objectives are sound and attainable, and all members of the panel stand ready to assist you in achieving them.

Had you seen that before?

Dr. VON BRAUN. I had not seen it before, but I am familiar with the general tenor of this paper, because we have very much the same complaints. For example, we have been complaining for years that

we have too little general research money at our disposal, compared with the very sizable amounts of money we get for weapons systems development. There has never been enough noney to just advance the art as such and to make progress in fundamentals.

The CHAIRMAN. The important thing is, whatever the failures may be, they are primarily those of management. That means top-level decision and authority to carry it out.

Has your experience been along that line?

Dr. VON BRAUN. I can only say that we don't get enough research money. Whose fault it is I don't know, but we have been asking for this kind of money that we can use for supporting research—without any further strings attached—we have been asking for it for years. But for some mysterious reasons this kind of money is very hard to come by, although the figures involved are very small compared with those involved in the development of a well-specified new weapons system.

The CHAIRMAN. Without objection, I will put this letter in the record.

(Letter referred to follows:)

DEPARTMENT OF THE ARMY,
RESEARCH AND DEVELOPMENT,
ARMY SCIENTIFIC ADVISORY PANEL,
Washington, D. C., October 30, 1957.

Hon. WILBER M. BRUCKER,
Secretary of the Army, Washington, D. C.

MY DEAR MR. SECRETARY: At this time, when military implications of science are so much in the public mind, you may have special opportunity to express the Army's views about reassessment of our national defense research and development program. As an aid in formulating those views, your Scientific Advisory Panel offers the following discussion.

The application of science to warfare has reached the stage where the principal guaranty of national security in the years ahead is the maintenance of scientific and technological superiority.

Revision of the management and operating structure of our research and development effort should be accomplished through careful analytical assessment on the part of our leaders and representatives with the objective of eliminating that which experience has taught us is inefficient, slow, and wasteful in our present system. Hysterical action or overhasty reorganization may result in confusion and real injury to that which is already good and productive in our existing defense system.

The problem before the Nation is not simply one of money, facilities, nor even men—these we have in substantial amounts and that which we don't have can be provided.

Whatever the failures may be, they are primarily those of management—in which we have a share—which result in delays in decisionmaking and confusion in the direction of our technological forces Despite rapidly developing pressures for immediate reorganization, a thorough diagnosis of our management ills must be made before remedies are prescribed.

We believe the Army's position in such a reassessment must be clear, unequivocal, and stated in terms that both our leaders and our citizens can understand and support.

The objectives can be stated: There are major deficiencies in our research and development management system which must be eliminated without destroying the entire structure.

The Army scientific advisory panel recommends unanimously that the Department of the Army support proposals and actions which will produce the following results with respect to the management of science and technology for national defense:

I. (a) A redefinition and clarification of individual roles and missions of the services in areas where this is possible in the light of present and predictable conditions.

(b) Freedom and authority for each service to carry out research and development effort necessary to discharge its obligations as delegated in its individual mission.

(c) A clear-cut recognition and definition of national missions which require the support of two or more services—continental air defense is an example.

(d) An effective mechanism for directing research and development effort to support these national missions.

II. Recognition and understanding at the highest Government levels of the real impact, significance, and meaning of science and technology to national defense, with continual review.

III. Improvement, through reexamination, definition, and organization, of the management procedure of decisionmaking throughout the whole structure of national defense:

(a) To avoid present confusions concerning authority and responsibility.

(b) To support projects at optimum rates and reduce time lag between the conception and use of new weapons.

(c) To permit decisions early in the development stage, thereby stopping expenditure of money, manpower, and facilities when further investments will result in marginal improvements or obsolete weapons.

(d) To eliminate that duplication of effort which leads to inefficient use of time, money, and manpower, retaining the advantages thar accrue from multiple approach to high priority development programs in their early stages of evolution.

IV. Technological superiority cannot be secured nor long maintained unless the source from which all our future scientific strength comes is nourished and encouraged, namely, national progress in basic research and the advanced education of those of our talented young people who can become the scientists and engineers of the future.

Neither the Army nor the other services will be able to discharge their future responsibilities for national defense if means are not found, by the Department of Defense or other agencies, to support a more substantial effort in fundamental research and in the training of qualified students.

The Army scientific advisory panel believes these objectives are sound and attainable, and all members of the panel stand ready to assist you in achieving them.

Yours respectfully,

FREDERICK L. HOVDE,
Chairman, Army Scientific Advisory Panel.

Mr. FULTON. Actually, on that particular point of the availability of the scientific resources of this country, we have talent available now in the guided missile or satellite and research fields which is not being used because the people are unemployed, or the program, such as the Navaho program of North American, has been canceled by the Government.

What percentage would you say of our crew of scientific talent in this field in the United States is at present unused?

Dr. VON BRAUN. I would say, in the guided missile field, at least 30 percent of our topnotch talent is not effectively used.

Mr. FULTON. Then if you take into consideration those who are running around as scientific salesmen in cars, trying to sell scientific programs, which is certainly a misuse of their talents, how many more percent would you say is being misused?

Dr. VON BRAUN. I would say these two things are very closely interwoven. The pattern usually is this: It is unavoidable that there is a certain amount of continuous reorientation in military programs. The Navaho is a pretty good example.

When the Navaho program (which is a supersonic, ram jet, long-range missile) was originally started in about 1950, it was a fine and progressive missile program. But since it took too long to develop, by today's standard, the Navaho would be obsolete. The antiaircraft missiles have caught up with this cruising type of long-range missile

and to continue its still uncompleted development would only lead to an obsolete weapon.

Mr. FULTON. Actually, are we not behind Russia in the utilization of our scientific manpower? They do not waste it like we do, do they?

Dr. VON BRAUN. What I am driving at is that there are unavoidable reorientations and outright cancellations in the missile development business. Now, every time you have such a cancellation you throw a sizeable engineering force out of work. When the Navaho was canceled, there were several thousand experienced missile people who suddenly had nothing to do. Of course, the employer will always try to keep them on the company payroll, at least the top talent and the most experienced scientists and engineers and skilled technicians, in order to be able to take on another project.

Then, in order to get that other project, it is standard operating procedure that large teams of brilliant scientists and engineers are sent out to hit the road and go to Washington and try to get a new missile project from the Pentagon.

Mr. FULTON. That is a waste of manpower?

Dr. VON BRAUN. Yes, sir; a tremendous waste of our best talent in the missile field.

Mr. BROOKS. I would like to ask you this, Doctor.

What in your experience in reference to the results obtained in doing the work yourself, and using the method of farming out, of contracting out a project?

Do you find it preferable, do you get the same results or better results by doing the work actually at Redstone or by contracting out a project; for instance, the development of an engine?

Dr. VON BRAUN. We do things inhouse, whenever there is a need for a quick improvised solution and where results are needed fast, where we cannot wait to evaluate lots of contractors' proposals and so forth. But our philosophy is to do inhouse as little as possible and to contract out what we can just as well get from a contractor. In our experience this combined arsenal-industry method is the quickest way of getting results.

Mr. BROOKS. You find that either one is effective if you do it with discretion?

Dr. VON BRAUN. Yes, sir.

Mr. BROOKS. Is that the point?

Dr. VON BRAUN. We could not possibly handle everything in-house, but I think if we depended exclusively on contractors and proposals we get from the outside, our progress would be much slower.

Mr. KEATING. On that point, may I inquire?

At the present time, do you feel that the division of responsibility between private contractors and your own, what you call in-house, is satisfactory; or are there changes which you feel should be made?

Dr. VON BRAUN. I have the impression that our contractors are quite satisfied with the arrangement.

Mr. KEATING. Are you satisfied?

Dr. VON BRAUN. We are very satisfied. If you would call these contractors in and ask them to testify on how they feel about it——

Mr. KEATING. I was thinking of it from the point of view of the Government, whether you, as a responsible person in charge of a certain division of this work, were properly satisfied about that present

division or responsibility or whether you thought some changes should be made?

Dr. VON BRAUN. No, sir; we are satisfied and we have every reason to believe that our contractors are also satisfied.

Mr. KEATING. Now let me ask you a question.

I have been concerned, as has the chairman apparently, by the provisions to which he referred about employing top personnel in this space agency. If we were to enact legislation allowing the space agency to pay any amount they thought best to professional people and you in your development were not given similar authority, would that not prejudice you in keeping your personnel or getting new personnel in your area of activity?

Dr. VON BRAUN. As I said before, we are used to being exposed to this salary differential with the industry already. By putting the space agency outside of the civil service pay structure you would just add one more outside agency to the list of industrial corporations that are paying higher salaries than the Army Ballistic Missile Agency. As bad and difficult as our position is in this salary area, I feel this one additional hurdle would not upset the applecart either.

Mr. KEATING. Do you not think there is a distinction between private industry having that capability—and there is no way that we in Government can completely meet that problem—and giving that authority to another governmental agency?

In other words, there are scientists who get something other than what they earn—I am sure you are a prime example of that—who get a thrill out of working for the Government and are not attracted oftentimes by a very much larger offer from industry. But if this existed, would this not be a more serious threat to the people working in your area than the industry threat? I do not know.

Dr. VON BRAUN. I think in the long run the Government is faced with this salary problem for scientific personnel in other areas, also.

Mr. KEATING. In your area, also, and perhaps others?

Dr. VON BRAUN. I mean it has come into focus in this particular case, but that problem exists in many other areas.

Mr. KEATING. I share that view.

The CHAIRMAN. What salary do you get, Doctor, in your responsible position?

Dr. VON BRAUN. Nineteen thousand dollars.

The CHAIRMAN. This bill provides $22,500 for the new Director. How do you feel about that? Do you not feel you are entitled to $22,500?

Dr. VON BRAUN. I think the new Director should take the job and keep it.

The CHAIRMAN. Doctor, in the contracts that Redstone makes under your authority for the Department of the Army with any private companies or laboratories—are they private companies, too? Do you make contracts with corporations?

Dr. VON BRAUN. Yes, sir.

The CHAIRMAN. Supposing they make any discoveries, does the Government get the benefit of those discoveries?

Dr. VON BRAUN. Yes, sir; the question of patent rights is tied up in the contract.

The CHAIRMAN. If you have occasion to contract with another company, you can let that other company know of these discoveries that were made?

Dr. von Braun. Yes, sir. Anything that is being patented under a Government contract is Government property.

Mr. Keating. Is the thrust of one 300,000-pound engine the same as the thrust of three 100,000-pound engines?

Dr. von Braun. Yes, sir.

Mr. Keating. You made the point that it would be preferable to have one 1-million-pound thrust rather than several that made up 1 million. Would it be too technical for us if you explained why that is?

Dr. von Braun. Sir, it is possible, of course, to get a million pounds thrust out of clusters of the most powerful engines we have today. I think the thrust of these is well known. It is 150,000 pounds thrust. So you would need about seven of them to get a million pounds, approximately. It can be done this way, but it is not a very good way of doing it because the cluster of seven engines contains so many components that you lose reliability.

Mr. Keating. In other words, if you have one engine, you have fewer components to go wrong?

Dr. von Braun. Yes, sir.

Mr. Keating. That is the main reason why it is better to do it with one engine?

Dr. von Braun. Also, clustering is very heavy.

Mr. Keating. One final question.

We have all indulged in a good deal of speculation. Suppose in the late forties, or right after the war, we had moved, as you and Dr. York, as you look back on it, would have liked to see us move at that time, when would we have had a satellite in orbit in your judgment?

Dr. von Braun. I think had a satellite crash program been initiated right after the war—I realize it could not have been done because nobody was then interested in this kind of a thing—but from the purely technical angle I think we could have fired a satellite in 1950, 1951, or 1952, something like that.

Mr. Ford. As I recall, Dr. von Braun, you indicated you got the go-ahead on the Redstone program in the spring of 1951?

Dr. von Braun. Yes, sir.

Mr. Ford. From a technical point of view, could you have proceeded at an earlier date?

Dr. von Braun. Yes, sir; in 1946.

Mr. Ford. As I also recall your testimony of this morning, you indicated the breakthrough in the Redstone program in 1954 was the element which gave us the ability to move into the satellite field. If that is so, if we had started earlier than 1951 in the Redstone program, we could have possible orbited a satellite at an earlier date; is that right?

Dr. von Braun. Yes, sir. You can look at it this way: The Redstone program was initiated in 1951. The satellite proposal using the Redstone was made in 1954, and a satellite capability with the Redstone definitely existed in late 1956. Now, had we moved this entire program up 5 years and begun the Redstone development in 1946 instead of 1951, you would have had the satellite capability in 1951.

Mr. Ford. In other words, the scientific knowledge was there, you just needed that much lead time whenever you got the go-ahead signal?

Dr. VON BRAUN. Yes, sir; the most effective way to possess a missile 2 years earlier is to begin work on it 2 years earlier; this simple truth is very often overlooked. We usually wait and wait and then all of a sudden initiate a crash program.

Dr. FORD. I gather in the discussion of the Navaho cancellation, we should have done 1 of 2 things: We either should have pushed the program more rapidly at the time of its inception, or we should have canceled it at an earlier date, because in the meantime the subsequent developments have taken place which in the minds of many made that particular project an obsolete weapon.

How do you know from a technical point of view, and I am sure you have had this in various programs yourself, when to go through this process of cancellation or when to push it more rapidly?

Mr. VON BRAUN. Sir, I have never criticized the cancellation of the Navaho as such, nor the timing of the cancellation. I think it is unavoidable in military developments of this kind that you have to proceed along the lines that appear most promising at the moment, and review such projects at regular intervals to see how they stack up with the rest of the world; in other words, to find out if this is a desirable weapon or has it become obsolete in the meantime. As a result, a certain number of reorientations and cancellations will always be necessary.

I think what happened in the case of the Navaho was entirely natural, and nobody should be criticized for the cancellation as such. I think the question that deserves more attention is what to do with a well-proven research and development group such as this Navaho team, in the wake of a cancellation. Nobody seems to feel responsible for keeping such a team intact. There is a widespread feeling that the Government owes nobody a living and so industry must see for itself that they get the new contracts. This sounds very brave and noble, but it is an utterly wasteful procedure because it is not the businessmen and the salesmen but the scientists themselves, who now have to go out on the road and see to it that the company gets new missile business.

I believe in this area of what you might call program and team stability, we can really learn something from Soviet Russia. In Russia they do not have the problem of competitive bidding, and the concern on the part of the Government employees that they may be accused of favoritism if they award a contract to a plant which, through a procedure which is as formal as it is miraculous, has not been determined to be the most suitable for the job at hand. The plain fact that in a Communist economy all factories are run by the Government direct, makes the procedure of contract award extremely simple: Whenever a development team is available to take on a new job, it just gets one.

I think we have enough missile development teams in this country who have demonstrated repeatedly that they can perform if called upon regardless of whether the missile is a ramjet or a ballistic rocket. If we would just go to these teams with our new missile or space projects and see to it that they are all utilized on a reasonably balanced and constant load level, we would be much better off. At the moment, we turn missile projects on and off like a faucet and do not care what havoc this creates within the carefully organized development teams. To build up a good team takes years, to wreck it takes

a few moments. And yet, these experienced development teams are our greatest single national asset in the race for leadership in missiles and space exploration.

Mr. McDonough. This Navaho project was a North American project?

Dr. von Braun. Yes, sir.

Mr. McDonough. At the time it was discontinued, it created quite a shock in the community out there because of the number of people who were affected by it. We made an effort, the California congressional delegation and others interested, to see to it that those teams were not broken up, if possible. We were conscious of the very thing you are saying here, that the experts would be dispersed and could not be reassembled.

It happened that when these men were notified they would no longer be needed, a number of other firms in the immediate neighborhood took them on. I think many firms took them on to hold them in reserve, not even to put them in immediate employment. Hughes Aircraft, I think, has a large reserve of physicists and mathematicians and scientists.

I do not know what the answer is, but it is very essential that this committee, or the Congress, should give consideration to it in order to create a continuity of thought and development and exchange of data, and to implement some of the basic research that we are studying.

Since you said a moment ago that we could have put a satellite into orbit sooner than we did, were you at all surprised at the time when the Russian satellite was announced?

Dr. von Braun. No, sir; I was not surprised. I was just disappointed.

Mr. McDonough. Following the announcement and the so-called propaganda effect it had upon the United States and the rest of the world, we then attempted to put a couple of satellites in orbit. You say we were prepared in 1956, but we failed in 2 or 3 efforts after that until we put a couple in orbit, did we not?

So we were not quite so prepared as we thought. You say we could have put one into orbit in 1956, and following the Russian satellite, in our attempt immediately after that, we failed a couple of times. I do not mean the Army.

Dr. von Braun. I was solely referring to our satellite capability based on the Redstone missile.

Mr. McDonough. You could have done that earlier with the Redstone?

Dr. von Braun. Yes. The early failures in the Vanguard program were the unavoidable teething troubles of a brandnew missile. These should have been hardly surprising. All our missiles were plagued with such difficulties and setbacks in their early testing phase. This kind of thing is almost accepted as normal operating procedure. In the case of Vanguard these early failures merely received more publicity, that was all.

Mr. McDonough. Are you familiar with the X-15 project?

Dr. von Braun. Yes, sir.

Mr. McDonough. That is a rocket plane, is it not?

Dr. von Braun. Yes, sir.

Mr. McDonough. Man-operated?

Dr. von Braun. Yes, sir.

Mr. McDONOUGH. It is estimated to travel how far into space, 100 miles?

Dr. von BRAUN. Yes, sir.

Mr. McDONOUGH. More than 100 miles?

Dr. von BRAUN. No. I think it can reach nearly a hundred miles in a so-called a ballistic flight pattern. It is designed to be dropped from a B-36, then travels like a ballistic missile, through a ballistic trajectory, but it levels off into a glide after reentry into the atmosphere.

Mr. McDONOUGH. Since that will be the first attempt to send a man to that height, do you think that he can return to earth safely?

Dr. VON BRAUN. Yes, sir. I doubt, however, that this must necessarily be the first attempt to send a man to that height I am convinced we could get a man up there substantially sooner than with the X-15 if we just used an existing and well-proven rocket.

Mr. McDONOUGH. You mean you could send a man in a rocket faster than the X-15 right now?

Dr. VON BRAUN. Yes, sir. We have worked out a detailed proposal to send a man with a Redstone missile 150 miles up. I am convinced, in fact I know, that this could be done sooner than with the X-15.

Mr. McDONOUGH. And return safely?

Dr. VON BRAUN. Yes, sir.

Mr. McDONOUGH. How do you decelerate your speed through the atomosphere coming back?

Dr. VON BRAUN. We propose to separate the nose section with the man from the rest of the missile prior to reentry in the atmosphere. The man himself will be in a pressurized capsule which is inserted into the nose section. The latter is equipped with controllable airbrakes which retard the fall as it gets back into the atmosphere. I must add, however, that this program has not received official approval yet. I do not know why. ARPA knows about it, but has not yet decided on it. There is a question of money involved, I believe.

Mr. McDONOUGH. Can this committee find out why for you?

Dr. VON BRAUN. I would appreciate it very much, sir.

Mr. McDONOUGH. You mean on the rocket-propelled, man-carrying capsule?

Dr. VON BRAUN. Yes, sir.

Mr. McDONOUGH. You want to know why it cannot be done before the X-15?

Dr. VON BRAUN. I know it can be done sooner than the X-15. Our proposal which we recently submitted give all the facts and figures, scheduling estimates and an accurate statement on how much it would cost. It is a relatively cheap program, but to our surprise we have not found much support for the idea yet. Some people have taken the position that it would be nothing but a stunt. But we've been told the same when, back in 1954, we first suggested a minimum satellite with the Redstone missile.

Mr. McDONOUGH. In other words, you want to know why you cannot be authorized to do it?

Dr. VON BRAUN. Yes, sir.

Mr. McDONOUGH. I think it is important to find out.

Dr. VON BRAUN. I am convinced that if we don't tackle this project quickly that this will be one of the next surprises the Russians are going to pull on us—to shoot a man 100 or 200 miles up and get him down again. I am not talking about manned orbital flight. I am

talking about just a manned shot up to that altitude with ensuing recovery.

Mr. McDONOUGH. Now you are speaking about a rocket-propelled capsule in which a man is contained, and the rocket is disposed of, the engine is disposed of. He does not come back with that equipment?

Dr. VON BRAUN. Specifically, our equipment is based on the well-proven Redstone missile again. The idea is simple to bring a man to an altitude of 150 miles. We would separate the nose of the missile from the Redstone shortly after power shutoff. The nose is equipped with aerodynamic brakes and some control equipment. There is also a parachute for the last portion of the descent to land him safely and smoothly on the ground.

Mr. McDONOUGH. He will be contained in a capsule like a satellite is sent into orbit?

Dr. VON BRAUN. Yes; and he will be in outer space for over 6 minutes during which he could make many observations.

Mr. McDONOUGH. He can propel himself into space after he is released from the rocket, and return?

Dr. VON BRAUN. Shortly after the Redstone engine goes out, the nose section with the human capsule will be separated from the rocket. Nose section and man will then coast unpowered through the apex of the trajectory 150 miles up, and thereafter descend back into the atmosphere. Finally he will land on the ground where we will retrieve him.

Mr. McDONOUGH. I think, Mr. Chairman, this committee should find out why they have not been authorized to proceed on this development.

The CHAIRMAN. We can consider that in executive session. Will you bring it up?

Mr. McDONOUGH. Yes.

Do you have any volunteers for this, Doctor?

Dr. VON BRAUN. Yes, sir.

Mr. McDONOUGH. You have?

Dr. VON BRAUN. Yes, sir.

Mr. KEATING. I was told down there that a dozen young fellows are all ready to move.

Mr. FULTON. How about some of us on the committee? I am willing to try it.

Mr. McDONOUGH. Lockheed has already assigned the job for taking up the X–15.

Dr. VON BRAUN. The X–15 cannot possibly be ready to reach 100 miles altitude at the time when we could hit 150. It will be substantially later than our schedule.

Mr. McDONOUGH. Something in 1959 or 1960?

Dr. VON BRAUN. Yes, sir.

Mr. McDONOUGH. You could do it quicker than that?

Dr. VON BRAUN. Yes, sir. Quicker than the X–15, and we could also go higher.

The CHAIRMAN. Mr. Feldman, have you any questions?

Mr. FELDMAN. Yes, sir.

The CHAIRMAN. I want to say that you gentlemen have been very cooperative, and we appreciate it. It has been most helpful. We are pioneering ourselves. I am frank in stating that I am starting practically from a position of ignorance, but trying to apply my common

sense as a legislator as to what is best to do in the interest of our country. You are helping us invaluably.

Mr. FELDMAN. Dr. von Braun, this is corollary to the question asked by Congressman O'Brien of New York. We talked about spending a lot of money for these projects. But we are also concerned with this question of payoff, the quid pro quo.

For example, over $14 billion has been spent in connection with the atomic energy project of one kind or another. I am advised by an authoritative source that the capitalized payoff from isotopes alone in the case of atomic energy has been greater than the $14 billion we have spent on these projects.

Do you feel that the peaceful-use payoff, like the question of weather control or weather forecasting, or, the question of communications and other developments we do not know of at present, will have a corresponding value?

In other words, will they, too, pay off in terms of dollars and cents just as the isotope has paid off in the case of atomic energy?

Dr. VON BRAUN. Yes, sir; I am convinced that certain applications of space technology will become very valuable payoffs. Particularly, the communications satellite is promising in this regard, also the weather forecasting satellite. Now, the communications satellite can be a useful commercial tool, particularly in two areas. One is as a radio link for global television. Imagine several satellites equipped with relay transmitters, and working in compound. One satellite at the time would always be in direct line of sight contact with an American TV transmitter station, while the others would pick up these relayed signals and pass them down from whatever country they happen to be over.

With six relatively small, unmanned satellites assigned to this mission, you can provide a global television hookup.

In the field of radio communications, it is conceivable to build satellites equipped with radio receivers and multichannel type recorders to which you can radio telegrams or letters while the satellite is speeding over one city. Upon a signal from the ground from another city the satellite is instructed to play back whatever messages were addressed to that city; as the tapes are played back they are cleared to take on new messages for the next major city to be flown over by the satellite. In a modest way, we are using this same technique already on Explorer 3, which has a tape recorder and a playback feature and a coded command receiver, so that on instruction from the ground the tape can be played back. This same technique, in a somewhat more elaborate fashion, lends itself beautifully to general communications services such as I just described.

If you combine the modern coding techniques that are used in electronic digital computers with these multichannel tape recorders, you get a tremendous mail handling volume. These modern electronic coding methods permit the printing of the text of a whole book within a few seconds. It has been computed that with 6 communications satellites of this kind one could handle the entire mail volume of the whole earth.

When you further consider that such a satellite message would never take longer than 1 hour from sender to receiver, it would appear reasonable to charge at least 1 penny a word for this global mail service. This would not only pay for the service as such, but in

addition could provide enough funds for trips to the moon and other ventures into deeper space.

Mr. FELDMAN. It would pay for itself many, many times; is that right?

Mr. FULTON. Actually, you could have a recorder on that basis which would play back information on all the armies, the navies, and air forces of the whole world, and you would know wherever one of them might be on this kind of satellite; is that not right?

Dr. VON BRAUN. Yes. You could actually take over the job of hauling long-distance mail from the post office and make a source of revenue out of it.

Mr. FULTON. For military purposes, you would know where everything is all the time, all the armies, the navies, and the air forces of every country in the world?

Dr. VON BRAUN. This would be the job for a military reconnaissance satellite.

Mr. KEATING. He did not mean that the Postmaster General would take over the military.

Dr. VON BRAUN. I think Mr. Fulton was talking about the television satellite looking down on potential enemy territory and playing the pictures back over friendly territory.

Mr. FULTON. If there were a change from the original photographs, the satellite itself would record where the change was?

Dr. VON BRAUN. Yes, sir.

Mr. FELDMAN. The expenditure, then, would more than pay for itself. Would you go even further and say, for example, that, just as the automobile industry created a great deal of employment and was followed in turn by the radio industry and television industry and the airplane industry—would you say, after the thinking stage was concluded in connection with rocketry or satellites and we had gone into production, that a large segment of our labor would be employed in the projects?

Dr. VON BRAUN. Yes, sir; most certainly.

Mr. FELDMAN. And that instead of unemployment, we might have a shortage of labor?

Dr. VON BRAUN. I firmly believe rocketry and space technology will create a new industry just like the aviation industry and many others. In fact, this process is already in full swing.

Mr. FELDMAN. How long would you estimate it would take to go from the thinking stage into the development and production stage?

Dr. VON BRAUN. There are many space projects ready to go immediately into the hardware development stage. All that is needed is money.

Mr. FELDMAN. That would begin to employ people, is that right, in a useful capacity?

Dr. VON BRAUN. Yes, sir.

Mr. FELDMAN. Addressing ourselves again to the legislation, Doctor, should there be, within the Agency, a military division similar to that of the AEC's Division of Military Application, which is headed by an active member of the Armed Forces and a military liaison committee composed of representatives of the Army, the Navy, and Air Force?

Dr. VON BRAUN. You are referring to the National Aeronautics and Space Agency?

Mr. FELDMAN. I am referring now to the new NASA proposal.

Dr. VON BRAUN. Yes, sir.

Well, I feel the military and the scientific programs are so closely interwoven that it is absolutely necessary that there be a close and continuous cooperation between the armed services and this Agency. I think AEC has set a fine example here, and AFSWP, the military liaison group to AEC has demonstrated how to do it.

Mr. FELDMAN. You would agree that setup is a useful one and has worked very well in the case of the liaison between the Armed Forces, the various brances of the Armed Forces, and the AEC?

Dr. VON BRAUN. My own personal experience in this area was very favorable. We found very smooth cooperation in everything we ever did jointly with AEC.

Mr. FELDMAN. In connection with the area of aeronautics and astronautics, would you think there should be a separation of the two functions? Is the science involved in aeronautics different from that involved in astronautics?

Dr. VON BRAUN. Aerodynamic problems are quite important in rocketry and space vehicles, although of course, there are many other problems of at least equal importance such as electronics and rocket propulsion.

I think Dr. York answered this question very well when he said the most attractive thing about NACA is that it constitutes an assembly of exceptionally fine talent and great experience. If this talent and this experience and also the fine NACA facilities become the hard core of the National Aeronautics and Space Agency, then you have something to begin with and that alone has decisive advantages over forming a brand new agency from scratch.

Mr. FELDMAN. Do you have any ideas in connection with the provision in the proposal concerning an advisory group of 17 members?

Dr. VON BRAUN. I think I said at the beginning of my testimony that I feel that the charter of NACA requires some rather drastic changes to enable NACA to take care of the administration and the extensive managerial problems of an ambitious space program. From its present status as an advisory committee and a group of loosely connected institutes for supporting research, it must be transformed into an executive management agency capable of handling large contracts and supervising the allotment of large sums of money for them. This means, in my opinion, that the executive hand of the director of the NACA must be strengthened—so that he would assume a role comparable to that of a corporation president—and that the role of the present main committee of the NACA should be transformed into that of a board of directors, so to speak.

Mr. FELDMAN. Do you feel that there is anything in the organizational structure in Peenemunde that could be used beneficially in any project we might undertake or any new agency we might create?

Dr. VON BRAUN. The organization of Peenemunde, at least until spring, 1944, was very similar to our present operational setup in the Army Ballistic Missile Agency. There was a military commander and there was a completely civilian research and development division, and in addition there was a contract administration to handle the legal and fiscal portion of all outside contract work.

Mr. FELDMAN. The patterns are much alike?

Dr. von Braun. The pattern was very much the same. I would say, even to the extent that at Peenemuende, too, about 50 percent of the money was spent outside for industrial support, while the other 50 percent were spent in house.

Mr. Feldman. Dr. DuBridge of Cal Tech stated that manned satellites provide a program of a Buck Rogers variety, and the moon bases are just pseudomilitary expeditions. Do you have any comments to make on that observation?

Dr. von Braun. I have never expressed myself one way or another on the military significance of the moon. I believe it is at least premature to justify any moon flights at this time with a military necessity of establishing a fortress on the moon. In fact, I have grave doubts as to whether the moon really has, at this time at least, a military importance comparable to that of an artificial, orbital station in space. As to the military importance of such artificial, manned satellities I have not the slightest doubt that 10 or 15 years from now there will be large manned space stations, but I think they will mainly serve scientific purposes and for observation—both astronomical observations and also terrestrial observations, weather observation, weather forecasting and military reconnaissance. But I think in addition to these large, manned space stations there will also be smaller, more maneuverable orbiting vehicles of very great military importance, and in the not too distant future, too. And these vehicles will not only be suited for reconnaissance. No matter how skeptical other men have expressed themselves in this regard: I firmly believe they will play a most important military role as carriers for guided orbit-to-ground missiles.

I am convinced that 10 to 15 years from now, space priority will assume the role of today's air superiority.

Mr. Ford. Mr. Chairman, may I ask one question?

The Chairman. Yes.

Mr. Ford. In your discussion, you talked of shooting a man out into space 150 miles, using the Redstone vehicle. In time, if you got the go-ahead and money and otherwise, how long would it take you before such a project could materialize?

Dr. von Braun. Approximately 1 year.

Mr. Keating. That could be followed, could it not, by the transportation of several people in one of these capsules? That would be a natural development, would it not?

Dr. von Braun. Yes, sir. The Army feels that in the pattern of future fluid ground warfare there is a very definite need to use large ballistic missiles of several hundred miles range even for the transportation of troops and supplies to fighting areas surrounded by the enemy.

Mr. Keating. I do not want to involve you in any interservice matters, but is it not possible such a method of transportation of personnel in military operations by such capsules could well be more economical than transportation through the atmosphere by plane?

Dr. von Braun. Yes, sir; definitely, particularly when you consider the aircraft attrition rate in areas where the enemy may enjoy local air superiority. I think flying large quantities of troops by aircraft into such areas and parachute them down to the ground becomes pretty costly in terms of losses of life. Today's troop carriers are slow,

lumbering planes that are easy prey for modern fighter planes, and dropping troops by individual parachute into terrain held by a strong adversary has always been a dangerous thing, too. Ballistic missiles would land the men in batches of 20 or even 50, and the landing capsule would constitute quite a concentration of firepower.

Mr. FULTON. If you can go up 150 miles into the air in a capsule, then it becomes possible to say, why not direct it across the Atlantic Ocean. It is only a case of the amount of propellant you would put in.

How long would it take you then in one of those capsules at 150 miles altitude to cross the Atlantic Ocean?

Dr. VON BRAUN. Sir, this particular vehicle, the Redstone, which we proposed for that manned ascent to 150 miles altitude, could not do that. But with larger rockets, for example, our new family of ICBM rockets, it would be possible to do that. In fact, they could even put a man in orbit and retrieve him out of the orbit after he has gone around the earth several times.

Mr. KEATING. At what rate of speed would this manned capsule be propelled to go 150 miles up?

Dr. VON BRAUN. It would have an approximately 4,500 to 5,000 feet per second velocity at power cutoff, and it would almost come to a standstill at the apex of the trajectory. It would have again a speed of about 5,000 feet per second when it reenters the atmosphere.

Mr. KEATING. On the circumference of the earth, how much of an arc would he have traversed in this experiment you are thinking of?

Dr. VON BRAUN. We could conceivably shoot him straight up, but for recovery reasons it would be important to select a suitable landing site.

Mr. KEATING. How far would he actually travel?

Dr. VON BRAUN. We picked a landing site about 150 miles from the launching point.

Mr. KEATING. How long would that take?

Dr. VON BRAUN. The entire flight?

Mr. KEATING. Yes.

Dr. VON BRAUN. Approximately 12 minutes.

Mr. KEATING. If it was on a 3,000-mile basis, he could probably go across the ocean in 1 or 2 hours?

Dr. VON BRAUN. Less than that.

Mr. KEATING. How long then?

Dr. VON BRAUN. About 30 minutes.

Mr. KEATING. You have said that in 84 days you have been able to get a vehicle into orbit. Could you have done in less than 84 days if you had all the equipment, personnel and everything put into your hand with the instructions?

Dr. VON BRAUN. Are you talking about Explorer 1 now?

Mr. KEATING. Yes.

Dr. VON BRAUN. We needed 84 days because when we finally got the go-ahead we were told to quickly build a satellite—payload that included certain cosmic ray and meteor density experiments for the International Geophysical Year. It was simply the schedule for this new IGY payload that determined the time it took us to get Explorer I into orbit. Without that requirement we could have done it in half the time.

Mr. KEATING. So if you had not had specific instruction for the kind of rocket vehicle for Explorer I, you could really have put it up in about 40 days?

Dr. VON BRAUN. Yes, sir: but not because we are that good, but simply because we had the rocket hardware sitting around.

Mr. KEATING. Thank you very much.

Mr. McDONOUGH. On this so-called space vehicle or man-contained capsule, going to the apogee and then returning, does he return under gravitational force or with some propellant?

Dr. VON BRAUN. No, he falls back into the atmosphere from the height of 150 miles and reenters the atmosphere at approximately Mach No. 5. That is a speed of about 5,000 feet per second. From this initial reentry velocity he is then slowed down by atmospheric drag.

Mr. McDONOUGH. He has no control over his return flight?

Dr. VON BRAUN. No. A parachute will be deployed when, at an altitude of about 7,000 feet, his speed has become subsonic. The parachute slows him down sufficietly to land smoothly in the ocean.

Mr. McDONOUGH. There is no propellant in the capsule?

Dr. VON BRAUN. No.

Mr. McDONOUGH. It would mean he would be slowed by a parachute or other means?

Dr. VON BRAUN. Yes.

Mr. McDONOUGH. With your present plans and your present possibilities today could you direct his flight to the 150-mile elevation and land him at a specified point?

Dr. VON BRAUN. We could place his landing point within about half a mile from the ship which would fish him and his capsule out of the water.

Mr. McDONOUGH. Could he land on ground?

Dr. VON BRAUN. He could, yes; but it is simpler to land him in water.

Mr. McDONOUGH. Safer, also?

Dr. VON BRAUN. For a number of reasons.

First, the final impact is softer; secondly, in water you can cover a large surface area with a ship very easily. On land, if the thing hits a rock or boulder, impact conditions may be uncontrollable. If it lands in the boondocks it may be difficult to reach the landing point fast enough.

Mr. McDONOUGH. All of this could be done within what period of time?

Dr. VON BRAUN. One year.

Mr. McDONOUGH. One year from now?

Dr. VON BRAUN. One year from the word "go."

Mr. McDONOUGH. Thank you.

The CHAIRMAN. Thank you very much, Doctor. We are very happy to have had you with us. For myself and the entire committee, I express our sincere thanks.

The next witness is Dr. Theodore C. Merkle, head of the Research Division of the University of California Radiation Laboratory, Livermore, Calif., a facility of the Atomic Energy Commission.

Dr. MERKLE. The Radiation Laboratory is a contractor to the Atomic Energy Commission.

The CHAIRMAN. Doctor, we will be very glad to hear you.

STATEMENT OF DR. THEODORE C. MERKLE,[3] HEAD OF RESEARCH DIVISION, UNIVERSITY OF CALIFORNIA RADIATION LABORATORY, LIVERMORE, CALIF., CONTRACTOR TO THE ATOMIC ENERGY COMMISSION

Dr. MERKLE. Mr. Chairman, I have been asked to present at this meeting a few comments concerning the relationship which exists between nuclear propulsion schemes and chemical propulsion schemes. In particular, I would like to talk about the possibilities that nuclear energy offers in the traveling of large distances in space.

Before I begin, I would like to set the stage a little bit, if I have your permission. You have been talking about outer space. I was a little surprised to find out that you are considering picayune distances in the order of a couple of hundred miles. I would like more to talk about outer space as being that volume of space lying between the orbits of Mars and Venus.

As you know, the earth is intermediate between these two planets, very nearly, and the distances then which are to be considered are distances of the order of 50 million miles as the least.

It is certainly true that you can call a trip to the moon a flight into outer space and back again, but I do not believe that it is semantically correct to refer to a distance of only 100 miles into the atmosphere as a flight into space.

Now, travel over these very large distances that I have indicated, with rockets, requires a couple of things. I would like to mention what they are.

In the first place, to propel the rocket, we must have available a large quantity of matter to throw away. If you throw it away very rapidly, then the rocket goes in the other direction very rapidly. The quantity of matter I shall refer to as the reaction mass.

In the second place, you have to have a large quantity of energy to give to this reaction mass. That is, you have to spend a lot of energy to speed up this material you are going to throw away, usually from the rocket nozzle, and send it away from your rocket as rapidly as you can.

This point is not trivial because the more rapidly you throw the matter away, the bigger is the payload for the rocket. It is a matter of concern if you wish to move around in the solar system with any convenience at all that a fairly respectable fraction of the entire launching weight be payload rather than fuel and propulsion machinery.

Now, if we hold these few ideas in mind, I can now point out what the difference really is between chemical rocket schemes and nuclear rocket schemes. In chemical rocket schemes, the energy source and the material to be thrown away are one and the same. You combine gasoline, or what have you, with liquid oxygen or use some other suitable combination of chemicals. From this combination you get energy which heats the material and flings it out of the rocket nozzle.

The one advantage that a nuclear scheme possesses is this: In the nuclear scheme the material that is to be thrown away and the material which provides the energy are not the same things. This makes the nuclear rocket devices quite different from the chemical rocket devices. Let me illustrate.

[3] Merkle, Theodore C(harles), Jr, 883 Yale Way, Livermore, Calif. Physics. Union City, Ind, Jan. 19, 19; m 41; c. 3 B. Sc., Michigan, 40, M. Sc 41; Ph. D. (Physics), California, 50. Instr physics, California, 50–51, asst. prof, 51–53; Physicist, Radiation Lab, 53—U. S. N. R, 41–46, lt. comdr. A. A.; Physical Soc; Asn. Physics Teachers. Nuclear physcis.

In a nuclear rocket, you would presumably, if you are talking conservatively, consider the fission rocket, that is a machine which somehow extracts energy from the fission of uranium 235 or plutonium or some other fissionable material, and this energy would be used in one way or another to accelerate the reaction mass that I mentioned a while ago, and thus give momentum to the rocket.

Now, one pound of uranium, if fully burned, will generate about as much energy as 1,000 tons of coal fully burned at the earth's surface. And therein lies the reason that many of us believe that before space exploration, in the sense that I an using the word "space," becomes fully practicable; it will be desirable, although not technically absolutely essential, to have the development of a nuclear energy source for rocket propulsion Just in that 1 fact, 1 pound of uranium is roughly equivalent to a ton of coal burned; then if we remember that in a chemical rocket we must carry along an oxidizer as well as a fuel, this will be approximately equavalent to 2,000 tons of rocket fuel Now, that gets me off the energy hook very nicely.

One can see that the power source that might be used to propel a rocket could consist of some type of fission reactor and the weight of actual fuel, that is the material that produces the energy that it must carry, would be a trivial part of the entire rocket dry weight. But I am still not off the other hook I still have to carry reaction mass in my rocket to throw away. So immediately the question becomes, how much of that will I have to have?

There is a relation between the speed that I give to a rocket and the speed at which I am throwing away material. The faster I can eject material from the rear of my rocket, the smaller the amount of material I must carry with me to get an equivalent performance. This is sometimes described in rocket language by a number which is called the specific impulse of the rocket, and the specific impulse of the rocket, when multiplied by the gravitational constant, for reasons I shall not go into, is just equal to the velocity of exhaust.

Now, the specific impulse of a nuclear rocket can be anything you care to name, if you build the right kind of rocket, which means in principle that so far as the velocity with which I eject particles is concerned, it is conceivable that one can set the velocity to any figure that is convenient and the convenience will be determined by other considerations than this particular law.

Now, what is practical?

What seem to be practical at the moment are two types of rocket proposals. One is called the heat-exchanger rocket. In the heat-exchanger rocket, we must imagine that we have a typical rocket nozzle and a large pressure vessel hooked onto it which looks something like a barrel. In this barrel there is the mass of a nuclear reactor, and there are a lot of holes drilled through it. The nuclear reactor generates heat at any rate you care to set. If you make it generate heat too rapidly, it will melt itself. So the rate at which you generate heat then in this barrel will be set by the amount of reaction mass you can push through the barrel

That reaction mass will be heated and ejected from the rocket in the same way that a chemical rocket functions.

Let me go over that briefly. The heat-exchanger rocket is the analogue of the large liquid fuel chemical rocket. The only difference is that the fire is contained within the body of the nuclear reactor and

is not provided by the combustion of propellants. The fire temperature will be limited by the kind of materials from which you can build this heat exchanger, as it is called.

Now, there are programs in this country to study such rockets. Unfortunately, the details are classified. However, it is possible to imagine a variety of temperatures, when considering what performance one would get, without going into classified areas. It is possible to consider temperatures as high as the melting point of the most refractory material known; whether this can be done or not is a classified matter, but that temperature for the most refractory material known would be (some of the carbides) above 3,000° Kelvin. That is not so hot as the flame in a chemical rocket.

But you don't have to throw away the same kind of materials that you do in a chemical rocket and because you have at your disposal the choice of material you wish to throw away, it is possible to get, or imagine that you can get, superior performance from this heat exchanger rocket relative to the chemical rocket. That is the simple scheme which in the trade we used to call "Old Pokey"; the Old Pokey rocket is the heat-exchanger rocket. This is the kind you read about in all the Sunday supplements, or have read about. It is the kind described in Russian literature years ago. It is the kind of scheme that has been talked about either in science fiction or elsewhere since about 1928.

The second scheme which appears to be practical is called the ion rocket. In this type of device, you wish to avoid the problems of the heat exchanger. To do that, we use a nuclear-energy source (and it has to be a nuclear-energy source because the demands are very heavy) to generate electricity in the rocket. This electricity is used to operate an accelerator, an accelerator characteristically giving about 2 or 3 kilovolts of energy to the particles that are to be thrown away.

Such an accelerator then can give a very high velocity to the particles you throw away, and therefore the amount of matter that you must throw away to achieve a given velocity is less than it otherwise would be.

There are, unfortunately, practical limitations at the moment which keep the ion rocket from being able to take off from the earth's surface. It is by its nature, and that nature is determined largely by the horsepower per pound that you can get in electric and turbo machinery, it is by its nature restricted to very low values of thrust. Therefore, it cannot leave the earth's surface by itself. However, such an ion rocket in principle can leave an orbiting space station and proceed to accelerate over very long periods of time so that it acquires quite high velocities, and with such devices you can calculate possible trips to such planets as Mars and Venus.

Actually, ion rockets can be imagined to go farther than that, but the length of time required for the journey begins to get rather long.

So these two schemes are the schemes that look most promising in the field of nuclear energy. One of them is being worked upon by the Los Alamos Laboratories on a classified basis. The other is being explored by a variety of people at a very low level, but so far as I know, a vigorous program for the development of such a thing has not yet been mounted.

Mr. McDonough Is there any Government program on any one of these?

Dr. MERKLE. The Los Alamos program is a Government program. The ion rockets studies that have been made so far have been in part under Government sponsorship and in part done by various people at their own expense. I would like, however, to make a few more comments.

The Old Pokey rocket, the one that Los Alamos is working on, is much nearer to fruition than the ion-rocket schemes. The ion-rocket schemes are a sort of evil gleam in people's eyes at the moment.

Mr. FORD. How do you spell ion?

Dr. MERKLE. I-o-n, a charged particle. The ion rocket schemes require a certain amount of very basic development in their components before they can be taken too seriously.

The Old Pokey rocket also requires certain basic developments in its components before it becomes a reality, but there is at least an order of magnitude difference in the difficultness of these problems. The Old Pokey rocket will get there first.

Mr. FORD. Is the distance between Old Pokey and ion because one is an old-fashioned affair?

Dr. MERKLE. At Livermore, we considered the Old Pokey rocket as the most stupid nuclear rocket you can cook up. It has only one advantage; it is very likely to work.

Mr. FORD. Why is it called stupid?

Dr. MERKLE. You see, it is not very imaginative. It is the sort of thing you would think of, just offhand in an idle moment. When you look at the numbers, it still makes a reasonable amount of sense.

The main problem in the Old Pokey rocket is obtaining materials that can stand up to a very rugged environmental condition, both from the standpoint of chemistry and from the standpoint of thermal stress. These materials appear to be on the horizon. The progress that has been made is classified, but there are no final conclusions as yet.

The ion rocket, on the other hand, has problems that are beyond just the materials problems. It is a matter of developing high-energy sources; there is a matter of developing very high-power density in reactors; there is a matter of developing a heat sink against which the heat engines of the reactors must run, because in space there is no way of getting rid of heat except by radiating it. All steam engines have to have a condenser some place in a closed cycle. In space that condenser or device that is equivalent will have to radiate energy away into space. This gets you into the materials problem business again.

So, for the ion rocket in addition to the ion source development, there is the heat-sink problem that has to be looked into and, last but not by any means the least, is the matter of highly reliable electrical components with a very good ratio of power to weight.

At the present time, standard electrical components on aircraft can be as good as a pound or so per horsepower. It would be very nice if this could be cut down to a tenth of a pound or so per horsepower.

There is no basic law that gets into one's way, but such development has not been pushed at the present time. For both the Old Pokey and the ion rocket, it is not clear how long a time would be required for doing the material developments.

On the other hand, there are no physical laws that we know of that say you can't do the material development. So I think it would

be fair to say that both schemes probably will, in the course of time, become quite practical.

This is a very brief introduction. I have mentioned what the main advantage is in using nuclear energy, and I have mentioned the two schemes which I personally believe have a chance of succeeding.

Now, what can you do with it?

I do not wish to give any testimony as to the possible uses for space exploration, military or otherwise. The kind of voyages you could manage undertaking with either of these schemes would be trips, as I mentioned before, to the two nearest planets. To the moon, one goes without saying, this just tumbles out of the thing almost automatically. This is a round trip sort of thing.

Mr. KEATING. At what speed?

Dr. MERKLE. The speeds vary. It depends on what you want to give the rocket in the way of a payload and how conveniently you want to return. The increment of velocity that must be given to the rocket is the usual figure of merit that is used.

For a trip to Mars and back, following a parabolic curve, the velocity that must be given to the rocket overall is about 24 miles per second, not an exorbitantly high speed. This can be compared to escape velocity from the earth, which is 7 miles a second. The reason for the large difference is that some of the delta V you give is used to slow down at the other end so that you don't fly into Mars in an uncomfortable way and can accelerate away from Mars again and brake coming back to the earth.

This gives you some kind of idea.

Mr. FULTON. Before you leave your general field, could I ask if you would comment on the photon propulsion?

Dr. MERKLE. The photon scheme as nearly as we are able to tell makes no sense whatever.

Mr. FULTON. Has any investigation been made on the use of light as a propellent?

Dr. MERKLE. Yes. It is a fairly easy thing to explore on a theoretical basis and a great deal is known about the behavior of photons. The big hooker is that the photon has very little momentum for a large amount of energy and therefore the materials that are doing the radiating of photons are exposed to rather extreme conditions if you wish to get any kind of acceleration out of the system at all.

Mr. FULTON. Your judgment is that that field is completely impractical?

Dr. MERKLE. I think that the noise that has been made about photon rockets has been made on a theoretical basis, considering only the photons and not how you got them in the first place.

Mr. McDONOUGH. Comparing the photon to the ion and Old Pokey, are the ion and Old Pokey still on a theoretical basis?

Dr. MERKLE. I would say Old Pokey is half theoretical and half practical by now. The ion scheme is theoretical but theoretical on a basis that is quite firm in that many studies have been made considering the entire problem, not just the problem of accelerating the ions, for example, but how you get the reactor, how you get the heating, how you make the ion sources and the like.

Mr. McDONOUGH. You are speaking of a source of power here and you are not considering the environment of the vehicle, of the man, the environment man will be in during this space travel, are you?

Dr. MERKLE. Let me see if I understand what you wish me to say.

Mr. McDONOUGH. Well, the condition in which he would be enclosed. He would be on a long trip. He would be traveling at 1,440 miles a minute, 24 miles a second.

Dr. MERKLE. That is not really correct. That is the velocity increment overall. His peak speed would be in the neighborhood of 8 or 9 miles a second.

Mr. McDONOUGH. Then on a trip to Mars at the closest point of 36 million miles and return, that is a long trip, is it not?

Dr. MERKLE. That is quite a long trip. As a matter of fact, it would take—with very highly efficient power sources which don't exist but might be developed—it would take 150 days.

Mr. McDONOUGH. He would have to be provided with some safe living conditions.

Dr. MERKLE. He would indeed.

Mr. McDONOUGH. You are not speaking of such things.

Dr. MERKLE. No, sir. I am speaking just of the power source. It would appear as follows. That the problem of containing a man, feeding him, nourishing, whatnot, is a more straightforward one than the problem of trying to find the propulsion machinery that will get him there and back again.

Mr. FULTON. Did you mean that 24 miles per second is accumulated velocity?

Dr. MERKLE. That is accumulated velocity, that is the total velocity. It is lost at certain points and gathered back at certain points.

Mr. KEATING. What is the advantage of the ion over Old Pokey?

Dr. MERKLE. The ion rocket has advantages over the Old Pokey if you can make it work, when you are considering fairly long trips such as Mars or Venus. As far as going to the moon and back is concerned, probably two stages of Old Pokey or a large number of stages of the chemical rocket would be more expeditious.

But if you wish to go to Mars and back, and if you look at the time required, you find sort of funny things. The ion rocket will accelerate for a long period of time and therefore can make the trip in a shorter length of time than it would be in the two-stage Old Pokey machine.

The principal advantage, as far as just theory is concerned, then lies in the possibility in the future of getting an ion rocket with a high enough specific power to get to Mars and back in 150 days instead of something like 970 days which you would calculate for the 2-stage Old Pokey scheme. Of that 970 days, by the way, 447 days are spent in waiting for the planets to get back in position so that you can make the return trip.

Let me mention one other thing. To my mind the important advantage and therefore the main reason for pushing into the ion rocket concept, even though it looks very formidable, lies in the question of this reaction mass I mentioned a while ago. For an Old Pokey nuclear rocket it is desirable to use the lowest molecular-weight material that you can for the reaction mass. The lighter the molecules of material you throw away, the faster they can go. Therefore, whenever anyone talks about space travel using Old Pokey rockets they always talk about using liquid hydrogen as the reaction mass. Now liquid hydrogen can be kept in very large tanks but to keep liquid hydrogen for 900 odd days in a tank of thin stainless steel

in view of possible small meteorities, and other things, is to a certain extent a little frightening. I don't think I would like to take that trip. I am not sure you could hold it for 970 days.

The ion rocket, on the other hand, can use more convenient materials. One convenient one is cesium. You can have this in the metallic state in space so that the fuel that you are going to feed into your ion rocket then consists of wires which you have in big spools and these are not very seriously damaged by waiting around.

Cesium is an element.

Mr KEATING. What is the atomic weight of cesium?

Dr. MERKLE. It is one of the alkali elements.

Mr. KEATING. The difficulty with the ion rocket, the greatest obstacle, is getting that off the ground.

Dr. MERKLE. I would not say that. The greatest obstacle is finding out how to build one. After you have built that there are two possibilities really. One is that it can be built on an orbit around the earth.

That is, you truck the materials to that orbit by means of large chemical rockets or large nuclear rockets and you construct this ion rocket on the orbit. The other possibility is that it is built on the earth and it is a second stage for a large chemical or large nuclear rocket, either one.

Mr. KEATING. That is what I was coming to, whether that would overcome the obstacle of getting it up.

Dr. MERKLE. That is correct.

Mr. KEATING. Then it would be either, as you say, assembled in outer space——

Dr. MERKLE. Near outerspace.

Mr. KEATING. I get your point. That is a feasible arrangement?

Dr. MERKLE. Well, it is a manageable arrangement. Now this brings me to the next point I wish to discuss.

Mr. FULTON. Cesium is actually in practical use today in the atomic submarine, is it not?

Dr. MERKLE. Cesium is used in many, many places. It is an active alkali element. It oxidizes rapidly. You normally have to keep it in oil. By the way, don't let me scare you. You don't have to use cesium.

Mr. McDONOUGH. What is the difference in atomic weight of that and hydrogen?

Dr. MERKLE. Enormous. The main point is that you accelerate this cesium in an accelerator which gives it an exceedingly high velocity.

Mr. McDONOUGH. But it is much heavier.

Dr. MERKLE. I wish I could remember that property of cesium. I think it is in the neighborhood of 150 but it is much, much heavier than hydrogen and you make up for this heavy mass by giving it a high velocity. The thing that limited you in the Old Pokey was that there was a fixed temperature in the heat exchanger and therefore highmass particles achieved only a low velocity.

If you were to run cesium through an Old Pokey it would be utterly worthless for that reason. If you had at your disposal the voltage in accelerator tubes then you could set that for each material and it only has to be 2,000 volts to give cesium a specific impulse of about 6,000, which is considerably above anything that you can

do with Old Pokey and about a factor of 10 or 12 more than you can do with the most manageable exotic chemical fuels.

You really get a high specific impulse with the ion rocket.

The CHAIRMAN. The Chair recognizes Mr. Sisk.

Mr. SISK. Mr. Chairman, I have been particularly interested in Dr. Merkle's background in his work at the laboratory. I have been concerned with some practical applications of your knowledge and to what extent the programs are underway at present in the applied use of nuclear power in missiles or in a potential space vehicle.

Let me ask, in view of the discussion you just had with some of my colleagues, is there a laboratory doing work on this system?

Dr. MERKLE. This is something I wanted to take up here as a general heading. Maybe I shall do it as an answer to your question. The point I want to stress is that I am not talking about what you can build next year or the year thereafter; these systems are not schemes which enable you to get something into space as soon as possible. For that chemistry has to be used, it is already here, it is already being. The Old Pokey rocket presumably could become operational then in a period of time like 5 to 10 years. By operational I mean you could have one operating, not that there would be a whole lot of them.

The ion rocket will take somewhat longer, so that I am actually talking now about things that you will probably seriously want a decade from now. I bring this up because if you want them a decade from now you will have to start basic laboratory work and keep it rolling steadily for that whole time.

Mr. SISK. That is the point I want to bring up. As I understand, there is no work going on at the present time in laboratories on this. I think probably there should be. That is the thing I am interested in. If we want it a decade from now or 20 years from now, how are you going to get it if you don't get work started?

Dr. MERKLE. There is a lot of work going on now on the Old Pokey rocket, as you know. At Los Alamos there is a sizable program. Ion rockets are not quite so well thought of because they present much more difficult problems.

I believe that some feelers have been put out by a variety of agencies doing work on the ion rocket business and there are in fact some studies being made currently at the request of Government agencies.

Mr. SISK. Do you feel it is too early to start laboratory work on this program?

Dr. MERKLE. On a rocket, on an ion rocket?

Mr. SISK. Yes.

Dr. MERKLE. On an ion rocket per se—let me make a distinction between the research you have to do before you say what you ought to undertake and the development you must do after you know what you want to undertake.

I think the ion rocket comes in the category of things that might profitably be researched until you know whether you want to do it or not, and at how rapid a rate.

Mr. SISK. How much basic research is going on now in the ion rocket?

Dr. MERKLE. I do not know, but it is small.

Mr. SISK. With reference to your particular laboratory, of course, I am interested in Project Rover. What is its status?

Dr. MERKLE. Project Rover exists at the Los Alamos Laboratory. It does not exist at the Livermore Laboratory. It was discontinued there in January 1957.

Mr. SISK. Why?

Dr. MERKLE. We were instructed by the Atomic Energy Commission to discontinue this work and the reason they instructed us to do so was because there was not sufficient money authorized by the Bureau of the Budget to support both Los Alamos and Livermore in the Rover project.

Mr. FULTON. It was purely a money matter.

Dr. MERKLE. So far as I understand, this was purely a money matter. This was pre sputnik that this decision was made.

Mr. SISK. In order to bring us up to date, was there not something special within the last year or so on a new start in your Laboratories?

Dr. MERKLE. Livermore acquired Project Pluto in place of Project Rover. Project Pluto is a nuclear ramjet project. It is for military application strictly.

That project has absorbed the efforts of the people that used to be on the Rover project. There has been no question about reopening the Rover project at Livermore, to my knowledge.

Mr. SISK. Dr. Merkle, in view of the fact that the program is operating in the Laboratory at the present time, do you agree it should not be or do you think work should be going forward on it?

Dr. MERKLE. This is a question that really involves a matter of policy. I am not in a position to evaluate the Nation's policy on how much money should be spent on nuclear rocket development at this stage. I just do not know the answer to that question.

Mr. SISK. I appreciate that but I got the impression you felt we would not be able to go into outer space as such—I am speaking now of going into millions of miles—until there is either a program such as you have outlined or something similar where nuclear propulsion is used, that it would not be feasible; is that correct?

Dr. MERKLE. I think I would qualify that statement a bit. You can get to Mars using chemical energy if you want to but it is going to be a very, very inconvenient and costly thing to do.

I had hoped Dr. von Braun would be here to comment on this point because he has studied that matter a little bit.

Fairly extensive schemes are required to get chemical rockets to go to Mars and also back again. Let me put it this way: If you want to get to Mars or Venus at all conveniently, it will be necessary to use nuclear energy.

Mr. SISK. Would you like to be doing some work on this?

Dr. MERKLE. Personally, you mean? Certainly.

Mr. SISK. I am concerned with whether or not we are doing the things that we should be doing in looking ahead. We have heard criticism here because we had not put other programs into being soon enough. I do not want to be responsible for neglecting basic research in this particular field which might put us, let us say, 5 or 20 or 50 years behind. I am concerned with your thinking in the matter because I know you have knowledge of importance.

Dr. MERKLE. Let me answer that statement as follows: I think you have a very fine program at Los Alamos on the heat-exchanger-type rocket. One I have been facetiously calling Old Pokey.

At Livermore you have the program on Pluto, which is a nuclear ramjet. Now a lot of problems of the nuclear ramjet are similar to the problems of Old Pokey. So in a sense the work at Livermore will apply to very high temperature developments, powerplants, be they for ramjet engines or be they for rockets.

So we do not feel that we are entirely out of the picture. At the two Laboratories we have a considerable amount of effort being expended and I think an appropriate amount being expended on the development of reactors for these applications of the Old Pokey type. When I say an appropriate amount, by the way, I assume that the 1959 budget will contain what we all have asked for.

If it does not, then the amount is very inappropriate.

Mr. SISK. Do you feel, or do you have any knowledge, that the Russians may be working on nuclear propulsion?

Dr. MERKLE. That has bothered me a great deal. Everything that went into our studies on Old Pokey was derived from handbooks and whatnot that have been available since 1945. I do not know of any reason why the Russians should not be developing nuclear rockets or ramjet engines of the Old Pokey variety, that is the heat exchanger variety.

On the other hand I have no specific intelligence information that tells me they are. There are some releases that have been made in Russian journals of a popular sort which claim such things are being developed but the releases were technically not very complete and it was difficult to judge whether they were releases that covered up something deeper or whether they were the Sunday supplement type of thing.

Mr. NATCHER. Dr. Merkle, on Monday of this week our chairman, Mr. McCormack, introduced a bill H. R. 11881. This bill provides for research in the problems of life within and outside the earth's atmosphere and for other purposes.

Have you had a chance to read this bill?

Dr. MERKLE. I have not had a chance to read that bill.

Mr. NATCHER. There is one provision in the bill I would like to read to you and ask you how you feel about it. It provides that—

> The Congress further declare that such activity shall be directed by the civilian agency exercising control over aeronautical and space research sponsored by the United States except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations in which case the agency may act in cooperation with or on behalf of the Department of Defense.

Based on your experience with the Atomic Energy Commission, how does that provision sound to you?

Dr. MERKLE. Our relations with the Atomic Energy Commission at Livermore have been excellent. I do not see why an agency patterned in a similar way, no matter how it might be formed, to the Atomic Energy Commission should not work quite well in space development.

Mr. NATCHER. In other words, you feel that such a program as this particular program could be and should be directed by a civilian agency?

Dr. MERKLE. There are advantages to this. I am speaking now of the nuclear rocket-type program. For the chemical rockets there exists already so much hardware developed in the military programs that it is another matter altogether I imagine.

Mr. SISK. Mr. Chairman, I have just one concluding question. Do I understand you to say that the nuclear propulsion method has any particular application at present to the ICBM?

Dr. MERKLE. I made no statement at all about the application of nuclear propulsion to the ICBM.

Mr. SISK. I stand corrected then. I am concerned as to whether there are possibilities in the use of nuclear propulsion in ICBM's. I am also concerned whether this might provide a way of say, leapfrogging some other power in the world today.

Dr. MERKLE. You see, I am very prejudiced and therefore I cannot give you an honest answer to this. As I mentioned before we have at Livermore, Project Pluto. I have a lot of faith in Pluto. I think it will put the ICBM's out of business, but it is not a nuclear rocket.

Mr. SISK. I realize we may all be prejudiced at times, Doctor, but if Congress has some knowledge of the potential that exists, I think that it might be well to do something about appropriations, do something about the changes in these programs.

Dr. MERKLE. It seems to me that it certainly is true if you are talking about liquid propellent rockets, that a nuclear rocket ultimately might be able to outperform a chemical rocket, or do the same job for less money in the ICBM field.

What type of nuclear rocket this would be or when you could get such nuclear rocket I do not know. But the same arguments I used a while ago, having to do with the fact that you can separate the reaction mass from the source of energy, apply also to the nuclear rocket for ICBM's, only not quite so spectacularly as they apply when you wish to go far away from the earth.

Mr. SISK. But you do agree that research might be profitable in this field?

Dr. MERKLE. It might very well be; yes.

Mr. SISK. Thank you.

Mr. FULTON. Is there a limitation on the development in the use of nuclear rockets because of the danger through the discharged materials?

Dr. MERKLE. If you fire nuclear rockets, the least of your worries would be the material that is discharged from the reactor. That is, if you are in a shooting war and you are firing bombs, clean or dirty, the radioactivity dumped into the atmosphere by those weapons will be considerably greater than the amount which can conceivably be put into the atmosphere by any kind of nuclear rocket. From the standpoint of fission fragments and the like, the amount of material that is burned is about a tenth of a percent, or of that order, if you make a calculation just based on energy, not going into the size of rocket or any other classified business, of the fissionable material carried. This is a very modest amount of fissionable material.

I think the way it is commonly said is that any warhead test, for example, at Eniwetok or Nevada, makes considerably more fission fragment release than a nuclear rocket would.

Mr. FULTON. So you see no danger from either the testing of nuclear rockets being added to the current nuclear testing, nor do you see a danger through the practical use of nuclear rockets later?

Dr. MERKLE. As far as increasing the total burden of radioactivity in the earth's atmosphere is concerned I don't see any such danger at all.

The CHAIRMAN. Have you completed your statement, Doctor?

Dr. MERKLE. I believe I have covered all the topics I wish to, so I am open to questions, I guess.

The CHAIRMAN. The members started asking you questions and I did not know whether you had expressed your full thoughts.

Dr. MERKLE. I think I have expressed the thoughts that I brought here today for this purpose: One having to do with where does nuclear energy fit into this picture of space travel, and the other that it will be a long time before you have space travel with nuclear power. We should maintain a uniform program if we expect to get there at all.

I would like to go along with the other two gentlemen who testified today in making very clear that I believe the stability of laboratory programs is exceedingly essential if reasonable progress is to be made most efficiently.

For example, at Livermore we have felt the effects of violent fluctuation in nuclear propulsion programs and those effects were not good. They have cost the programs in question quite a bit of time. The turning off and turning on is not a good way to get laboratory results by able people. In fact, it is a very bad way. So I think that if this committee is interested in seeing the United States maintain a lead in the development of nuclear energy for application to space travel, and for application to bombardment missiles of all sorts, be they ICBM's driven by nuclear energy or be they Plutos—the important thing to do is arrange for a funding over periods like 5 years that will be steady and predictable. Turning such a thing off and turning it on is just simply murder to a group that is doing the work.

Mr. MCDONOUGH. Dr. Merkle, what is the presently known thrust possibility of a nuclear rocket?

Dr. MERKLE. This question of thrust has been kicked around a lot. I would like to make something plain. Thrust in itself does not mean a great deal. It is related to the amount of payload that you can carry. Thrust per unit payload carried is probably the quantity you might like to talk about. A nuclear rocket could have any thrust under the sun. It depends on how big a one you build. That is also true of the chemical rocket. The thrust you can get depends upon how big a one you can build.

Mr. MCDONOUGH. Is it possible that the thrust Russia has is from nuclear power?

Dr. MERKLE. I don't think so. You see the important thing in a high-performance rocket is not just its thrust but the speed at which the exhaust gases are thrown out. There is a relation between the thrust and the power and the specific impulse and it goes like this. Thrust is always equal to twice the power divided by the specific impulse multiplied by gravitational constant. Thrust is equal to twice the power divided by the exhausting velocity of the rocket.

Now if you want to have a system with a very high thrust you can get the thing two ways. One way is to have a very high power, the other way is to have a very low exhausting velocity. But if you do it with a very low exhausting velocity you will have a high thrust all right but your rocket will not go very far, you will run out of fuel in a hurry.

So thrust alone is not the figure that you would like to use.

Mr. MCDONOUGH. What is the ratio of thrust in pounds to payload?

Dr. MERKLE. If you imagine for the moment a system that has a specific impulse of 800 seconds, which is pretty high (it is about twice as high as you can get with super chemicals) then you can put about 30 percent of the launching weight of that machine into payload and structure, which means that you will have 15 percent or so in payload. If that specific impulse was 200 seconds you would have something in the neighborhood of one-twentieth of the launching weight in payload, something of that order.

Mr. McDONOUGH. Now if you had a nuclear-propelled spaceship in operation beyond the atmosphere of the earth, beyond terrestrial gravity——

Dr. MERKLE. There is no such place.

Mr. McDONOUGH. Yes.

Dr. MERKLE. Gravity diminishes inversely like the square of the distance.

Mr. McDONOUGH. But the pull gets less.

Dr. MERKLE. The pull gets less but it does not vanish.

Mr. McDONOUGH. You mean after we get beyond that you get within the gravitational field of another planet.

Dr. MERKLE. The thing that really gets into your hair is the gravitational pull of the sun. You see, after you pull a fair distance away from the earth then you begin to feel the pull of the sun more strongly than the pull of the earth.

Mr. McDONOUGH. Is it possible that such a ship would be drawn into the sun?

Dr. MERKLE. If it did not have power that is what would happen to it.

Mr. McDONOUGH. And it could not go in any other direction?

Dr. MERKLE. No. Unfortunately the sun pulls in all directions pretty uniformly. So you have to be able to fight off the Sun's gravitational field if you wish to go from the Earth to Mars.

Mr. McDONOUGH. Do we know that a nuclear-propelled spaceship will operate efficiently at the maximum distance from the earth, the earth's gravity?

Dr. MERKLE. The gravitational pull of the earth in no way affects the operation of the rocket. All the earth's gravitational field does is sort of reach out and pull back on the whole system.

Mr. McDONOUGH. If you were ready to go, and had all the equipment to go, to Mars, how could you avoid orbiting the earth?

Dr. MERKLE. This statement is a little bit hard for me to understand, the picture you have in your mind.

Mr. McDONOUGH. I mean, if you started off from the earth and you wanted to go directly to Mars, how could you prevent the earth's gravity causing an orbit around the earth, from bringing the ship into an orbit around the earth?

Dr. MERKLE. The way you can prevent that is to keep increasing the velocity of the rocket until it goes where you want to have it go.

Mr. McDONOUGH. That means, then, as you leave the earth you must increase your power and keep on increasing your power?

Dr. MERKLE. No; the power does not increase. Let me put it this way. There are two ways in which you can get an object away from the earth. One way would be to give it a terrific wallop very near the earth. This is what the big chemical rockets do. This is what the Old Pokey scheme would do. You give it such a terrific

wallop that it goes to wherever you want it to go. It keeps going slower and slower as it goes there because of the earth's pull but finally it gets way out to where you want it to be. If you don't do anything about it, it will fall back in toward the sun. If the earth gets in the way, it will run into the earth.

The other way to do the same job is to put a more gradual push on it but keep it on for a long period of time. That is what the ion rocket does. Both schemes result in giving a rather large velocity to the rocket and incidentally when you shut the power off if you are not going fast enough you will fall back into the sun but it is possible to build a velocity so high that you would keep going away from the sun, even so. Escape velocity from the sun if I remember correctly is about 25 miles a second.

Mr. McDONOUGH. Do we know what the gravitational pull of Mars is?

Dr. MERKLE. Yes; indeed.

Mr. McDONOUGH. When this ship comes within the full effect of that gravitational pull, then you have to have a reverse effect?

Dr. MERKLE. Yes; if you wish to make a landing on Mars you would then have to brake as you fall in toward Mars. This is why you carry a lot of extra propellant with you.

Mr. FULTON. On those points of velocity, if you left the earth's surface at sunrise you would then be able to go to the moon with increased velocity and you might then, by leaving the earth's surface at sunset, use the gravitational pull of the sun to get to whatever planet you want; is that right?

Dr. MERKLE. Near the earth the pull of the sun is smaller compared to the pull of the earth so you really cannot take much advantage of that. It is a nuisance to you, not much help.

Mr. FULTON. Once you get away from the earth you could not use the sun's gravitational pull to get to a planet nearer the sun?

Dr. MERKLE. It would change the situation a bit and the sun's gravitational pull helps you on a trip downward to Venus, so to speak; "down" being toward the sun, but it would get in your hair on the way "up" from Venus.

Mr. FULTON. Could I have you compare the nuclear-type rockets and the chemical-type tockets fuelwise to the present fuel systems we have?

For example, take the liquid propellants that require an oxidizer. That is the first stage of the Vanguard. Second, would you compare the fuels that ignite on contact in the second stage of the Vanguard; and third, would you compare them with the solid fuels?

Dr. MERKLE. Unfortunately the specific impulse that we feel that we can achieve with nuclear rocket is classified. So I can't really make a comparison of known chemical performance against speculative nuclear performance and have it mean much for this particular meeting. I can make a sort of general statement.

Mr. FULTON. I would rather not risk classification.

Mr. SISK. I have just two questions. It is my understanding, Dr. Merkle, that Dr. Norris Bradbury made a statement that he felt it would be easier to develop and construct a nuclear-powered rocket or an ICBM than it was to develop the atomic bomb or the hydrogen bomb.

Do you agree?

Dr. MERKLE. You are trying to compare apples and beans, or something, there. It is rather hard to say whether an apple or a bean is hard to digest or something like that.

Mr. SISK. I was curious to know whether you were familiar with Dr. Bradbury's estimate and if so, whether or not you agreed.

Dr. MERKLE. In the first place I am not familiar with the statement. I believe I have heard a rumor here or there. In the second place I do not know in what context he was talking and therefore I don't know why he was trying to make a comparison.

All technological problems are difficult. It is my feeling that they are all equally difficult because people mostly work just as hard as they can, they do what they can do. Both of these things will turn out to be as possible, I believe, as the atomic bomb and the hydrogen bomb.

Mr. SISK. Dr. Merkle, will you comment on the control of thermonuclear energy? I realize it is probably somewhere in the future, but will you comment on the likelihood of it, its asset, the application of it to space travel.

I think Dr. Bradbury at Los Alamos has made some comments on its use in space travel.

Dr. MERKLE. I will make a comment about it. To date nobody has succeeded to my knowledge in obtaining thermonuclear reaction under controlled conditions.

To make estimates as to what the weight of a powerplant that does not exist might be per unit power developed is difficult. In the field of rockets it is terribly important to know what the specific power of any system you propose to use will be.

That is to say, how much horsepower per pound you can get. I have no idea what the thermonuclear systems might look like, if indeed they work at all. I believe Admiral Strauss has made the statement publicly that he thinks it will take at least 20 years to get the thermonuclear business under control.

I see no reason to quibble with that statement.

The CHAIRMAN. Mr. Feldman.

Mr. FELDMAN. Doctor, does the problem of metallurgy in connection with the development of a nuclear power used for rockets have any great importance?

Dr. MERKLE. The problems of materials in general are of crucial importance in the development of nuclear reactors for propulsion purposes, particularly space-propulsion purposes. I think it would be wrong to restrict the field to metallurgy. The field of ceramics is also involved, as well as the field of so-called hard metals or the carbides.

Mr. FELDMAN. Would the problems be similar to those encountered in the development of the *Nautilus*, the atomic submarine?

Dr. MERKLE. I think the problems in materials, where involved in nuclear propulsion for space travel, are more severe than the problem encountered in developing the *Nautilus*.

Mr. FELDMAN. Has not cesium, for example, developed as a result of the *Nautilus* program?

Dr. MERKLE. I would not say so. It has been known for a good many years.

Mr. FELDMAN. But it was developed so it could be used in connection with——

Dr. MERKLE. I think what one is doing here is grasping at an individual element. Let me put it this way. To use nuclear reactors for propulsion purposes will require exceedingly high temperatures, no matter how you do it. The *Nautilus* does not have to develop exceedingly high temperatures in order to be a practical device. What we are faced with in nuclear propulsion for ramjet or nuclear rockets is chemistry that is about as unknown as general inorganic chemistry was unknown in 1800.

Mr. FELDMAN. How about the zirconium technique? Did that not evolve during the time they developed the *Nautilus*?

Dr. MERKLE. There has been a lot of work in zirconium metal and its compounds for reactors, not only for such things as fixed powerplants but also for possible portable ones, largely because zirconium happens to have very low capture cross section for neutrons.

I would not say that zirconium resulted from the *Nautilus*.

Mr. FELDMAN. Would you say the great ability to produce U-235 in this country would give us an advantage over the Soviet Union in nuclear propulsion?

Dr. MERKLE. Since I have no idea what the Soviet Union's reserve of uranium may be I cannot really answer that question.

Mr. FELDMAN. We have more electricity than they have; is that right?

Maybe then we can make more U–235.

Dr. MERKLE. I see what you are driving at. I do not know if that follows either. The important thing is how much ore do you have? If they wish to devote a large electrical capacity to manufacture, I suppose they can.

But I really cannot comment on this subject because I have no knowledge at all of Soviet capacity for electricity or Soviet capacity in uranium.

Mr. FELDMAN. I have no further questions.

The CHAIRMAN. Are there any further questions?

Thank you very much, Doctor. We appreciate your presence.

It has been very helpful and for myself and the committee I express our sincere thanks.

Dr. MERKLE. Thank you very much, Mr. Chairman.

The CHAIRMAN. The committee stands adjourned until tomorrow at 10 o'clock.

(Whereupon, at 5:05 p. m. the committee adjourned, to reconvene at 10 a. m. Wednesday, April 16, 1958.)

ASTRONAUTICS AND SPACE EXPLORATION

WEDNESDAY, APRIL 16, 1958

HOUSE OF REPRESENTATIVES,
SELECT COMMITTEE ON ASTRONAUTICS AND SPACE EXPLORATION,
Washington, D. C.

The committee met, at 10 a. m., pursuant to recess, in the Caucus Room, Old House Office Building, Hon. John W. McCormack (chairman) presiding.

Present: Representatives McCormack (chairman), Brooks, Metcalf, Natcher, Sisk, Arends, McDonough, Fulton, Keating, and Ford.

Present also: George J. Feldman, Director and Chief Counsel.

The CHAIRMAN. The committee will be in order.

The next witness is Lt. Gen. D. L. Putt, Deputy Chief of Staff for Headquarters, United States Air Force.

We are very glad to have you here before us, General Putt. You may proceed.

STATEMENT OF LT. GEN. D. L. PUTT,[4] DEPUTY CHIEF OF STAFF FOR DEVELOPMENT, HEADQUARTERS, UNITED STATES AIR FORCE; ACCOMPANIED BY DR. HUGH L. DRYDEN, DIRECTOR, NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS, AND PAUL G. DEMBLING, GENERAL COUNSEL OF NACA

General PUTT. Thank you, Mr. McCormack.

Mr. Chairman and members of the committee: It certainly is a pleasure for me to appear before your committee today. I am honored that you have seen fit to solicit my views in this important initial phase of your operation.

As I understand the situation, your immediate purpose is to establish a general framework for your overall investigation of space research and exploration and to identify the major problems involved.

Later, I see from your schedule, that you will call Air Force technical experts like General Schriever, who heads up the Air Force ballistic missile and satellite programs, and General Keirn, who is my top staff assistant for nuclear matters.

Likewise, General Boushey for astronautics, and perhaps others like Dr. Strughold from the Air Force Space Medicine Laboratories.

Therefore, I will leave the details to them and keep my remarks in a more general vein.

---

[4] Putt, Donald L(eander), air force officer; born Sugarcreek, O , May 14, 1905; s. Harry Edwin and Lucy Hollis (Preslar) P ; B. S. in elec engring , Carnegie Inst. of Tech., 1928; M. S. in aeronautical engring., Calif. Inst. of Tech , 1938, Air Corps Engring. Sch , 1936–37; m. Margaret Wile Yent, Dec. 27, 1933; 1 son, William Donald. Enlisted July, 1928; commissioned 2d. lieut , 1929; advanced through grades to maj. gen , 1949; stationed with 1st pursuit group, Selfridge Field, Mich , 1929–33; flight test pilot, Wright Field, 1933–36, chief bombardment branch, Engring Div, 1938–45, dep. comdg. gen., Intelligence, Air Materiel Command, 1945–46, dep. chief, engring. div , 1946–48, dir Research and Development, U. S Air Forces, 1948–52; v. comdr., Air Research and Development Command, U. S A. F., 1952–53, comdr , 1953–54; dep. chief of staff, development, Hdqrs USAF, 1954—; dir. tech. services, Air Tech. Service Command, Europe, 1945. Decorated Legion of Merit with Oak Leaf Cluster; Bronze Star Medal with Oak Leaf Cluster; Croix de Guerre with Palm (France). Mem. Inst. of Aero. Scis., Nat. Adv. Com. for Aeronautics, Nat. Inventors Council, Sigma Alpha Epsilon, Tau Beta Pi, Theta Tau, Eta Kappa Nu, Sigma Xi, Scabbard and Blade. Home: Quarters 68, Bolling Air Force Base, Washington. Office: Hdqrs. USAF, Washington 25.

On that basis, I should like to discuss three areas of immediate concern. They are:

1. Reasons why our country should undertake a national space program as a matter of urgency;
2. Logical agencies to manage and be responsible for implementation of our national space program;
3. And some of the space exploration tasks we must place particular emphasis on.

First, why should the United States undertake a national space program with such urgency?

I could not improve on the basic answer laid down by the Scientific Advisory Committee to the President in its document, Introduction to Outer Space.

Dr. Killian's group pointed out it was useful to distinguish among four factors which give importance, urgency, and inevitability to the advancement of space technology.

Foremost among those factors was the compelling urge of man to explore and discover—to go where no one has gone before. This characteristic of man has played an important role in the advancement of civilization since history began.

Now that many of the secrets of earth and its atmosphere have been ferreted out, it is only logical that man would turn to outer space.

Another factor was the opportunity for scientific observation and experimentation. We will learn more about the earth, the solar system, and the universe. Undoubtedly, mankind will benefit from new and amazing discoveries. While all of the benefits to accrue from the exploration of space are not crystal clear at this time—as is the case with any early research, discovery, and exploration—they have consistently paid off in betterment of the human race. I have no doubt but that our efforts in space technology will yield returns as great or greater than many significant explorations of the past.

Still another factor was that of national prestige. If we are to lead the world to peaceful ways, if both our friends and potential foes are to listen with respect, then we must lead not only in industrial, economic, and military strengths, but in science and technology as well.

And, lastly, the defense objectives for the development of space technology were pointed out. Dr. Killian's report pointed out that we wished to be sure that space was not used to endanger our security. It is in this area that I should like to add my thoughts.

It appears most important that our Nation and its allies win and maintain the capability to control space in order to assure the progress and preeminence of free countries everywhere. If liberty, freedom, and justice are to prevail for all peoples, we cannot permit the dominance of space by those who say they will bury the United States.

You will note I have stated that the United States should win and maintain a capability, and I repeat the word capability, to control space.

I do not say that we must exercise control of space, but we must have the capability to do so. There is an important distinction between the two.

We in the military fervently hope that all nations join together in whatever measures need to be taken to insure that space is never used for any but peaceful purposes.

But until international arrangements are made that assure this objective, our possession of the capability to control space would guarantee liberty of the free nations and not deny the anticipated benefits of space to others.

Freedom in space might be considered analogous to freedom of the seas. In the past, when the military capability to control the seas was exercised by peaceful nations, people everywhere profited.

The military capability to control space insures its advantageous use for nonmilitary purposes, which, of course, is our ultimate goal.

Further, I am positive that increased knowledge of space will open a new vista of scientific plenty that will benefit people throughout the world. For example, I should like to mention two military space vehicles which also have beneficial peaceful uses.

The first of these is the reconnaissance satellite for surveillance and mapping the surface of the earth. Eyes in outer space will keep us informed of military movements on the earth's surface. Mapping accuracy will be increased greatly, military targets throughout the world could be plotted for greater accuracy. We would have almost immediate warning of hostile action anywhere on the surface of the earth. This, in turn, would permit much faster reaction on our part.

On the other hand, it could be a powerful instrument for peace in the implementation of any inspection system or "open skies" policy. Further, the reconnaissance satellite should prove a boon to weathermen everywhere.

Thousands of lives and many dollars could be saved by precision forecasts of hurricanes, typhoons, and other severe weather. Worldwide study of the energy imbalances surrounding our earth might provide the first real clues to weather control. Certainly, long-range seasonal forecasts can vastly improve the productivity of resources from the earth.

Even the farmer could benefit from improved weather forecasting resulting from reconnaissance satellites.

The second vehicle with peaceful, as well as military application, is the communications satellite. At present, all transoceanic communication is by costly cable or by shortwave radio, and the latter is often disrupted by solar disturbances.

With the present state of the art, television can be beamed only a few hundred miles and is limited to line-of-sight distances. Several suitably equipped and located satellites could serve as radio and television relay stations, able to receive signals from any point on the earth and relay them either directly or via another satellite to any other point. Solar or nuclear energy power sources could give them useful lives of many years.

Better understanding between the nations of the world has always followed improved communications in all forms.

When we have the added capability to send man to and from these communications satellites for maintenance and perhaps operating purposes, their usefulness will reach a tremendous peak of efficiency. The value of such satellites for long-range military communications purposes are so obvious that I need not dwell on that subject.

As we go farther out into space, it is a certainty that additions to our knowledge will bring forth valuable, and as yet undreamed of, practical applications to man's well being. But the benefits to be

gained through our knowledge and use of space are apt to be dependent upon our ability to control space.

As an airman, I have long since learned that the capability to control the air above the earth's surface permits freedom of movement on the land and seas beneath.

As we progress into space, I feel sure that our capability to control that medium, or selected portions thereof, will assure freedom of movement both on the surface of the earth and through the earth's atmosphere.

Next, let me turn to the area of management and implementation of our national space program.

Too often in our history the solution to new and vexing problems has been to create new organizations that add to the Federal overhead cost, but really do little to alleviate the situation.

At one point in the almost hysterical reactions to Sputniks I and II, it seemed that space technology would somehow be considered an entirely new kind of military and scientific mission. That approach could have had only 1 of 2 results, either a new and fourth military service for all practical purposes and/or new governmental scientific agencies, or fierce competition among existing services and agencies for the space mission responsibility.

But, as is frequently the case, the solution was at hand. Perhaps, because it was so simple, people were reluctant to advance it for consideration.

I am glad to see that reason has prevailed and we have come to the realization that the necessary tools are already at hand in governmental agencies, science, and industry. The real problem is actually one of work selection and coordinated direction. In other words, effective management.

First of all, I feel the Congress is to be congratulated on the forthright manner in which both the House and the Senate have accepted their responsibilities to the American people for space technology. I am confident that this committee, and its counterpart in the Senate, will, at the end of its deliberations, provide the guidance necessary to insure preeminence of the United States in the space world.

The establishment of the Advanced Research Projects Agency in the Department of Defense is a large stride in the direction of adequate military management in the space age. At the same time, the temporary assumption by this agency of our national space program, while proper procedures and responsibilities are worked out in sensible fashion, will help insure that we lose no more time in this race for the conquest of space.

I am sure the ARPA will make valuable future contributions in the vital matters of establishing worthwhile projects, setting priorities, coordinating efforts, and guiding the many participants in these undertakings.

The action, however, that is the most logical to me, is the legislative proposal to the Congress calling for the redesignation of the National Advisory Committee for Aeronautics as the National Aeronautics and Space Agency with a commensurate increase in functions, responsibilities, and authorities. This is the action that I referred to as being at hand, but perhaps so simple that people were reluctant to put forth such a proposal.

The Air Force fully supports this proposal in principle.

It is logical from many viewpoints. The basic charter of the NACA states:

to supervise and direct the scientific study of the problems of flight with a view toward their practical solution.

And in discussing space technology, it should be recognized there is no division, per se, between air and space. For all practical purposes air and space merge, forming a continuous and indivisible field of operations. Thus the NACA already has great responsibility in the astronautics sciences.

There has been and still is evidence of efforts to isolate astronautics and aeronautics. This separation is impractical, if not impossible, and can only lead to confusion.

Any ventures we make into outer space must be based on the foundation or knowledge already accumulated in flight within the sensible atmosphere. Space vehicles of any kind that originate on earth must pass through the atmospheric envelope both on the outward and return journeys.

The NACA has much to offer as a national space agency outside the Defense Department.

First, its more than 40 years of experience and often proved capability cannot be ignored.

For example, most of the airfoils incorporated in the design of all aircraft are NACA developments or refinements. The high lift and relatively low speed airfoils that allowed the United States to become the undisputed world leader in air transport operations were NACA developments.

The laminar flow wing that made the P–51 Mustang the outstanding fighter of World War II must be credited to the NACA. Likewise, the efficiency of many of our current supersonic military aircraft can be attributed, to a large degree, to high speed aerodynamics research by that agency.

For example, the so-called "coke bottle" fuselages of the F–102, the B–58 and other supersonic military aircraft have greatly increased their maximum velocities. These shapes were designed in accordance with NACA-developed "area rule" theory.

Studies and experiments started by the NACA in 1952 have led to the X–15 aircraft which will let man go more than twice as fast and four times as high as he ever has before.

More recently, results obtained by this agency have helped solve the reentry problems for ballistic missile warheads. NACA research has helped prove the feasibility of the boost-glide aircraft—spacecraft hybrids that will be able to orbit the earth many times and reenter the atmosphere at will.

At the same time, this far-looking agency is accomplishing research and experimentation in new means of propulsion; ion, photon, nuclear, and solar, to name a few.

Many of the research facilities needed as basic tools for explorations of outer space are already at hand in the NACA. Facilities worth more than $300 million are now in everyday use. In that respect, the NACA has demonstrated a unique capability to devise, design, and construct new research tools. Their accomplishments in advanced wind-tunnel design is but one of the many examples I could point out.

The NACA employs more than 7,500 people, of whom more than 2,000 possess professional degrees. They are a competent, well-balanced team.

But, perhaps most important, the NACA has established a fine working relationship with the military services, the scientific fraternity, and industry. Its leaders are as respected as the scientific data that result from its research activities. General Doolittle, the Chairman, is an outstanding scientist, military and industrial leader. Dr. Dryden, the Director, is recognized as a practical scientist and effective administrator.

I cannot urge too strongly that the Congress act favorably on proper legislation that will redesignate the National Advisory Committee for Aeronautics as the National Aeronautics and Space Agency and change its mission and responsibilities accordingly.

And, now, let me turn briefly to my last area, a few of the tasks we must concentrate on to insure that the United States not become a second-rate world power in space capability.

Fortunately, we are in a relatively good position today because we can use the ballistic rocket as a basis for initial exploration of space. Recent events, the Russian sputniks and our own Explorers and Vanguard, have driven this fact home.

The ballistic missile programs have contributed in a very concrete sense from the standpoint of hardware that has or is being developed. A tremendous industrial capability and production capability is being built up in many new areas of technology. The airframe, propulsion, and guidance subsystems development and the data which is becoming available as test flights continue make possible a whole gamut of follow-on space projects.

We already are taking advantage of existing technology to prepare for scientific explorations of the moon, perhaps later this year. As you know, the ARPA recently directed both Air Force and Army research and development agencies to conduct a series of "moon shoots." The Thor and Jupiter missiles will be used as basic boosters, with other existing rockets added as additional stages, to send a payload to the vicinity of the moon.

Ballistic-missile technology is also being used as a basis for the military satellite now being built by the Lockheed Aircraft Corp. under Air Force contract.

But I promised earlier that I would not talk too much of hardware now under development; therefore, let me call your attention to two areas in which I feel that greatly increased endeavors are called for.

The first of these is basic and applied research in all of the sciences: Propulsion, materials, electronics, geophysics, biosciences, aero-astro mechanics, and others. That obviously is too broad a field for me to cover in one session; instead, let me use propulsion as an example.

Not only should we accelerate our efforts on the large liquid and solid propellant chemical rockets of the near future, but we must look considerably further ahead.

If we are to eventually conquer the giant distances of even our own solar system, entirely new propulsion systems probably will have to be developed. Spaceships might never be able to carry the enormous quantities of chemical fuel needed to travel freely throughout the solar system.

One new propulsive method undoubtedly will be nuclear, either a nuclear pile using heated fluids or nuclear fusion which can have unlimited range across the solar system. The next step might logically be ion propulsion; that is, obtaining thrust through ejection of a stream of ionized particles. These latter methods are under study now and, theoretically, can supply the propulsion means for extended space travel.

Also under consideration is photon propulsion. This method would propel spaceships by the actual pressure of light particles, but at an extremely slow rate of acceleration.

Those few examples of propulsion developments promise only relatively distant payoffs, timewise. But [that is typical of all basic research. We are proceeding today in astronautics developments on the foundation of technology started 10 or more years ago. If this country is to be the undisputed space technology leader 10 years from now, then we must put more effort into basic and applied research.

As a final item, I should like to touch upon piloted space vehicles.

This committee probably will hear some who cannot visualize the usefulness of manned space vehicles and who honestly believe the ballistic missile and unmanned satellite represent the ultimate in military weapons. I do not share that view.

I want to stress that I cannot conceive that mechanical gadgets alone will ever control space. Rather, man will develop the equipment, launch it, and bring it back. On many occasions, and probably more than we envision now, man will fly the equipment. My point is that man's judgment and unique reasoning ability will always be required to realize maximum effectiveness from any vehicle or weapon system.

Actually, man has already invaded space, at least his mind has, in the form of remote-reporting satellites. But the true conquest of space will come only when man himself flies well beyond the farthest reaches of the sensible atmosphere in vehicles of his own design.

For centuries, man threw or catapulted things through the air, rocks, spears, arrows, bullets, rockets, artillery shells, and other items. But it was not until 1903 when the Wright brothers made the first powered flight in heavier-than-air craft did man really begin to conquer the atmosphere. And then, prophets could not visualize military or commercial uses for the airplane!

Similarly, man will not conquer space until he penetrates it in manned vehicles whose flight paths he can plan and in which he can return at a time and to a place of his own choosing.

In the Air Force, progress toward space has been evolutionary, the natural development of speed, altitude, and sustained flight. These qualities have been our stock in trade throughout the 50 years of Air Force history. We have continually striven to fly faster, higher, and to remain airborne longer.

This evolutionary process which has brought the Air Force to its present high state of development does not change in direction because there are additional challenges in space. Aeronautics and astronautics are closely allied. In fact, astronautics is only a part of aeronautics.

Actually, the Air Force has been penetrating the fringes of space for several years in manned aircraft. Men like Yeager, Everest, Apt, and Kincheloe have been our pioneers in the famous X–1 and X–2 series of aircraft.

Much of the research which the Air Force has been conducting on the ground likewise is designed to place man in space. The Department of Space Medicine was established almost 10 years ago at Randolph Air Force Base, Tex. Physiological experimentation is also being conducted under the auspices of the Aeromedical Laboratory at Wright-Patterson Air Force Base. Volunteers like Colonel Stapp and Major Simons have opened the doors to much valuable knowledge concerned with placing man beyond the earth's atmosphere.

We will have our first quick look at piloted space flight next year when the X–15 begins its long series of tests. However, it should be emphasized that this is a flight into space rather than actual space flight. The pilot will be in space and weightless for several minutes, but it is too short a time to be called true space flight.

A proposed Air Force follow-on project is an extension of the X–15 concept. These are the Dyna-Soar boost-glide vehicles which will be lifted to global orbiting speeds and altitudes and reenter the atmosphere in a manner similar to the X–15. Although both of these vehicles are but one step away from true spacecraft, they still are hybrids, half airplane, half spacecraft.

Very likely, man will first realize true space flight in a manned satellite capsule of some kind. Under the guidance of the Advanced Research Projects Agency, the Air Force now is investigating several proposals for recoverable manned satellites. Manned space flight in this manner is much closer than you think, a certainty within a relatively short time. I believe we should push this project with all possible vigor and at the highest national priority.

In connection with these piloted space vehicles, you may notice that I have not mentioned any specific weapons that would be employed. In that respect, I should like to underscore a thought that appears to have been overlooked by some who question their usefulness. I don't know what kind of weapons man will use in these spacecraft, but I do feel reasonably sure that present-day concepts and weapons will not be married to space-type vehicles.

In fact, it is quite possible that the nuclear warheads of today will be totally obsolete. Undoubtedly, many new equipments and techniques will be developed in conjunction with the space vehicles. It is even possible that some fantastic new device might enable our manned space forces to neutralize or paralyze an aggressor without loss of life or destruction of property.

That seems a highly imaginary possibility now, so much so, in fact, that some knowledgeable individuals will flatly declare it impossible. I could only counsel against the negative approach lest we parallel the 1903 prophets who could see no military use for the airplane, or those in 1941 who refused to believe the power of the atom could be harnessed in a bomb.

America has progressed by following the positive approach to all challenges. It will continue to grow and prosper only if we adhere to that philosophy. We must believe that new scientific discoveries, if properly controlled, always prove of benefit to mankind. We further must accept that new discoveries only result from continuous and widespread exploration, much of which will be fruitless.

There has been exploration since the beginning of mankind, since the beginning of curiosity. Because of the airplane, there are very few secrets on earth with which we are not acquainted. Now, the ex-

ploration by mankind will continue, only in space as well as in other areas.

As a nation we must have both vision and tenacity to be the leader in this new type of exploration.

If we do not expend the thought, the effort, and the money required, then another and more progressive nation will. They will dominate space and they will dominate the world. We must not let it happen by default.

We in the United States can be first. However, to do so, we must not only expend much thought, great effort, and considerable money, but to borrow a thought from Dr. Killian's Space Primer, we must also be very bold in our execution.

Mr. Chairman, that concludes my statement.

The CHAIRMAN. General, I noticed on page 3 of the mimeographed statement you said:

> We in the military fervently hope that all nations join together in whatever measures need be taken to insure that space is never used for any but peaceful purposes

This is a new field that mankind is entering into. It might be termed the space age for descriptive purposes. Before any 1 or 2 countries make sharp advances, with the competitive situation that might develop, and before practical advances are made where they can be utilized for destructive purposes, we have to face the fact immediately in front of us, that now is the time to have the nations of the world enter into an agreement that might reasonably insure that the advances made will be used only for peaceful purposes.

General PUTT. Mr. Chairman, of course, in any situation of this nature where one is to sit around a conference table and work toward world peace, one must be careful in negotiations that we were in a proper position to insure that the results of such international agreements will go in a way that will best benefit mankind.

While I have not thought this through to its conclusions, it would seem to me that very careful thought would have to be given to the time when such advances might be made for an international conference and also as to where we, ourselves, stood at the particular time.

The question is a good point and it will take a lot of diplomacy and judgment to know when to proceed along such a course of action, but it would seem to me that however we might arrive at international agreements, that at least it is a good objective to be working toward.

The CHAIRMAN. Of course, my question was a very broad one and included the thoughts in my own mind and some of the thoughts you had. These do not involve the question of not proceeding because you could not stop that anyway.

General PUTT. That is right.

The CHAIRMAN. But the agreement for the uses. It seems that there might be a probability of greater success on the international level, if any can be obtained, before the fact rather than after the fact.

General PUTT. Yes.

Our thinking here was sort of a continuation of the efforts of our President to at least have greater cooperation among our friends and nations in scientific and technical fields, and it seemed to us there would be an advantage at the proper time, under proper circumstances, where space technology could be included in that kind of thinking

The CHAIRMAN. Your statement conveyed to me the fact that you

had it prominently in mind, otherwise you would not have included it in your statement. It was stressed so effectively that it conveyed to me that it was a mature thought on your part.

That is what caused me to make the inquiry, not that activities should not be undertaken by our own country but is there not a better possibility for discussion as to future uses for peace purposes before the fact than what might be termed after the fact?

General PUTT. That is correct.

The CHAIRMAN. Mr. Brooks, do you have any questions?

Mr. BROOKS. General, I think you always present the subject matter forcefully. You have done it in this case and with clarity too.

I want to ask you a few questions.

You end your statement with a paragraph which leaves no doubt in my mind that the nation which dominates space is going to dominate the world. That is true, is it not?

General PUTT. That is certainly the way I feel; yes, sir.

Mr. BROOKS. And we have no choice but to move forward in the development of space discoveries?

General PUTT. I can see no alternative.

Mr. BROOKS. If we do not, we can assume that Russia will move forward and preempt space ahead of us, in which case we may have no assurance that it will be peacefully used.

General PUTT. That is correct.

Mr. BROOKS. If we move forward and make the discoveries and make the developments, we can then control the use of space so that it will be peacefully used for the world, for this earth.

General PUTT. I certainly subscribe to that.

Mr. BROOKS. I want to get this straight in my mind. There is another thing that I would like to know.

How high do you, or does the Air Force, consider it is necessary to go in order to reach outer space? What is your definition of outer space now?

General PUTT. This is a relative question that is occupying the thoughts of a lot of scientific, as well as a lot of legal people, as to where the atmosphere ends and space starts.

One of the, in my mind, less accurate statements, is that the atmosphere extends out to that point where vehicles are airborne, but I am not so sure that that is a practical division.

As I said, in my statement, I do not think that there is a dividing line between aeronautics and astronautics, between the sensible atmosphere and space.

I might use the analogy of the sea. From the surface of the sea to the bottom of the ocean there is a great change in density.

From the bottom of the ocean to right on the surface, we never think of there being a layer of the sea that has something different about it than another layer of the sea.

Maybe, from the legal standpoint, this is pretty naive and something else has to be done. But from a scientific and technical standpoint, I do not feel that one can make a division between the atmosphere and space.

Certainly there are some new sciences and some new problems that enter as one goes farther into space, but we just consider it a normal extension into a visible area of operations.

Mr. Brooks. General, if you were going to just set an arbitrary limit to the inner space as contrasted to outer space, what would you say was an arbitrary limit dividing the two?

If the chairman has no objection, we shall be glad to have Dr. Dryden answer.

Dr. Dryden. I agree with what General Putt says, that the boundary between the atmosphere and space is entirely arbitrary.

You have an airplane weighing 20 pounds per square foot. Atmosphere is where that airplane can fly level. But you immediately have it fly higher when you have an airplane weighing 3 pounds per square foot.

Generally speaking, we say if we can get a body up above 200 miles there is very little influence, very small influence of the air on its motions.

So you might think that 200 miles is an arbitrary limit or if you like, you can come down to a very much lower value.

Now, this designation of inner and outer space has crept in. I confess I do not know what it means. At present we are thinking in terms of travel within the solar system, mainly because of the fact that the little extrapolation we do if we try to go outside the nearest star, which is 4 light years away, the same people could not come back.

Someone facetiously suggested you would have to send out a group of families and hope that the children would come back.

So normally we think of the reasonable space within the solar system.

Our immediate objectives are going out, of course, in the general neighborhood of the moon. Later on we hope to get out in the neighborhood of Mars and Venus.

But this is extrapolated on present experience so far. I don't know what to call inner and what to call outer.

Mr. Brooks. The reason I asked that question is because General Putt has referred to the fact that domination and control of space is control of the earth.

Then what do we mean by control of space there? If we are hazy as to the beginning of space there and we are bound to be hazy to some extent, just how far up do you mean?

Dr. Dryden. I do not want to differ with my distinguished colleague or some distinguished Senators. I think for the near future, the people who control sites on the ground are going to control the space they get into in the immediate future.

Only at some later date will it be appropriate to perhaps reverse this process. Actually, presumably we are interested in things on the earth anyway, and we are interested in space in the sense that you have been talking as a possible source of harm to us here on the ground.

Now, the further away the object is in space, the longer it takes to get to the earth and to the ground to do us harm. So in a way, you might say that space operations which are at the moment confined to the neighborhood of Mars are not putting any particular threat to us here on earth; whereas, the present ballistic missiles which go up just a short distance in space convey much more of a threat.

Mr. Brooks. Well, we will put it this way. General Putt said that the reconnaissance satellites could circle the earth and be a threat. Is that correct?

Dr. Dryden. A threat to your privacy.

Mr. BROOKS. Our privacy and consequently to the peace of the world.

Dr. DRYDEN. It is like people looking in your back doors and your factories.

Mr. BROOKS. How high would that be?

General PUTT. That would be in the order of 300 miles.

Mr. BROOKS. And then weather forecasts and weather control, you envisage the actual control of weather, do you?

General PUTT. We do not say that this can be done. It could turn out to be a possibility.

Mr. BROOKS. That would bring you up pretty high, would it not, above 60,000 feet, for that purpose?

General PUTT. That is true.

I might draw an answer, by analogy, to your question of how high one must go to control space. I think we can draw an analogy just from our aeronautical experience itself.

We have always strived to try to fly higher and higher. One could control the atmosphere by just being able to fly a little bit higher than the other fellow. So I think the same thing will occur in space.

It is always going to be a race who can get higher and farther out. So that control of space could start initially at a relatively short distance away from the surface of the earth.

Mr. BROOKS. That is more my thought. How low can you come in a space world and still dominate the earth? Radio and television would mean remote use of space areas, would it not?

General PUTT. I am sorry; I did not understand the question.

Mr. BROOKS. You referred to communications, radio and television, and to satellites providing communications. When you referred to the use of radio for that purpose, that would be for remote areas, would it not?

General PUTT. It would be for remote areas. Also, it would be a great aid to just global communications from point to point on the surface of the earth.

We are now limited by the natural phenomena, by the curvature of the earth, line-of-sight electrical horizon which prevents us from communicating directly from one point of the earth to the other where they are separated by great distances. By having satellites used as relay stations, one can communicate directly on a continuous basis.

Mr. BROOKS. In other words, send the wave up and let it bounce back.

General PUTT. That is correct. We could have television broadcasts direct from here to Europe, for instance, instead of being limited to just this line-of-sight distance.

Mr. BROOKS. Do you know what satellite it is going to bounce off when you send it up?

General PUTT. Surely.

Mr. BROOKS. I want to ask you about NACA. I helped to frame legislation organizing NACA.

Is it adaptable to the purposes which you have in mind?

General PUTT. Absolutely; in fact, I think it is really the best practical solution that we could find and I think they are eminently adaptable to the work in space because it is just an extension of the work that they have been doing for years.

Mr. BROOKS. Are the grades of scientists that we have in NACA comparable to any scientists in the world?

General PUTT. I think they are.

Mr. BROOKS. Do you have any particular criticism about the background and education of these men or their shortcomings?

General PUTT. No, I do not. Of course, you can always say, gentlemen, we wish we had better.

Mr. BROOKS. You would not be in the Air Force if you did not want something better, would you?

General PUTT. That is correct. We are never happy. We are never satisfied.

But I think, everything considered, that NACA has been eminently successful in organizing and acquiring a real outstanding team and group of scientific and technical people.

Mr. BROOKS. I think they could carry it on even in this era that you are looking forward to.

General PUTT. Yes, sir.

Mr. BROOKS. That is all, Mr. Chairman.

The CHAIRMAN. Mr. Natcher?

Mr. NATCHER. General, in your statement you stress the importance of controlling space in order to preserve our way of life, and you further point out the fact that if this country is to be the undisputed leader 10 years from now, we must put more effort into basic and applied research.

General, I certainly agree with those statements. How do you feel about a crash program?

General PUTT. Frankly, I think that unless circumstances dictate that one's only alternative is to go into a crash program, that they are not the way to do the job.

It takes more money; it takes more people; it takes more in the way of facilities to insure a successful crash program.

You have to cover your bets in many ways and you have duplication that otherwise would not have to be engaged in if one proceeds on a leisurely, an orderly, and vigorous program which is sustained and constant and meets the needs.

I think crash programs are wasteful. We get ourselves into situations where sometimes this becomes absolutely necessary, but I do not think it is the way to run any kind of program and particularly a scientific program.

Mr. NATCHER. General, would you agree that at least we should step up our present program from the standpoint of more appropriations for those programs that we are sure about at the present time?

General PUTT. I do.

Mr. NATCHER. General, why not just meet this problem head on and just face the facts. You agree that the Manhattan project was a success and necessary at the time. We now know what to expect to a certain extent as far as outer space control is concerned.

Why not just meet the problem now and move on? Do you feel, General, that we are proceeding fast enough at the present time?

General PUTT. I would like to see us proceeding somewhat faster than we are. I think we should do this with good judgment and be sure that we are on the right track.

One of the real difficult problems that I think faces all of us in the management and administration of our space technology programs

is that suddenly with the advent of large rocket motors that make it possible to get out into space, we have opened up such a broad vista of things that could be done, that the real management job now is that of exercising good judgment in selection and doing the things that are proper and not just scatter our shots all over the place.

We could spend billions of dollars on interesting projects. We could disperse our effort.

I think to get on and to make the most of the resources and people that we have, we must be very selective and do the important things and do them first.

Mr. NATCHER. General, the people in this country, I feel, have gotten a little complacent since Explorer No. 3 has been placed in orbit. Do you agree that the day for this type of complacency has passed?

General PUTT. It certainly has, long passed.

Mr. NATCHER. General, how do you feel about science receiving a position in the Cabinet?

General PUTT. Well, I am afraid I have not given enough thought to the exact manner in which this country should organize to give due account to the contributions that science has made, or will, of necessity, make in the future.

But I do feel that some greater emphasis, some greater cognizance of the tremendous role that science is going to play in the future, science and technology, in the future advancement and development of our country, certainly wants some steps other than we have taken in the past.

Mr. NATCHER. General, I want to ask you just one particular question, which is technical insofar as I personally am concerned.

How close to the earth can a satellite be put into orbit?

General PUTT. I think one can put a satellite into orbit at about 100 miles, something of that order.

However, the duration, the time that it will stay in orbit, decreases as one gets closer to the earth's atmosphere where you have the atmospheric drag to slow it down.

It has to maintain its speed to maintain a given distance from the earth.

Mr. NATCHER. Thank you, General.

I want to thank you further for the fine statement you have made to this committee.

General PUTT. Thank you.

The CHAIRMAN. Mr. Metcalf.

Mr. METCALF. General, Mr. Brooks raised a question in my mind. Suppose some foreign government sent a low-flying reconnaissance plane over the United States to map the various areas of our country. What would the Air Force do about it?

General PUTT. How low is low in your mind?

Mr. METCALF. Say 2,000 feet.

General PUTT. We would shoot him down.

Mr. METCALF. Suppose they send a satellite with television cameras over the same area, mapping, reconnoitering, and sending information back to that same foreign government, what does the Air Force propose to do about it?

General PUTT. At satellite altitude, sir?

Mr. METCALF. Yes.

General PUTT. There is not much we can do right now.

Mr. METCALF. The question is whether you cannot do anything, or you are not going to do anything. You do not believe there is authority to do anything?

General PUTT. We would if we could, and we think there are some things that can be done if we get along with it.

Mr. METCALF. Then does that not bring up right now the necessity to have some international agreements as to what we are going to do with these satellites in order to carry out your proposal that we join together for peaceful purposes for the use of space?

General PUTT. That certainly could be one approach to the problem.

Mr. METCALF. Because, at this time, the air forces of other governments are unable to do anything about this reconnaissance of their country by means of satellites in orbit?

General PUTT. That is right.

It seems to me that at the present time international agreements are the only way that one can control the use of satellites.

Mr. METCALF. Then actually, the question of where space begins and where it ends is a question of whether the Air Force can shoot down a reconnaissance plane?

General PUTT. That might be one way of defining it.

Mr. METCALF. That is all, Mr. Chairman.

The CHAIRMAN. Mr. Arends?

Mr. ARENDS. First, may I say I am pleased to see you here before the committee. I had the pleasure of listening to you on several occasions on the Armed Services Committee when you brought your presentation before that committee.

I note here this morning that you are appearing still as a Deputy Chief of Staff for Development within the Air Force.

General PUTT. That is correct.

Mr. ARENDS. Somewhere along the line I saw a note you were going to retire someplace, I am sorry to say, because I recognize in you a man of ability and I was hoping you could remain on the job.

Let me ask you this very simple question which was prompted by the gentleman from Montana a moment ago, as to the impossibility of doing anything should the satellite be rushing over the United States for a purpose that we could not do anything about. I think the other side of the coin is the fact that while they are doing that, we likewise would be doing something.

General PUTT. That is correct.

Mr. ARENDS. So I think we must not let ourselves get into a position of defeatism. There must be recognition of the capabilities we have to do the job in the event somebody tries to do that kind of job to us.

General PUTT. That is correct. The major countermeasure race always goes on in almost any new field of endeavor.

I can assure you that we have been doing a lot of thinking about the antisatellite satellite.

Mr. ARENDS. Because I know what you have in mind and what you are able to do might I just ask this question merely as a matter to put into the record again: Whether we are moving fast enough, whether there is something more that Congress in its responsibility should do to expedite a program one way or another, whether it is money, whether we are hamstringting you, your department, in any way in moving ahead as expeditiously as maybe you feel you should?

General PUTT. Of course, there are a lot of factors that have to be taken into account, our entire economy and the other responsibilities of the Nation.

Purely from a technical and scientific standpoint, I think there are things that could be done, a greater emphasis, requiring more money, more facilities.

There is a question of balance between what we can afford to do there and what we can afford to do in the other necessary areas.

But purely from the technical standpoint I think there are things and areas in which we could move a little faster. Whether this is true in the overall, the people have to make the decisions at the highest level.

Whether this is a proper balance, I am not in a position to say.

Mr. ARENDS. That, General, is very important. In all these matters such as this, there must be balance and that is where our responsibility comes in, to see that there is balance. This balance must be maintained.

I think you recognize now, and I hope you do, and the country recognizes, that there is an awareness on the part of Congress and you people that have responsibility in moving ahead on the program, that there is awareness to move as fast as we can, doing the kind of job that is well done when we finish.

General PUTT. That is correct.

Mr. ARENDS. Thank you.

The CHAIRMAN. Mr McDonough.

Mr. MCDONOUGH. General Putt, I was interested in your modest attempt to define outer space and the question of dominating that area by one nation or another. Can we not assume at the present time, with the United States not contesting Russia when they send up a satellite into outer space, it flew over the United States the same as it did the other countries, and Russia not contesting the United States when we put up a satellite, that there is up to the present time without any international agreement a common agreement that outer space is like the open seas, a highway for all nations to use?

Then can we not assume that if the question of domination is brought into the picture at the present time, we are dominating outer space because we have three satellites in orbit and they have none at the present time.

In other words, to establish ourselves in outer space like we might have established ourselves in discovering a new country, you have to go there and occupy it and be there on the ground and fight off anyone that may contest your position.

So that we are in a more favorable position right now with three satellites up than Russia is.

Of course, this committee will undoubtedly go into the question of what is our legal status and at what elevation, as far as the United States is concerned, and that puts a question in my mind. In the revolutions of the earth we cannot stay in one position because we are moving at the time, therefore how are we going to take a band of area around the atmosphere, say it is legal territory around the United States, and say that the enemy cannot come in.

I suppose that the question of establishing our legal right in international agreement is something that is more or less up to—I do not know what agency of the Government, the State Department, or who would decide the question, but it is one that we will have to consider.

Now, insofar as the environment in which man can live and in which the vehicle that he operates can live, is that not a reasonable limit for inner space?

General PUTT. From a technical standpoint it seems to me that if we can provide the environment for the man to live at, say, a hundred, or 200 miles above the earth, at the moment I do not see that it is much more difficult for him to carry that environment still higher.

Certainly you will run into problems when one gets close to the sun, but in normal space I think one could operate.

If you can operate at 100 or 200 miles, you can operate at a thousnad miles, for instance.

Mr. MCDONOUGH. Did we learn anything from Farside except the fact that we shot a rocket to a high elevation? Did we obtain any information from that outside of the fact that we shot it up to a high elevation?

General PUTT. Yes. I think one acquires more information as one goes higher, but as the elements change, we learn something about the temperatures that prevailed at different altitudes. It is not a continuous or constant temperature.

Cosmic rays vary. So that the higher we go, the farther out we go, we find new information and knowledge.

Mr. MCDONOUGH. Farside has gone to a higher elevation than any of our satellites?

General PUTT. Yes, it has.

Mr. MCDONOUGH. It is estimated at 6,000 miles; is that correct?

General PUTT. No, I think our final figures were 2,800.

Mr. MCDONOUGH. There were attempts also to shoot small pellets to the moon. Did we ever find out whether we hit it, or not?

General PUTT. I don't think we know.

Mr. MCDONOUGH. You say the flight of the X–15 would not be a space flight, it would be merely to penetrate space.

Is not the X–15 equipped to fly in outer space?

Dr. DRYDEN. Mr. Chairman, it would be something like a fish jumping out of water. It has a rocket motor which will propel it to high altitudes, to positions where it cannot fly in the normal sense, because there is no air. It will then fall back to an elevation where there is enough air to support it.

So the space flight of the X–15 will be this type of thing like a fish jumping out of water into the air and coming back in again.

Mr. MCDONOUGH. In other words, we are not building a space flight ship.

Dr. DRYDEN. The X–15 was built as a research airplane to study the problems that you have in space flight.

For example, to control the attitude. If you just let the airplane come out and fall back, you get into great trouble. You must turn it over so that it comes back in a normal fashion.

This requires the use of rocket-type controls. We are at present flying such controls on one of the X–1 airplanes to work out some of the problems before we fly the X–15.

The same way in heating. As you probably know there is no trick to put a man in space. Anybody who will take the place of the nose cone on one of the missiles fired at Canaveral will be ejected into space. This is a relative part of the problem.

The X–15 is studying this problem of getting back without burning that airplane up.

Mr. McDONOUGH. Why is an 18,000-mile speed the established speed for a satellite to get into orbit?

Dr. DRYDEN. A satellite is in the position of falling all the time, but just enough to keep up with the curvature of the surface of the earth.

Now, the speed that you have to go so that it only falls at the rate dictated by the curvature of the earth is roughly 18,000 miles an hour. You cannot fly a satellite at any other speed.

If the speed is higher, it will go out into an elliptical orbit. The higher the speed, the greater the elliptical orbit. The slower the speed, it comes into the atmosphere.

General PUTT. Mr. McDonough, the X–15 is a joint Navy-Air Force-NACA project. NACA has the technical direction of the project.

With Dr. Dryden here, I thought it more appropriate that he answer that question.

Mr. McDONOUGH. I appreciate that.

What is the next step beyond the X–15 and is it under consideration at the present time?

General PUTT. In terms of manned vehicles, it is the Dyna-Soar. This is a hybrid aircraft that will operate in space and will also handle and operate very much like a conventional airplane within the atmosphere. It will attain almost satellite speeds.

It combines the dynamic forces of its speed while circling the earth along with a form of soaring. That is where it gets its name of Dyna-Soar, a combination of the dynamic forces and soaring flight.

In effect, it comes back into the atmosphere a little like a glider, except that it has some power.

Mr. McDONOUGH. At what stage is that in or is that classified?

General PUTT. Let us just say it is under development.

Mr. McDONOUGH. As far as the X–15 is concerned, there is only one that we are building at the present time?

General PUTT. There are three actual articles to be used in the complete test program.

Mr. McDONOUGH. They are three different types of ships?

General PUTT. They are all the same. We find that it is real good to have more than one airplane in any kind of a test program because if something happens to one, then you have to go back and start over again and you lose a lot of time.

Mr. McDONOUGH. When Dr. von Braun was before the committee yesterday he said he was prepared, and he could within a year, build a Redstone and provide a man-contained capsule in the nose and shoot him to the moon, but he was not authorized to proceed.

General PUTT. Not to the moon.

Mr. McDONOUGH. I mean into outer space and to return.

General PUTT. It was just a ballistic ride, tossing him out and coming back. In a sense it is the same thing as the X15, although it probably would go higher and the man, I guess, will be in space just about as long.

Mr. McDONOUGH. If he had the equipment on board to observe and to record some of the conditions up there he would go higher than the X–15 and, therefore, give us more information. But he said he was not authorized to proceed.

Do you know why he was not authorized to proceed?

General PUTT. No, I do not. The Air Force, likewise, has a program somewhat similar to that, a little different in scope.

Dr. DRYDEN. May I step in where angels fear to tread?

I feel there are something like 200 projects to put a man in space originating with various groups in the United States. They range all the way from tossing a man up in the air and letting him come back—which, to my mind, is about the same technical value as the circus stunt of shooting the young lady from the gun—to projects where he remains in the satellite for several orbits.

Now, the great problem of the people concerned with this, and I am glad that I do not at present, at least, have the responsibility, is to pick which ones of these 200 projects is to be supported.

That is all.

The CHAIRMAN. Mr. Fulton?

Mr. FULTON. We are glad to have you here, General. I am sorry to know that you are retiring. Are you not under age for retirement?

General PUTT. I believe not. From the standpoint of compulsory retirement for age, you are correct. However, I have completed 30 years of service.

Mr. FULTON. There is some good yet and why do you not stay in? Are you leaving because of any possible holdback by the Air Force on any of your ideas and you might get a broader field outside to express them?

General PUTT. Absolutely not. I am not retiring because I am angry with anyone or in protest of anything.

Mr. FULTON. But looking for a broader field? I did not put the word "angry" into that.

General PUTT. Not necessarily looking for a broader field. I do not know of any particular industry, or position that one might hold, that gives one the opportunity to look as broadly as does the position I hold in the Air Force.

Mr. FULTON. I believe the Congress has the policy of trying to encourage the young fellows with ability to remain with the Air Force.

General PUTT. That might be an element in my retiring so that the youngsters can take over.

Mr. FULTON. We think you are young enough and competent enough so that we would like you to stay.

Let us go further. The problem comes up with the development of the million-pound-thrust engine. Are you familiar with that and the effort to try to obtain a million-pound-thrust engine in the near future?

General PUTT. Yes, sir.

Mr. FULTON. You also know that to date, on studies, the amount spent has been about a half million dollars. Is that not right?

General PUTT. That is approximately correct.

Mr. FULTON. What would your estimate be of the total cost of getting a 1-million-pound engine, something between $40 million and $200 million?

General PUTT. Let me check our records here to see what it is.

Mr. FULTON. I am only a Naval Reserve officer. What is your estimate in general figures, round terms? Is that the area of magnitude that you would likewise estimate?

General PUTT. It is probably in the order of two hundred and fifty to four hundred or five hundred million dollars.

Mr. FULTON. So that it is between two hundred and fifty and five hundred million dollars to make the program. Then under your estimates, at the present rate of expenditure and study by ARPA, it would take between five hundred and a thousand years?

General PUTT. If we maintain the constant rate.

Mr. FULTON. Then what do you suggest? Do you not suggest a tremendously increased program, as I do, which would be somewhat in the nature of a crash program, so that we get there before Russia does?

General PUTT. Certainly we would not recommend retaining the present pace. All research and development projects start out at a relatively low level and, if they proceed normally, the rates of expenditure go up quite rapidly.

Mr. FULTON. In order to have a million-pound-thrust engine developed in 3 years at your lowest estimate of $250 million, we would have to start out with fifty to sixty to seventy million dollars a year in the program right away, would we not?

General PUTT. That is too much for the first year.

Mr. FULTON. We would have to take a tremendous step forward above $500,000, would we not?

General PUTT. Yes.

Mr. FULTON. So it would be up to fifteen, twenty, thirty million dollars for the single project of a million-pound-thrust engine?

General PUTT. That is right.

Mr. FULTON. On the electronics signaling devices that you speak of, by electronic bounce we could monitor and keep under surveillance every part of the world, could we not?

General PUTT. That is right.

Mr. FULTON. So that within a few months, if we would get satellites into space or even use the satellites that are already there, we could do some pretty good work on seeing just where the military buildup might be anywhere in the world.

General PUTT. We could not use the ones we have there now, but we could put others up to do the pioneering work.

Mr. FULTON. And we are able to get bounce off the moon; are we not?

General PUTT. Yes.

Mr. FULTON. So that actually, without any earthmade satellites at all, if we put the pressure on and make investigations we could certainly come up with a comprehensive monitoring system to assure United States security at the time?

General PUTT. Bouncing signals off the moon would not give us reconnaissance.

Mr. FULTON. Is there not some difference of opinion in the forces that it can be done?

General PUTT. None that I know of.

Mr. FULTON. Let us move into this photon vehicle. Do you think that a photon-powered vehicle is in the realm of practicality at any time, or within the foreseeable future?

General PUTT. I would not at this time say that it was within the realm of practicality.

Mr. FULTON. Dr. Merkle yesterday, when I asked the question, dismissed it as something that there should not be studies on and I notice in your statement this morning you are making studies on it. Why do you disagree?

General PUTT. I was not aware of his feelings on this. I hold the view that if there is any possibility of an idea working, one at least must explore it to the extent to insure that either it has or it has not got any promise.

So if there is a body of scientific thought that feels that there is some promise there, I think we ought to pursue it to the point where we determine there is or there is not.

Mr. FULTON. So you would recommend a testing mission really, to see if there is any practical basis and have basic scientific research on photons?

General PUTT. There is a lot that has to be done, and can be done, before one really starts testing. There is a lot of theoretical work that has to be done.

At that stage it is sometimes possible to determine whether it is worthwhile to go on, or not.

Mr. FULTON. But you are not leaving out of consideration of any military or weapons-vehicle program a basic research program on photon-powered vehicles at the present time?

General PUTT. It certainly is in the basic research stage. We certainly would not even be thinking of a military-weapons system that was so propelled at this point.

Mr. FULTON. But you would continue such studies, would you not?

General PUTT. If the basic research indicated it was going to be something that might be feasible and practical, why, then, we would want to at least study the possibility of its application to a military weapon.

Mr. FULTON. I am a member of the House Foreign Affairs Committee, so your comments on the freedom of space interested me. If we put it in its historical background we come to the statements by Grotius, that it was a Mare Liberum, freedom of the sea.

Then we have John Selden, an Englishman who, in 1635, came up with a book "The Dominion of the Seas." That was the beginning or the crystallization of British policy for quite a number of years.

Now, that brings you to a logical dilemma. When you speak of the freedom of space, are you a follower of Grotius, or are you a follower of John Selden, who held that the British Navy should have dominion of the seas for the benefit of nations of like mind and their allies?

Are you saying to us here on this committee that we should have the conquest of space in order to obtain dominion of space, having the power to control it by the United States and its allies, to the exclusion of another power or group of powers?

You see, it brings you to the historic perspective that you must decide whether we will again repeat history in space.

Are we really talking of the freedom of the seas? I can give you one more comment.

We tried in the United States to get away from that sort of dilemma in 1899 with other nations when we were participants in the first Hague Conference. We then tried again in 1907 to expand it without too much success.

The question is: Shall we proceed on the order of a Hague Conference and possibly suggest to the President of the United States that at the Summit Conference he take up with Russia and our NATO allies, the setting up of a Hague-type conference to deal with outer space so that we would have a space assembly similar to the kind that we tried to develop before World War I?

Actually, at the second Hague Conference it was Russia that issued the invitation and we accepted it.

So there is a historic parallel there.

As you may remember, too, there might be set up a commission of inquiry as there was under the Hague Conference of 1907, that we in outer space could have an inquiring commission that made no decisions, that met together on these knotty problems that might involve serious disputes.

Now, which one of these three courses should we take? Do you think we should take Grotius' approach that it is free to everybody, and as Mr. McDonough of California suggested, nobody make any complaints, just leave it open until something happens?

Another one is the theory of John Selden, of Britain, that we in the United States have dominion of space as far out as we can get it and then get into a race for space.

Or, thirdly, do you want it on the order of the United States calling a space conference similar to the Hague-type convention?

Your statement is not clear on the first two, and I am suggesting the third one to you for your consideration.

General PUTT. Mr. Fulton, I am not enough of a student of history in this regard to, I think, answer your question very well.

Mr. FULTON. May I ask it simply, then?

Do you agree that there should be freedom of space with everybody and every nation doing what they want until somebody tries to stop them, just leave it open? Do you agree with that?

General PUTT. I can only draw from my own experience in answering that.

We have seen the type of the freedom of the seas we now have. We have seen how it operates.

Mr. FULTON. Our Nation and the British nation cover 90 percent of the oceans and seas and control them. Is that what you want?

Mr. MCDONOUGH. That we have use of.

Mr. FULTON. That we have dominion of.

General PUTT. I would not think that we have dominion of it. We have the capability or we hope we have the capability of controlling the seas in the event somebody attempts to do something that we do not like. It seemed to me that maybe there is something wrong with the direct application of the analogy, but it would seem to me that what I am thinking of is something in the order of that as far as space is concerned.

Mr. FULTON. So you would favor John Selden on the power to control and obtain dominion, if necessary?

The CHAIRMAN. I do not think he said he would favor anybody.

Why do we not have your theory, then we would have the Fulton program, too?

General PUTT. This is really getting way out of my area of competence.

Mr. FULTON. All right. I recommend to the President that he take up at the Summit Conference and propose a third-type Hague Conference for dealing with the problems of outer space, and also request that a commission of inquiry be set up to handle these problems that may come up, without the power of decision, but with the power to inquire internationally to prevent disputes coming up.

Mr. MCDONOUGH. Will you yield at that point?

Mr. FULTON. I am through.

Mr. MCDONOUGH. Nobody has raised the question internationally up to now.

The CHAIRMAN. Well, I did slightly, there. I assure you I had it in mind, but go ahead.

Mr. MCDONOUGH. Since it has not become an international question and both Russia and the United States have used the space we are talking about, both nations, no other nations have gotten up there yet, the problem now is, I would say, that we ought to let sleeping dogs lie until somebody makes the point.

Mr. FULTON. May I make a short comment here?

There is a fine presentment. Here is the Grotius theory; the Selden theory with the General, and Hague conference with Fulton. We all disagree. What does the chairman say?

The CHAIRMAN. Might I suggest, and it is the first time that the Chair has undertaken to make a suggestion to the members, that we ask questions of the witnesses. Sometimes a little outer space might be necessary in connection with the question, but confine the questions to the witnesses, the questions that interest the different members.

I am going to read Grotius. I will put my mind way out in the dim past so as to familiarize myself with it.

Mr. MCDONOUGH. To expound on what you have just said, we cannot expect the Deputy Chief of the Air Force to come here as a legal space lawyer, an expert on such laws.

The CHAIRMAN. I would not say he was not qualified, but he would probably hesitate to enter into that field.

Mr. FULTON. Might I suggest that when the good General suggests that we dominate and get into a race for space as far out as you can get in order to fight the next war there with some sort of military weaponry, maybe some of us on the Foreign Affairs Committee want to know what kind of legal vehicle you are drawing.

The CHAIRMAN. Mr. Keating.

Mr. KEATING. General Putt, I would like to pursue for a moment your observation on page 7, and elsewhere in your statement, where you said in substance that there was no essential difference between aeronautics and astronautics, or between outer space and inner space.

That is perhaps an oversimplification, but that is the impression I gained. Is it not a fact that the physical properties and elements of what is generally called outer space are completely different from the atmosphere of the earth?

In other words, what I am getting at is that there is no oxygen out there, is there?

General PUTT. That is correct. The problem here is one of change. You start at the surface of the earth. There is a lot of oxygen and atmospheric pressure.

As you keep going out it becomes less and less and less. In the same way the other gaseous elements of the atmosphere change. Their pressures change and the relative quantities, I presume, change.

Many of the techniques, the sciences, the theories that are required are merely extensions.

Mr. KEATING. For instance, specifically, we have craft that go through the atmosphere, what we call air-breathing equipment. Now, that is not suitable for use in outer space, is it?

General PUTT. That is correct, so far as propulsion is concerned. When we get out to the point where there is insufficient oxygen in the air to support combustion, then we must carry our oxygen along in order to create propulsion or a driving thrust.

That is what we do with the rocket. We carry the oxygen with us so that it can operate outside of the earth's atmosphere.

Mr. KEATING. You drew the parallel of the air being somewhat like the sea where there was a greater density or less density at different depths. As it has impressed me, and I certainly have an open mind on these problems, it is more a distinction between land and sea when you get into true outer space as against the atmosphere, in that the two are entirely different, not in degree, but in kind.

Now, you do not share that?

General PUTT. No, I believe not. I would agree that there is quite a difference between the land and space, but in my belief space in its broader sense starts just as soon as you leave the surface of the earth.

Surely there are different properties, different values of pressure, temperature, density, but it is a continuous variation of these properties and it is not just something that has suddenly become entirely different.

Ever since we have started to fly we have attempted to go higher, faster, and farther and we have gone through tremendous changes of pressure when you just go from the surface of the earth to 100,000 feet.

For instance, I think it is 99 percent of the earth's atmosphere which is below 20 miles altitude. When operating now at around 100,000 feet, many of the changes will be of a lesser degree from there on out than some of the things we have already gone through.

There will be different elements, different problems, but we think much of the theory, many of the techniques and propulsion systems, that have applied to aeronautics, guidance, probes, extend right on up.

The CHAIRMAN. Mr. Keating, might I interrupt at this moment. I have to go to the floor. Mr. Brooks will take over.

Dr. Dryden, you are available at any time, are you not, sir?

Dr. DRYDEN. Yes.

The CHAIRMAN. There is a bill up this afternoon. I think the committee would be under extreme pressure if they were to meet and could not explore as fully as they want to, so you will be available at any time they want you? You are here in Washington?

Dr. DRYDEN. Yes.

The CHAIRMAN. I hope you gentlemen will be able to conclude with the general.

But you understand, Doctor, we have no meeting this afternoon. You are available at any time at the convenience of the committee?

Dr. DRYDEN. Yes.

The CHAIRMAN. Thank you.

Mr. Brooks, will you take over?

Mr. KEATING. General Putt, there is much of the equipment and techniques which would be applicable to aeronautics which would not be applicable to astronautics also?

General PUTT. That is correct. There are new problems that will arise that we have not had to date. They become additive to the problems we have had in aeronautics.

Mr. KEATING. Do you not feel that there should be a complete redefinition of the missions of the three services, if for no other reason than because none of them now covers—and if you take issue with this, of course, you are free to do so—because none of them now covers outer space which could conceivably be tomorrow's principal battlefield.

General PUTT. Certainly, technology has provided weapons that cross present lines of service reponsibilities.

Likewise, it is questionable as to whether future wars will follow the classical lines of land, sea, and air.

If seems as though it would be probable that any given operation is a combination of all three types of warfare. I believe I would agree that we certainly must examine this and make sure that we are not following too much tradition and being unrealistic as to what kind of wars are going to be fought in the future with what kind of weapons. We might find ourselves not properly organized to carry out effective campaigns.

Mr. KEATING. In other words, our present missions are stated primarily in terms of land, sea, and air?

General PUTT. That is correct.

Mr. KEATING. And this concept, including the concept of outer space, calls for at least a reexamination of the definition of the missions of our three services?

General PUTT. I think that is correct.

Mr. KEATING. I was very much pleased to see the statement on page 3 of your fine presentation:

> We in the military fervently hope that all nations join together in whatever measures need be taken to insure that space is never used for any but peaceful purposes.

Resolutions we have introduced declare such to be the sense of Congress.

Now, do you think that the adoption by Congress of that principle—although the sense of congressional resolutions has no legal effect, it is often said—would have far-reaching effects among other nations in promulgating that idea among the peoples of the world?

General PUTT. I would certainly think so.

It seems to me that the United States, by whatever means is considered appropriate, should declare its intention and its feelings that space should be used for peaceful purposes.

Mr. KEATING. Thank you.

That is all, Mr. Chairman.

Mr. BROOKS (presiding). Mr. Ford?

Mr. FORD. General Putt, I have been impressed with your comments concerning the Department of Defense and primarily the Air Force working arrangements with the NACA and your tribute to the various programs that NACA has made possible.

Could you explain for the benefit of the committee what your past relationships have been with NACA? How does the Department of the Air Force, your office, work with NACA today?

General PUTT. First, there is a clear understanding between the individual services and the Department of Defense as to just the responsibilities and functions of the NACA as they pertain to research in aeronautics.

We look to the NACA for much of our basic research and fundamental knowledge that is applied by industry and the services in the actual development and design and production of weapons systems

Now, because of the facilities, the competence of the NACA in addition to their national responsibility for fundamental research in aeronautics, they on our request also undertake programs to assist the military and industry in the actual development of military weapons systems.

Mr. FORD Does the Air Force initiate these programs, or does NACA initiate such programs?

General PUTT. It works in this manner. The Air Force, for instance, would initiate a program for a new bombardment aircraft, let us say. We have to work out a considerable testing program, which includes the wind-tunnel testing of models.

We get together with the NACA and jointly work out testing programs where their facilities are most adaptable and their capabilities will get the job done the quickest and the best.

Industry itself has some of its own wind tunnels and there are other nonprofit organizations that operate wind tunnels and the Air Force and the Navy have some of their own.

These are all considered in toto. It is the question of the carpenter using the right tool for the right purpose.

Mr. FORD. As far as the military is concerned, somebody else comes up with a weapon requirement. From that point on, either through industry or through NACA, the research and development is carried on?

General PUTT. That is correct.

There is a standardized procedure whereby we make requests on NACA to carry out programs. These are all coordinated with NACA before a piece of paperwork goes through, to make sure, 1, that they accept it; 2, that it fits into the schedule, and 3, that the priorities are all in order.

The large part of the good relationship that exists between the Department of Defense, the services, and the NACA, is their system of subcommittees and panels on which there are members of industry and science and military representatives from the appropriate research and development activities and fields of operation.

Mr. FORD. I raise this question because, as you undoubtedly know, one of the proposals in the legislation is that there should be this committee of 17, including 8 from the various departments in the Government and 9 from without. One of the representatives from the Government would be somebody from the Department of Defense.

Now, do you feel that 1 out of 17 on such a board is adequate to represent the views of the Department of Defense?

General PUTT. I personally would prefer to see something different than the way it is stated. I do not believe the legislation precludes more than the one from the Department of Defense. It is my own feeling, and I believe it is that of the Air Force, that we would prefer to see the legislation specifically spell out 1 from the Department of Defense and 1 from each of the services.

Mr. FORD. That was the point I was getting to. Should we make it as it is here, which is just one mandatorily with the possibility of more, or should this committee recommend to the House that we should specify, such as you have suggested as 1 alternative, somebody from the Department of Defense and possibly 1 from each of the 3 services?

General PUTT. I think this is something that your committee should give real thought to, because I visualize a new agency being just as important to the military as has been NACA in the field of aeronautics.

It would seem to me that this has been so successful and the relationship is so important to our national progress in aeronautics and space, that we should try to retain the same general pattern.

It seems to me that the best interest of the Nation and the services and the space agency would be best served if we could specifically have Department of Defense, Navy, and Air representation.

Mr. FORD. Would you think it wise to pin down that the representation from each of the 3 services should be military or leave it flexible enough so that it would be a person from each of the 3 services, either military or civilian?

General PUTT. I believe I would make it military. I would hate to see a specific individual by office named. I can see some difficulties there, but I believe that I would prefer to see a military man because there will be civilian, scientific and technical people on the membership of the board from other organizations and activities and one, it seems to me, wants to get a sprinkling of military thinking because there will be plenty of scientific and technical competence within the board from other sources.

Mr. FORD. I am not personally familiar with the details of the relationship of AEC with the Department of Defense and the respective services, but it is my impression that there is one active military person who is attached to or serves with AEC, but he is bolstered up, so to speak, by a military liaison committee.

Would such an arrangement as that be adequate or would you prefer the suggestion that you made a few minutes ago?

General PUTT. I suppose another arrangement could be worked out, something along the line of the AEC. I do not know what Dr. Dryden thinks about this, but I think the relationship and the procedures for liaison and mutual support have been so successful in the past that it seems to me that rather than upset a system that is working so successfully now, that we ought to maintain that same pattern unless there is something I do not see that is new as we broaden NACA's activities into space.

I think we will get on with the job faster and with greater understanding if we can maintain the same pattern.

Mr. FORD. Would you like to comment, Dr. Dryden?

Dr. DRYDEN. Yes, I would like to mention a reason for the bill being written the way it is.

If you start spelling out the Government membership, I do not believe that you will be able to stop with the military. I think the AEC should certainly be represented, the Science Foundation involved.

I think once you start spelling them out you will have to spell them all out.

In the past we have had the situation where the particular membership was spelled out and then the legislation is changed and there is some other agency, then you have to come back and change the legislation to match.

So I believe the purpose of this is not to keep out any representation from any particular department or service, but to leave it flexible so that you would not have to amend this as soon as you gentlemen get through with the military reorganization bill, for example.

This possibility exists, of course, when you spell out particular individuals. The statutes change and you have to amend the legislation.

Mr. FORD. Does NACA now do work for all three services?

Dr. DRYDEN. Yes.

Mr. FORD. More or less along the same pattern with each?

Dr. DRYDEN. Yes. Up until the present time the Army has not been represented. There is a bill which has passed the House and is now on the floor of the Senate, which is quite obsolete now, of course, if you consider this legislation, but that did provide for 2 members from the Army just as they are 2 from the Navy and 2 from the Air Force on the present committee.

Mr. BROOKS. Mr. Ford, Mr. Feldman wants to ask a question right there.

Mr. FELDMAN. Dr. Dryden. Don't you think that the AEC has operated fairly well with the military and that that is written into the law?

Dr. DRYDEN. I did not make a comment on this suggestion. I think this is a way of bringing men in uniform into the picture. Presently, they are brought into membership on the Board, the Advisory Committee. They have liaison officers stationed at major laboratories. The Navy does it by traveling liaison.

Mr. FELDMAN. Don't you think it should be spelled out in the law?

Dr. DRYDEN. I think the military part of the agreement should be available and represented in some form. I think I would defer to you as to how it is finally left.

Mr. FELDMAN. Should this not be spelled out because the person in charge of, say, the new NASA, might be changed and have a different philosophy? He might, at his whim, decide that he does not need a military man.

Dr. DRYDEN. At present it is left in the hands of the President to nominate the Government agencies. That is the way the language is written now.

Mr. FELDMAN. You would have no objection to its being spelled out?

Dr. DRYDEN. I personally have no objection.

Mr. FELDMAN. Thank you.

Mr. BROOKS. Mr. Ford.

Mr. FORD. One general question, General Putt. From time to time there are some intimations that we have inadequate testing facilities such as those at Cape Canaveral for the successful prosecution of our present and contemplated programs Would you care to comment on that situation?

General PUTT. Yes. I guess we are in no different situation now than we have been in the past, at least in my experience. Testing facilities are always a difficult problem One must foresee considerably in advance of the actual need that facilities of some nature are going to be required.

In many cases the facilities themselves are quite a research and development problem, just to design the tools and then get them built.

So that in general our experience has been that from the standpoint of capabilities and timeliness we are always a little behind the race, sometimes a lot behind, in our own programs.

Now, the machinery of Government makes it difficult to get facilities timely and of proper scope and capacity. Most of our facilities are built with public-works funds. This is not an easy process, to go through all the process of authorization and appropriation. Lead time is great; the administrative lead time is great

Mr. FORD. The Bureau of the Budget?

General PUTT. The Bureau of the Budget, and all the agencies, of course, that must approve facilities and expenditure of funds.

It is really difficult to sell facilities when the need is not almost upon us. Then it is too late.

Mr. FORD. Would you say that the present construction program at Cape Canaveral or any other place is adequate for the missile and satellite programs which we are currently executing and working on?

General PUTT. I think at present, because of the priority and emphasis on ballistic missiles, that there is no lack of funds for the facilities at Cape Canaveral We wish that we had funds available sooner in the past so that it would not be such a nip-and-tuck operation now to get the facilities ready at the time the hardware is going to be there to test.

We are still running close on that.

But to the extent of our capabilities of actually designing and constructing the facilities that are needed there, there is no shortage of funds in that area.

Mr. FORD. Thank you very much.

Mr. BROOKS. Before counsel ask questions, may I say this.

Dr. Dryden was going to testify today, but the chairman has already announced that we will have to hear him later. His statement is available here.

I understand the press has it. If it is all right with you, Doctor, since some of the statements probably have gotten away from the committee room already, is it all right to assume that you have made that statement for the press and let the press carry that statement?

Dr. DRYDEN. Yes, or you can read it into your record.

Mr. BROOKS. I think tomorrow that will be up to the chairman. He will probably wish you to go over it so that we can ask you questions about it.

Dr. DRYDEN. Certainly. If you wish to regularize it, you can introduce it in the record and defer questions until later.

Mr. BROOKS. If there is no objection, it will be made a part of the record and if there is no objection by you, we will let the press print it.

Dr. DRYDEN. I am only trying to get out of writing a new statement.

(The statement referred to is on p. 401.)

Mr. FELDMAN. General Putt, is it not true that the recent Soviet satellites, as well as ours, could be regarded as part of the International Geophysical Year program and, therefore, do not set any precedent for future rulings on passage over various countries?

General PUTT. Yes, I think they could be thought of in that regard. Because the legal aspects of the problem have been so difficult, maybe this is a good approach.

Mr. FELDMAN. General, you mentioned that the Air Force has a project similar to the Army's, to get a man into space, other than the X–15. Can you tell us about it?

General PUTT The status of the project is the same as that mentioned by Dr. von Braun, but still not approved. In technical detail it goes a little bit further than the Army project.

Our goal here would at least be to have the vehicle make a couple of circles before returning to earth.

Mr. FELDMAN. How far along is the program?

General PUTT. Not much further than the study stage except there is some hardware that has been developed and being used in other programs that would be applicable to this at the time that such a program were approved.

Mr. FELDMAN. I think Dr. von Braun indicated that we might be able, or he might be able, to accomplish such a mission within a year. Do you think you could do likewise?

General PUTT I think we could do a similar program in a year. I do not believe we could do the program we have in mind in a year, which is a little more difficult. And I think it would reward us with more useful data than Dr. von Braun's program.

Mr. FELDMAN. Do you have any idea how long the project would take?

General PUTT. It would be of the order of a couple of years.

Mr. FELDMAN How does the United States stand in comparison with Russia in relation to the conquest of space?

General PUTT. This kind of question always becomes a little difficult because where one stands is the summation of where we stand in a lot of smaller areas.

In the conquest of space, of course, one must be concerned with propulsion systems, with guidance systems, with structures, and things of that nature.

So in answering the question, are we ahead or are the Russians ahead, one must attempt to summarize and average out all of the elements that are required to get into space.

Maybe I could best give you a feel for this It is my view that for the next 2 or 3 years, if the Russians chose to do so—and this is an important distinction, if they chose—I think that they could probably outperform us in some of the things that can be done in further exploration of space.

I feel reasonably sure that in the broad basic research leading toward space that on balance we are probably ahead. In the area of rocketry it would seem to me they may have a little edge on us there.

Mr. FELDMAN. When can we hope to go ahead of the Russians if we, to use your word, expend the thought, money, and effort required?

General PUTT. I think it is certainly going to take a lot of effort. It would seem to me to be at least 2 or 3 years before we might be even with them.

Of course, they are not going to be standing still, either. I think we have a pretty tough row ahead of us for the next 5 years and possibly a longer period of time.

Mr. FELDMAN. Turning to missiles, what future advancements are in store for our future ballistic-missiles programs?

General PUTT. In general, I think that advancements in high-energy fuels, both liquid and solid, are going to give us greater ranges, greater payloads, greater yields for any given weight of rocket

Certainly, going to the solid fuels is going to simplify our ballistic missiles. They are going to materially improve the reaction time.

The logistics problems with solid propellents are much simpler than liquid propellents. I think you will find them getting cheaper, and smaller. Their guidance should be improved.

There is quite a broad base that we have developed that is going to lead to considerable improvements in our ballistic missiles.

Mr. FELDMAN. What are the prospects for ascendancy in the race between ballistic missiles, the antimissile missiles, and the countermeasure antimissiles?

General PUTT. Although the problem has become more and more difficult as weapons become more and more sophisticated and complicated, I do not see any significance between the measure and the countermeasure race, so to speak, with missiles than we have had with other military weapons and aircraft.

At one period of time the offense will be in the ascendancy and at other times the defense seems to be in the ascendancy.

I predict we will find in space weapons the same sort of race between the measure and the countermeasure.

Mr. FELDMAN. How successful would photography and other information be, that is, information acquired, in a vehicle carrying out a military reconnaissance mission?

I am referring now to the techniques.

General PUTT. I think they will be very successful. Enough work has been done in this area to indicate very great promise that we will have photography and television that will give us real usable reconnaissance data.

Mr. FELDMAN. Could satellites be used for active rather than passive defensive purposes?

General PUTT. I think this would be feasible. There are a lot of questions as to whether it would be practical for the way one would want to carry on a defensive campaign. There may be easier, better, and cheaper ways of doing it, but I certainly would not discount the possibilities of using satellite vehicles of some sort or nature as offensive, active weapons.

Mr. FELDMAN. Could the satellites carry their own defensive measures?

General PUTT. This is conceivable in some forms. Again it might be a question of feasibility and still be quite impractical, but I certainly would not rule the possibility out.

Mr. FELDMAN. What would be the military role of the manned orbiting vehicle?

General PUTT. At the present time it is difficult to foresee that mechanical gadgets in the sky with computers, but lacking human intelligence and judgment, will be able to perform all of the missions of reconnaissance and bombing of targets for a considerable period of time.

There is always going to be unknown targets. There may be fleeting targets.

For a period of time we may not know accurately enough the actual location of targets with relation to launching points to get ballistic missiles on them, so that it seems to us that the man is still required whether we are flying in the sensible atmosphere or outside of the sensible atmosphere into space.

Mr. McDONOUGH. General, you used the words "sensible atmosphere" several times this morning. I would like to have you define that. I do not get the point.

General PUTT. This is a term that is used in the scientific community, I guess. It generally, I think, means that level at which there is sufficient atmosphere to support winged flight.

Dr. DRYDEN. Or where the forces due to the atmosphere are an appreciable element to propulsion.

Mr. McDONOUGH. It would be inner space, then?

Dr. DRYDEN. It would still be closer to inner space. Part of the atmosphere where Sputnik 2 just burned up is certainly sensible atmosphere because it got red hot.

Mr. McDONOUGH. I do not understand the word sensible.

Dr. DRYDEN. You can detect it.

Mr. McDONOUGH. It is detectable by the senses of man?

Dr. DRYDEN. That is right.

Mr. BROOKS. May I suggest this question there? I thought from the use of the words "sensible atmosphere" that you had in mind that in space the variable influence affecting flight would be simplified by not having air currents and things of that sort.

Would you want to express yourself on that?

General PUTT. Well, we certainly get away from some problems out in space that result from having an atmosphere. In getting back to earth from outer space one must make this reentry into the atmosphere and, of course, the forces would become quite great.

So in going into space we acquire some new problems and we get rid of them too, as long as you stay there.

When you come back in you have all of them.

Mr. McDONOUGH. It is beyond the drag area?

General PUTT. Yes.

Mr. McDONOUGH. Within the drag area is sensible atmosphere?

General PUTT. That is right.

Mr. FULTON. It includes then the thermosphere, but it does not include exosphere?

Dr. DRYDEN. That is roughly correct.

Mr. FULTON. And it does not go out beyond a thousand miles?

General PUTT. No.

Mr. FULTON. Where the atmosphere ends. Is that right?

General PUTT. Yes.

Mr. FELDMAN. What might be the future relationship between space-vehicle missiles and aircraft, missile-launching submarines, and other systems?

General PUTT. Thinking in terms of warfare, it certainly would be dangerous to base your operations on a single strategy. It is equally as dangerous to base your operations on a single weapon so that it appears to us to be very important that we have families of weapons so that the enemy does not know which one you are going to use. It complicates his problem in developing countermeasures for a multiplicity of different weapons than if you just had one.

So it would be extremely dangerous to concentrate on one, and, therefore, I think to the extent that the country is able to afford it, there should be a variety of weapons to carry out military operations.

Mr. FELDMAN. Addressing ourselves to the NASA legislation, what in your opinion should the scope of the NASA be in the space field?

General PUTT. Here, I believe that, if we can use the analogy or the example, it seems to me that NASA should perform almost the same role across the board, aeronautics, space, and its relationships, with all the agencies of the Government in essentially the same manner and the same method that has been practiced in the past within the area of aeronautics.

In other words, they would direct the civilian research programs. They would aid the military in their programs and the military certainly would want to look to the NASA for the basic research and knowledge, fundamental knowledge, that would be usable by industry and the services for the development of any military weapons that might be developed for utilization in space.

So I view their role and their relationships as just remaining practically the same except extending in scope from conventional aeronautics into space.

Mr. FELDMAN. The emphasis on the scope, at the present time, is in an advisory capacity. Is that not true?

General PUTT. No, this I do not believe is true. While that is in the name, National Advisory Committee for Aeronautics, they actually carry out research and development in aeronautics, aeronautical science.

It is true that they do render a lot of advice and helpful advice, to the military services, particularly on problems in the development of military weapons.

So that they do act in an advisory capacity, but in addition they have operating responsibilities.

Mr. FELDMAN. The emphasis, though, is on advice rather than on operations. Is that right?

General PUTT. I would think it was the other way around. If one considers the scope of their facilities and their operations and what not, I think the major emphasis is on actual operations.

Mr. FELDMAN. Is it your testimony that they have a great deal of know-how in the development of scientific techniques of that sort?

General PUTT. That is correct.

Mr. FELDMAN. The proposed NASA legislation changes the relationship of the Board and the Director and the method of selecting the members of the Board, the DOD membership, from that of the NACA.

What are your views on this portion of the proposed legislation?

General PUTT. I certainly would like to see the new agency function as it has in the past. I believe in the new legislation for the agency the Board itself becomes advisory to the Director.

I believe the best description of the relationship of the Board to the Director at present is that they really do act in an executive capacity so far as programing, planning, and budgeting are concerned.

They act like a sort of board of directors for the Director and the NACA.

I have not conferred with Dr. Dryden, but it seems to me this has worked so extremely well that to upset that kind of operation would be disappointing, at least to me.

I wonder whether a board that is advisory only, and meets only once every 4 months, as I believe the legislation calls for, whether you would get the intense interest, the caliber of people and whether they would be of the assistance to the Director that the present Board is.

Mr. FELDMAN. You just said you would like to see them operate as they have in the past. The only other function that we would add to it is this jurisdiction in outer space.

Then do you think it would take legislation, or it should take legislation to accomplish that purpose, or could it be done by Executive order?

General PUTT. I do not believe I am enough of a legal mind to comment on that.

It would seem to me that there are advantages in having it a subject of legislation to expand the scope of activities.

Mr. BROOKS. Of course, that does change the fundamental purpose of the agency by asking it to take over space.

General PUTT. That is right.

Mr. BROOKS. I want to ask you this.

What, in your mind, is going to be the essential difference between the NACA, that is, the National Advisory Committee for Aeronautics, and NASA, the agency referred to in the bill? Would they not be advisory? Would they not both be advisory?

General PUTT. It would seem to me that NASA would still function in an advisory capacity in the same way that they have in the past.

Mr. BROOKS. It is proposed to be a new agency.

General PUTT. It does seem to me that it has somewhat of a greater responsibility for the national program in space than it has had for a national program in aeronautics.

Dr. DRYDEN. Mr. Chairman, the bill, of course, provides that NASA shall at least direct the firing of satellites to obtain information in outer space, that they should be responsible for actual developments that are needed in the advance of the civil-space question and it will require a considerable change in the NACA, there will be a wholly new operation which will largely have to be operated by contract-type operation.

Mr. BROOKS. How would you differentiate between the two? Is there not a good deal of overlapping there?

For instance, would not both be advisory and would not both be also an operating agency for experimentation?

Dr. DRYDEN. The advisory feature has been very limited. That name has been obsolete for something like 30 years.

Mr. BROOKS. You mean NACA?

Dr. DRYDEN. The NACA name. The term advisory is obsolete. In the early days they did advise the Government on setting up the Civil Air Commerce Act.

Mr. BROOKS. That is true, and they have an extensive program for development there, but they still are advisory, are they not?

Dr. DRYDEN. The present advice is technical advice, if I can make a distinction between a group that advises on technical matters and one which gives overall advice on aeronautical matters in general.

Mr. BROOKS. NASA would be theoretical?

Dr. DRYDEN. NASA would do the same thing. It also would be engaged in actual operations. It has not yet been determined which specific projects now handled by the Advanced Research Projects Agency will be handled by the new agency.

For example, the type of operation embodied in the lunar problems would become the responsibility of the new agency rather than the Department of Defense.

That is a large operation as compared with our present laboratory operations.

Mr. BROOKS. The Advance Research Projects Agency would be under the Defense Department, but it will cover the same field?

Dr. DRYDEN. No. The President, as you know, has stated that these projects are to be examined to decide which will be transferred to the new agency. The approval for conducting the civil program in the Advanced Research Projects Agency is a temporary thing, subject to reexamination.

Mr. BROOKS. Does not the law make it other than that?

Dr. DRYDEN. The law says they have the responsibility until February of next year. This is the present legislation.

Mr. FULTON. On that point, Mr. Brooks, I have a question.

Would legislation to establish this National Space Agency, that has in it a provision limiting the Department of Defense to only those projects that have a well-defined military application, injure or weaken the Department of Defense in your opinion?

I would like to ask both the General and yourself, Doctor, that question, for the record.

Dr. DRYDEN. I think you realize I did not write this particular language. The determination of the policies in this matter lie with the President and the Congress.

Mr. FULTON. Would such a limitation weaken the Department of Defense or ARPA?

Dr. DRYDEN. It depends on its interpretation and this is not completely clear, I think, at the moment.

Mr. FULTON. You would disagree with Dr. York, who yesterday felt such a provision would weaken the Department of Defense and ARPA?

Dr. DRYDEN. It would weaken them in the sense that they are not doing the whole space job, civil and military. That weakens them by taking part of the work away, if you want to call it weakening the Department of Defense.

I do not think it will weaken the defense of our country to have this transfer made.

Mr. FULTON. So the overall program would be strengthened by such a provision?

Dr. DRYDEN. The overall program would be strengthened by this.

Mr. FULTON. I would like the General to answer that, too, if he will.

General PUTT. As Dr. Dryden said, the present language is subject to interpretation and so far as the responsibilities for the research that

the military can carry out, we would like to see that expressed as now contained in the President's Executive Order 51021, which does permit the military services to engage in basic research that is closely allied to military problems.

Mr. FULTON. So that would be a better statement, really, than a well-defined military reason?

General PUTT. We think so. The well-defined military reason is subject to some interpretation.

We like the language of 10521.

Mr. FULTON. At that point, would you put the language in the record with the chairman's permission?

General PUTT. Yes.

Mr. FORD. I would have no objection to the language being included in the record of section 10521 so that we may have it for reference.

Mr. FULTON. And also the language of the administration bill in the record, for comparison at this point.

Mr. BROOKS. You mean insert the entire bill?

Mr. FULTON. No; just this provision.

Mr. BROOKS. If there is no objection, it will be so ordered.

(The material referred to follows:)

The following language is extracted from section 4, Executive Order 10521, administration of scientific research by agencies of the Federal Government, dated November 17, 1954: "the conduct and support by other Federal agencies of basic research in areas which are closely related to their missions is recognized as important and desirable, especially in response to current national needs, and shall continue " The language noted above is preferred to the following language of H. R. 11881, page 2, lines 7 through 10.

"The Congress further declares that such activities should be directed by a civilian agency exercising control over aeronautical and space research sponsored by the United States, except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations, in which case the agency may act in cooperation with, or on behalf of, the Department of Defense."

Mr. BROOKS. Now, Mr. Metcalf.

Mr. METCALF. I was interested in Mr. Feldman's questions directed to General Putt. I would like to ask Dr. Dryden this:

In view of the statements that have been made, the General says he would like to see the new agency function as it has in the past.

In your outline the functions of the new agency would largely be an expansion of some of the duties and performances you have made in the past.

Again, what is the need here for legislation?

Dr. DRYDEN. The need for legislation is a very simple fact that there is not in any one agency all of the skills involved in the space program NACA, for example, does not have any laboratory devoted to research and communications, guidance control. Legislation will be necessary to give us the broad contracting authority necessary to operate in that fashion in this area which is needed in the space program.

The second point I think the lawyers can perhaps argue, I don't know. I feel much happier with a clear statement that we are empowered to operate space vehicles, rather than rely on some interpretation.

Aeronautical research never has been fruitful in the absence of close contact with flying. The NACA, as you know, operates aircraft, does flight research on aircraft.

General Putt will give us an airplane costing $5 million, turn it over to us for scientific experiments. We feel in the space field research will be fruitless unless it is coupled with actual space experiments.

It seemed to us that this authority is specifically needed.

Mr. BROOKS. Do you think the Comptroller might question your expenditures?

Dr. DRYDEN. Exactly.

Mr. METCALF. That may well be true, that for certain technical reasons it is necessary to have authorizing legislation, but as I gathered from the testimony here today, it is only contemplated that this new agency, NASA, is going to function about as the former NACA has functioned with some broadened authority, but function along the lines—and you desire it to function along the same lines—that you have functioned in the past?

Dr. DRYDEN. Yes.

May I say I have much sympathy with this point of view. I started out a year ago with the idea that the public should be educated to the fact that aeronautics was an expanding concept.

As General Putt so well expressed in his testimony, we are spreading further, the same elementary sciences are needed, no change will be necessary in need.

This proved to be a losing game. Astronautics is quite different from aeronautics in the public mind. It is true in some areas that have been referred to, Ion motors which have no application to the atmosphere, there are some areas in which we have to move to get in to outer space that are not immediately in our knowledge.

Mr. METCALF. I think that is the whole crux of the matter before this committee, the various research problems with which you are going to be concerned, if you are the Director of the new agency.

The committee wants to know where the space astronautics thing will be in the Government. That is our basic mission.

That is why I am making this inquiry because I do not know where it should be.

Mr. DRYDEN. Space is too big to be in one agency. It has a civil as well as military aspect.

I am sure you are familiar with the argument for not putting the civil side of things wholly within the military. It immediately would make almost impossible the discussion of peaceful uses of space and international cooperation.

I do not believe it is right to write the military out of space. I believe it would be an equally serious error to put all of space in a purely civilian agency.

Mr. METCALF. The thing that troubles me is that I agree with you and I am a little bit unhappy, to use your phrase, about putting this thing in a glorified and just a little bit amplified NACA. That seems to be the direction in which this legislation is going.

Dr. DRYDEN. I think the legislation going that way sets up a completely new agency. Instead of setting up an office in some other building and putting out its employment opportunities for people who have to come from our place and from the military, instead of coming to Congress to reproduce the facilities that we already have which enabled the study of these reentry problems, this proposes a new agency

which uses the resources of trained manpower, trained teams, facilities that are available.

It is not the NACA. This bill is not the NACA as it now exists if you read it carefully.

General Putt said he favored the NACA as it now exists.

Mr. McDONOUGH. Are not the two problems so correlated that you could call it a national aeroastronautics agency?

Dr. DRYDEN. Yes.

Mr. McDONOUGH. That would encompass both sensible atmosphere and outer space.

Dr. DRYDEN. There have been bills introduced which propose a different name, NACAA, National Advisory Committee for Aeronautics and Astronautics.

This is a matter of name. I think advisory is not the proper adjective in the name.

Mr. McDONOUGH. The thing you want to do is be back here. The idea of building up bureaucracy is too much. We do not want to have 2 office buildings where we can operate in 1 and do the same thing.

Mr. FULTON. Would it not be advisable, though, to have a civilian agency which has the direct primary responsibility for an overall civilian-military research, development, and exploratory policy, as well as the overall primary responsibility for implementing those various programs.

That is, combining all the functions under one policy making civilian agency, with military given its adequate place.

Dr. DRYDEN. Of course, you are now speaking of a very controversial matter, whether to take the role of research from the military departments and set it up outside in a civilian agency.

I personally have not been in favor of that solution because I think it divorces the science too much from the military.

Mr. FULTON. My intention is not to take from the military the programs that are related to military functions as well as basic research which might be allied. We cannot tell now, but they might feel it is within their power.

I feel we should have outer space not just explored, but conquered by the military.

Dr. DRYDEN. I think you are talking about what I suppose the bill is intended to accomplish.

Mr. BROOKS. Gentlemen, there is a quorum call. We are not going to be able to finish. We have finished with General Putt, but we have gotten into an area we will not be able to finish today. What is the pleasure of the committee?

If there is no objection it would seem to me that the thing to do is to adjourn until tomorrow morning at 10 o'clock.

We thank you very much, General Putt; we have finished with you. We would like to have Dr. Dryden at a later date.

General PUTT. Thank you very much, Mr. Chairman.

(Thereupon, at 12:40 p. m., the committee was recessed, to reconvene at 10 a. m., Thursday, April 17, 1958.)

ASTRONAUTICS AND SPACE EXPLORATION

THURSDAY, APRIL 17, 1958

House of Representatives,
Select Committee on Astronautics
and Space Exploration,
Washington, D. C.

The committee met, at 10 a. m., pursuant to recess, in the Caucus Room, Old House Office Building, Hon. John W. McCormack (chairman) presiding.

Present: Representatives McCormack, Brooks, O'Brien, Metcalf, Natcher, Sisk, McDonough, Fulton, Keating, and Ford.

Present also: George J. Feldman, Director and Chief Counsel.

The Chairman. The committee will be in order.

We are very happy to have as the first witness today and are glad to welcome Maj. Gen. John B. Medaris, whose outstanding work in connection with the international interest of our country on the part of the Missile Command is well known.

We are glad to have you here with us, General, and we shall be glad to hear your testimony.

STATEMENT OF MAJ. GEN. J. B. MEDARIS,[5] COMMANDING GENERAL, UNITED STATES ARMY ORDNANCE MISSILE COMMAND

General Medaris. Thank you, Mr. Chairman.

Mr. Chairman and gentlemen of the committee, with your permission I should like to start with a short prepared statement, after which I shall be wholly responsive to the questions of the committee

First of all, I want to thank you for this opportunity to appear before you. I am here as the commanding general of the United States Army Ordnance Missile Command

After giving you a brief summary of the command's activities, I will be fully responsive to your questions.

The United States Army Ordnance Missile Command was recently established to assure full coordination and utilization of the facilities and technical resources of the Army Rocket and Guided Missile Agency, the Army Ballistic Missile Agency, White Sands Proving Ground, and Jet Propulsion Laboratory.

---

[5] Maj Gen. J. B. Medaris is commander of the Army Ballistic Missile Agency. His responsibilities include the development and establishment of the Redstone and intermediate-range ballistic missiles as weapons systems for the United States Army.

Born in Milford, Ohio, on May 12, 1902, he enlisted in the United States Marine Corps in 1918 and served in France during World War I.

In 1921, he was commissioned as a lieutenant of infantry and served with the 29th and 33d Infantry Regiments until detailed in the Ordnance Corps in 1926

In October 1927, he resigned from the Army and for 10 years engaged in merchandising and management advisory activities in the business world

In July 1939 he returned to active service and served successively until 1942 as executive officer, Cincinnati Ordnance District; assistant, district control office, Office Chief of Ordnance, executive, Contract Distribution Section, Office of the Under Secretary of War (with Secretary Patterson).

In spring of 1942, he took to the field and was successively battalion commander, ordnance officer, II Corps—campaign in Tunisia, invasion of Sicily and Sicilian campaign

Later he transferred to England as ordnance officer for the First Army and planned and executed ordnance portion of First Army's invasion of Normandy, remaining as ordnance officer for that Army's campaign in Europe.

After V-E Day, he served in turn as ordnance officer, Fifth Service Command, ordnance officer, Army Ground Forces; Chief, United States Army Mission to Argentina from 1949 to 1952.

Returning in June 1952, he became executive and Assistant Chief, Ammunition Branch, Industrial Division, and in May 1953 he became Chief of the Ammunition Branch, which position he held until his assignment as Assistant Chief of Ordnance and Chief of the Industrial Division of the Office, Chief of Ordnance, in November 1953

He was promoted to the rank of major general on September 15, 1955.

In Number 1955, he was designated as commanding general of the Army Ballistic Missile Agency

Among the decorations he has been awarded are the Distinguished Service Medal (for the European invasion and the campaign following), the Legion of Merit, Bronze Star Medal, Soldier's Medal, and the French Legion of Honor.

At present, the Army Rocket and Guided Missile Agency is responsible for the development and industrial production of surface-to-surface antiaircraft missile systems and comparatively short-range surface-to-surface missile systems.

This agency is also engaged in the development of the Nike-Zeus antimissile system.

The Army Ballistic Missile Agency is developing the longer range ballistic missile systems, including Redstone, Jupiter, and now Pershing. This agency and the Jet Propulsion Laboratory are also engaged as a team in a satellite program which, as you know, has enjoyed considerable success to date, and I feel has demonstrated the Army's ability to efficiently coordinate and manage joint military-civilian scientific programs designed to yield scientific data.

Dr. von Braun is Director of Technical Development at ABMA. Beyond the field of ballistic missiles, our integrated development team led by Dr. von Braun is recognized as one of the leading scientific groups in the outer space field.

In fact, the first real emphasis on satellites in the United States came from Dr. von Braun, beginning about 10 years ago, and continuing through our successful launching of the first United States satellite and into the satellite program which we are now pursuing.

The term "integrated development" is our word for the development techniques which have been utilized in keeping Jupiter, our highest priority program, on schedule.

To accomplish this, the Redstone and Jupiter programs were placed under the same management so that the Jupiter program could take maximum advantage of the successes of its predecessor, the Redstone. Development of Redstone was carried forward, and production of the system for tactical employment is now underway and progressing very satisfactorily.

The establishment of the United States Army Ordnance Missile Command will permit ever broader application of these techniques.

In conclusion, I would like to make a few points clear. The United States Army Ordnance Missile Command is an experienced organization of thoroughly demonstrated capability. It is under the direction of the Army Chief of Ordnance.

Additionally, it has the unique advantage of immediate access to the Secretary of the Army and the Chief of Staff, when required.

It is further vested with command of all Army resources which relate to the execution of certain special priority missions. It serves national interests with the full measure of all Army resources, without any limitations as to whether either the end items produced or the knowledge gained are to be devoted to the sole use of any one military service.

We are doing this today by supplying the Air Force with Jupiter missiles and by giving this streamlined, integrated support to the Advanced Research Projects Agency in a national program of the utmost urgency.

We make maximum use of the expert advice and detailed scientific knowledge which are available from all sources in any field.

We frankly feel that we have built up an enviable record of accomplishment in meeting schedules as predicted and within our estimates of costs.

In light of this record, we certainly do not intend to commit ourselves to anything that we do not think we can accomplish.

This has been a very brief statement of our past record and present activity. I will now be pleased to respond to your questions.

The CHAIRMAN. Mr. Brooks.

Mr. BROOKS. General Medaris, I should like to ask you this. The United States Army Ordnance Missile Command is under the Ordnance Command?

General MEDARIS. That is correct. It is under the Army Chief of Ordnance.

Mr. BROOKS. What is it? Is it in the nature of an addition to the Ordnance Command?

General MEDARIS. It is a major field command of the Ordnance Corps.

Mr. BROOKS. How many commands do you have in Ordnance?

General MEDARIS. Major commands, there are four.

Mr. BROOKS. Are there any others related to missiles?

General MEDARIS. None.

Mr. BROOKS. Or satellites?

General MEDARIS. No, sir.

Mr. BROOKS. Or scientific exploration and experimentation?

General MEDARIS. Not in that area, sir.

Mr. BROOKS. So this is the only one which is under Ordnance that has any authority over missile development?

General MEDARIS. That is correct, sir.

Mr. BROOKS. Now, what is the specific difference between the Army Ordnance Missile Command and the technical development program?

General MEDARIS. I believe you refer, sir, to the technical development group under Dr. von Braun.

Mr. BROOKS. That is correct.

General MEDARIS. That is a part of the command, sir. It is a major segment of one of the elements of the command, the Army Ballistic Missile Agency.

Mr. BROOKS. Then Dr. von Braun is under your command?

General MEDARIS. That is correct, sir.

Mr. BROOKS. Does he have free rein in his experimental work? Is he subject to military discipline?

General MEDARIS. I don't think Dr. von Braun could be considered subject to any kind of discipline other than his own.

Mr. BROOKS. He is a very able man. I should think if he was put under military discipline he could take it like any of us.

General MEDARIS. I am sure he could and he is a very fine coworker; he is a fine man to work with. No one in the world, I believe, can really have complete freedom of action. We are all limited by such things as money and time and priority among the things that we must do and we all want to do more things than we have time for or money for.

Mr. BROOKS. Now, the Advanced Research Projects Agency—I believe that is the name of it—is a part of the Defense Department and you are a part of the Department of the Army

General MEDARIS. That is correct.

Mr. BROOKS. How will you work together?

General MEDARIS. My command works directly for the Advance Research Projects Agency in any project that its Director wants to assign to us.

Mr. BROOKS. Do you take orders in that respect from ARPA?

General MEDARIS. That is right.

Mr. BROOKS. Who has control of it, ARPA or the Army?

General MEDARIS. The ARPA controls their own projects. We stand in the same position as a contractor would to them, and we take their direction of the project. It is their project, their guidance, their directing it, and we are responsive to their desires.

Mr. BROOKS. Is ARPA now in charge of the satellite program, the Jupiter program, the Pershing program?

General MEDARIS. No, it is in charge of the satellite program. The Jupiter and Pershing programs, as military weapons systems, are not under ARPA.

Mr BROOKS. So your differentiation there is what is of a military nature and what is not?

General MEDARIS. The charter of the ARPA indicates that the Secretary of Defense will assign to that agency such advanced projects as he deems necessary within his concept of their mission. He has assigned to them the entire satellite and forward research field in those advanced areas

Mr. BROOKS. Now, do you have the facilities there in your command that you need for this work?

General MEDARIS. We have been very successful in managing to get most of the facilities that we need.

Mr. BROOKS. What do you lack, then? You say "most."

General MEDARIS I would not say as a conmander that I could ever say I was completely satisfied There is always something I would like to have.

On the other hand, we have what we require to do our job, sir.

Mr BROOKS. That is at the Redstone Arsenal?

General MEDARIS. Yes, sir, and at the Jet Propulsion Laboratory on the west coast.

Mr. BROOKS. Those two plants are under your command?

General MEDARIS. That is correct, sir.

Mr. BROOKS. What about Banana River? Do you have what you need there?

General MEDARIS. Yes, sir; we have what we need at the test range at Cape Canaveral.

Mr. BROOKS. You require material or additional facilities to continue this program?

General MEDARIS. There will always be additional facilities required because as the programs grow and the areas you go into grow, you have to have new types of technical resources to meet them.

There is no tremendous major facility requirement in connection with these programs as they stand now. There will always be small facilities requirements for any new program.

Mr BROOKS. But the major portion of your needs is satisfied?

General MEDARIS. That is correct.

Mr. BROOKS. By what you have already done?

General MEDARIS That is right, sir.

Mr BROOKS Now, are you satisfied with the progress of this program?

General MEDARIS. Well, again, I might say that anyone who is really interested in accomplishments is never quite satisfied. If I was entirely satisfied, I might become much too relaxed

We would like to go as far as we can.

Mr BROOKS Is there any way we can help you to go any faster?

General MEDARIS. I think at the present time, Mr. Congressman, that the resources that we have are being well utilized under the

direction of ARPA. We have constructive projects ahead of us and adequate to occupy our resources and our abilities for the immediate future.

Mr. BROOKS. Are we putting emphasis on the right part of your program? I mean legislatively. I will repeat that in a different way.

Are there any suggestions you can make as to how, legislatively, we could prepare a setup here in the Congress which would put more emphasis on the proper part of your program?

General MEDARIS. I think, Mr. Congressman, that the constitution of this committee is in itself a significant contribution and spells out this particular area as being of concern and importance and recognizes the need for attention to it.

Beyond that, I think the Congress has been extremely cooperative and helpful.

Mr. BROOKS. Well, a committee of this sort would be restricted to outer space, more or less, as I see it. What would be the restrictions, in your mind, if you were limited to the developments of outer space?

General MEDARIS. You mean if the resources of my command were so limited? This would be very unfortunate, because it is a balanced set of resources that is intended to carry forward the missile art and provide the Army with its requirements in terms of missile weapons.

At the same time, it has the capability and needs to continually move forward in the scientific field of exploration in order to advance its capability and we also are able and have capability of supporting scientific outer-space projects.

Mr. BROOKS. Would you refer to missiles as outer-space weapons?

General MEDARIS. The missile art is the basis for the outer-space use. It is the takeoff point.

The CHAIRMAN. It is hard to separate, too, is it not?

General MEDARIS Very hard to separate, Mr Congressman.

The CHAIRMAN. One leads to the other?

General MEDARIS. I believe so.

The CHAIRMAN. You cannot divide the situation.

General MEDARIS. I have a great deal of difficulty trying to do so in my own head because the cross contributions are continuous, all the time, every time something feeds back and forth from the scientific to the military.

Every new scientific development historically has given a concept to someone of how it might be used as part of a future weapons system.

So there is a great deal of interplay.

Mr. BROOKS. Certainly, the satellite program would be an outer-space program?

General MEDARIS. Yes, sir.

Mr. BROOKS. The platform program would be outer-space program?

General MEDARIS. Yes, sir.

Mr. BROOKS. Programs of that sort are well settled to be related to outer space?

General MEDARIS. Yes, sir.

Mr. BROOKS. The short-range missiles certainly are on the borderline?

General MEDARIS. Of course, when we consider space technology we are taking off from the point where a missile is a surface-to-surface weapon. That is, it is coming back to a point in earth as its immediate destination.

Its purpose is not to continue outside the atmosphere.

We consider any earth-based weapon, that is, to attack something above it, as being not a space weapon, although I suspect that the time will come when we will launch space weapons from earth bases. But I am referring here to the presently envisaged air-defense systems. And we are really talking in space technology about any kind of object or instrumented object of investigation or manned object that is going to remain for a considerable time outside the sensible atmosphere.

And, some defense, therefore, must be developed against these techniques which will be quite different from those used for aircraft.

It is going into and staying within that portion of outer space where aerodynamics don't operate, where you cannot use airfoils as control surfaces.

That is what we think of as the outer-space area.

Mr. BROOKS. Let me ask you this question, then.

You work with the NACA?

General MEDARIS. We cooperate with them. We have people on some of their subpanels; that is correct.

Mr. BROOKS. Is there any overlapping of jurisdiction with your work in NACA?

General MEDARIS. There has not been to date; no, sir. NACA has under its control certain resources that we have used in programs ourselves, such as the wind tunnels that they have. We have asked the NACA to do a few investigative projects for us which they have done. But that has been asking them to do it for us against our projects and with our money.

Mr. BROOKS. Is there any overlapping of jurisdiction between that and ARPA?

General MEDARIS. Mr. Congressman, I am going to have to beg off on this one because it gets a little more complex than I have been able to follow.

Frankly, I do not know. It does not impinge on my work at the moment, so I really don't know how much overlap there might be.

Mr. BROOKS. Well, the Advanced Research Projects Agency is a new agency and it would be a little different.

General MEDARIS. That is right.

Mr. BROOKS. That is all, Mr. Chairman.

The CHAIRMAN. General, can you give us any information, without violating any classified obligations, as to how far we have progressed in the field of intermediate and intercontinental ballistic missiles, having in mind the relative situation with reference to the progress of the Soviet Union?

General MEDARIS. There are some known facts, Mr. Chairman, that can be given openly.

It is a known fact that the Soviet Union has successfully fired an intercontinental ballistic missile over the full intended range.

The CHAIRMAN. What is that range?

General MEDARIS. In excess of 3,000 miles.

I would not want to define it exactly. We don't know exactly its range capability, but we know pretty well what it is.

In this sense we know that, of course, they are ahead of our intercontinental missile program. Those programs belong to the Air Force and, as a basic principle, I would rather have people answer for their own programs.

I do not consider myself in a position where I should comment on somebody else's job.

The CHAIRMAN. In the field of intercontinental ballistic missiles and intermediate missiles, is the Soviet Union way ahead of us?

General MEDARIS. I think there is no question about that; they are definitely ahead of us.

The CHAIRMAN. Is there any idea how far ahead they are?

General MEDARIS. It is a very difficult thing to measure. I think we have had more difficulty unsnarling some comments that have been made on that subject than anything else. Because how far ahead they are has to be handled in 1 of 2 ways, Mr. Chairman. Either we have to take point by point the various technical areas and relate what they know that we don't, or what they have done that we have not done, or if you want to put it in other terms, it is a question of how fast they are moving and how fast we are moving.

If they are still moving faster than we are, then they are an infinity of years ahead of us because we will never catch them.

If we are moving faster than they are, how long it will take us to catch up will be determined by how hard we work.

The CHAIRMAN. Can you give us any information as to the progress made by the Soviet Union—we hear about antimissile missiles but I will confine it to anti-intercontinental bombers—as a defense against our intercontinental bombers?

General MEDARIS. They have devoted a great deal of energy for quite a few years to an extensive system of their defense against such planes. I would not feel free to go into details as to the extent of their capability and I am sure that the committee could get that information from the Intelligence people in a briefing.

The CHAIRMAN. Is it your opinion that in the troubled world today it is vitally important that at all times we be in a position where although we are committed to a policy of nonaggression, that we be able to retaliate in case of an attack?

General MEDARIS. It is my conviction, Mr. Chairman, that we cannot afford under any circumstances to let ourselves get into a position where a single unexpected massive strike would completely cripple our resources to the extent that we could not deliver very heavy punishment on the initiator of that type of aggression.

I believe that so long as we stay in the position where, regardless of what he does, there can be a strikeback, and regardless of the conditions of his defense, there can be a strikeback, and an effective one, I don't think it will occur as long as we stay in that position.

The CHAIRMAN. In other words, the law of self-preservation?

General MEDARIS. That is right.

But the deterrent force has to be visible. It has to be known to exist and it has to be effective and capable of doing its job regardless of the other fellow's defenses.

The CHAIRMAN. The more people realize that, and with a sound public opinion supporting such a policy, the better it will be for our country?

General MEDARIS. Naturally.

The CHAIRMAN. In other words, it will be a sad day—I would never admit defeat, but it would be a sad day—if the day ever arrived when they could hit our targets and we would have difficulty hitting their targets?

General MEDARIS. Yes, sir; because this is always a temptation to

anybody who is grasping for power. If they have the capability of doing an effective unilateral act and not being punished for it, they may overcalculate what the results will be and if they think they can win in one heavy strike, it is a temptation to do so.

The CHAIRMAN. And even more than power when they are dedicated to world revolution and world domination?

General MEDARIS. That is correct.

The CHAIRMAN. That is quite an important key at this time, is it not? That particular situation is something that we cannot under any conditions ignore?

General MEDARIS. I feel that we must not ignore it. If his technology advances and his capabilities and the capability of any hostile military power to strike us increase or change, we must change and vary our abilities to meet it and strike back.

So that we cannot get behind. We must stay ahead.

The CHAIRMAN. And the American people must realize that they have to pay the price and make sacrifices?

General MEDARIS. It is an untidy world and at the moment we have to live with it.

The CHAIRMAN. And in connection with this important activity the American people had better expect failures in the making of tests, but out of failures come future successes.

In other words, they cannot quibble over the fact that something is tried and may not be a success at a particular time?

General MEDARIS. No, sir; because if you don't try you will never do anything. If the only thing we tried to do were those things that we knew enough about and knew so thoroughly that we could always succeed the first time, you could be sure that we were not trying enough, that we were not far enough out. Any progress is based on failures as well as successes. It has to be

The CHAIRMAN. Mr. Natcher?

Mr. NATCHER. In order to present some of the problems concerning outer space and exploration, our chairman, Mr. McCormack, has introduced a bill, H. R. 11881. General, have you had a chance to read that bill?

General MEDARIS. Yes, sir; I have.

Mr. NATCHER. This bill makes certain provisions concerning outer-space exploration, one of which is that a civilian agency is to exercise control over aeronautical and space research sponsored by the United States except insofar as such activities may be peculiar to, or primarily associated with, the weapons systems or military operations, in which case the agency may act in cooperation with or on behalf of the Department of Defense.

How do you feel about that provision, General?

General MEDARIS. As the provision is written, Mr. Congressman, it adequately covers, I am sure, the desires of the chairman and it is well expressed.

I cannot comment on the legal language. The operation of any system of this kind is going to depend on good people making it work.

Mr. NATCHER. General, do you not feel that activities such as the ones provided for in this bill should be under the control of a civilian agency?

General MEDARIS. I have only one problem, Mr. Congressman, and that is that neither this bill nor succeeding events can completely define in all cases where this division point is.

Now, if it develops in such a way that there is a very closely knit cooperative effort between this agency and the Department of Defense, and a mutually supporting arrangement, so that there is no quarreling or quibbling over the shadow zones in a thousand places, if it is a question of where it is going and into what it is going to develop, then there is no reason why it could not be an effective answer.

On the other hand, as I say, the only things that trouble me are the fact that I find it very difficult in my own mind, with assurance, to divide out the scientific, the peaceful, and the military, in terms of any kind of intensive forward research.

This does not mean that this kind of organization cannot do it effectively. It means that it is going to require the close cooperation of well-intentioned people.

The CHAIRMAN. As I interpret your mind, would it be a fair interpretation broadly to say that, while you believe in a civilian agency in the world of today and the immediate future, the military should not be put in a subordinate or secondary position?

General MEDARIS. I am not thinking in those terms, either, Mr. Chairman. It is not a question of who is on top and who is on the bottom.

We in the military are dedicated to the principle of civilian control of our military affairs. We believe that is a proper and essential basic part of our system of government

We have no quarrel with that. What worries me, Mr Chairman, is that it has been difficult in the past under military programs, recognized as weapons programs, to be able to justify and secure the funds and support for the type of forward-reaching research which in its turn will develop new weapons systems.

I am somewhat fearful that the more the scientific and military are divided, the more difficult it will be for us to really go forward in the research area in those things that must be done now if the next generation of military weapons will be as good as those which we may meet on some field of battle. This is my fear.

Mr. NATCHER. General, I have here a copy of the report from the Special Committee on Space and Astronautics of the Senate It appears that you testified before the Senate Preparedness Subcommittee sometime in December of last year.

According to a summary, which by the way, is not a direct quote of your testimony, but a summary of your testimony, it states as follows, and I will quote:

> I do not agree with the recommendation for an independent agency. One individual must be charged with responsibility.

That is the end of the quote in this summary, which appears to be a summary of your testimony.

General, is that what you feel about this matter?

General MEDARIS. I reached that conclusion after long consideration and study of the problem and I have been given no facts to make me change my mind.

Mr. NATCHER. So you are now of the opinion that one individual should be in charge and that it should not be an independent agency. It should be under the direct control of the Department of Defense. Am I correct?

General MEDARIS. If I may, I would like to expand on my remarks at that time.

Mr. NATCHER. You go right ahead.

General MEDARIS The point there in consideration is where are the resources with which these things are to be carried out? The present resources that are available in this country to carry us forward in the space-science area are in turn almost all involved in some type of military work as well.

Coordination is a difficult matter. Perhaps it is my military background when I say that a single person in command has more virtues in most operating fields than does a lot of cross-coordination.

And the ability to use the resources wisely, as between the military requirements, the space requirements and the science requirements, and to carry them forward in team, using again the resources in common because this is where the work has to be carried out, this is where the resources exist and the teams exist, is going to be quite difficult with divided direction based on the division between science and military purpose.

This was the reason why I made that statement and why I felt that way about it. It is going to be very difficult.

I will say again, as I said initially, the organization can work, but it is going to take very good men working in very close coordination to keep us from having some difficulties by having to always decide which area does the thing, and in having a requirement for coordination interdepartmentally in order to assure us that we have the maximum benefit from science and the military and vice versa, that military work lends its best support to science.

Mr. NATCHER. General, do you have in mind the Manhattan project when you say a one-man organization?

General MEDARIS. No, sir. I am satisfied with the way ARPA has been doing. Roy Johnson tells me what to do and I go about it. I am really happy.

Mr. NATCHER. So you say no independent agency. Then who would head this proposed organization that you have in mind, General?

General MEDARIS. I was talking about having a man who was held responsible for the general field and who was working within the Department of Defense, this because of the necessary coordination in the use of resources between weapons projects and science projects.

And who would head it is up to someone else to decide.

Mr. NATCHER. In other words, in your mind there is a clear line of demarcation and a distinction should be made as between civilian control and military control from the standpoint of this particular organization. Am I correct in that, General?

General MEDARIS. I would assume this in the case of both this as well as our weapons organizations, that they would be subject to civilian control and that they would be civilian operated.

I have at no time proposed that this should be a military operation, controlled and directed by a military man. I have not proposed that. I do not subscribe to that.

Mr. NATCHER. What you do have some difficulty with, in your own mind, apparently is the question of an independent agency being in charge?

General MEDARIS. That is correct, and being outside the Department of Defense, which increases the interdepartmental coordination requirement.

Mr. NATCHER. Now, General, is your research and development based upon military requirements?

General MEDARIS. Our research and development, because of policy and funding and budgetary considerations, has always been based primarily on military requirements This does not mean that we have not done some basic research, always in the hopes it might turn up something to contribute to our principal mission

But this has been the result of an operating method, shall we say, an overall national approach to the problem, rather than what we would like to do.

I think the services generally have felt for many years they should be doing more basic research and not quite as closely limited to that which directly and immediately contributes to weapons systems. I know I feel that way.

Mr. NATCHER. Would it be possible for an organization such as yours to continue to function efficiently under a civilian agency which would permit broader research in purely scientific fields, which have no military benefit at the present time, or value?

General MEDARIS. It would neither be efficient, nor proper, nor easy to do, to have it do so exclusively. My command is not that kind of a command. It has a great many balanced resources. It must maintain the primary responsibility for providing the Army with its most modern weapons in the missile field.

However, I find no difficulty in working for two masters with respect to my projects. I have only one commander in the chain of command. This is simple.

But as far as my projects are concerned, I have no trouble working for two masters. I am doing it at present. It creates no more problem than it does for a big civilian corporation to have contracts with 3 or 4 people. It is the same thing.

Mr. NATCHER. Thank you, Mr. Chairman.

The CHAIRMAN. Mr. O'Brien.

Mr. O'BRIEN. I have no questions, Mr. Chairman.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. General, pursuing the same line of questions just a bit further, actually is it your feeling that possibly we may be getting too many committees and too many commissions involved in this overall space and missiles program?

General MEDARIS. It is a possibility, certainly.

Again I say this is going to depend entirely on the quality of the people who work it out and how well they do it.

As I understand the bill, there is a Director who has full authority. He is to be the Director of the Agency and as such does not have to wait for his committee to act on what he is to do.

That being the case, we have the possibility of its reacting rapidly and of coordinating closely and carefully with the Department of Defense.

So there is no reason why it will not work.

Mr. SISK. In reference to the questions by the gentleman from Louisiana a few minutes ago, regarding ARPA, do I understand that your answers were to the effect that ARPA would have full control of contract negotiations, with reference to either the Army, the Navy, or the Air Force, in connection with outer space activities and matters of this type? Is that correct?

General MEDARIS. The way ARPA is operating at present is that they negotiate with us and with other agencies of the Government and outside the Government with respect to carrying out certain projects. And having reached a conclusion that certain projects should be done and having negotiated approximately what the budget is going to be, they send me an order and some money and with that I go to work.

In the progress of that project our technical directors are in close contact continuously and freely with Dr. York and his people in the technical side of ARPA and follow their guidance in carrying it out.

Mr. SISK. What I am attempting to do is to pin down their authority in the field of the letting of contracts. Otherwise, of course, we would have some five agencies possibly letting these contracts.

That is what I was trying to determine. Whether ARPA under its present operation actually has the full control so that they become the guiding agency and we do not have this great spread throughout many agencies in the letting of these contracts.

General MEDARIS. This is correct, they have the control.

Now, the point is, in the matter of letting contracts this can be done in several ways and to date ARPA has assigned its projects in terms of its contracts to existing agencies of the Government which in turn make such subcontracts to support the project as they need to.

They have not yet to date, although they have the authority, I believe, made independent contracts in terms of a regular business contract, a contract obligation document, with civilian companies. They do it much more easily the other way because all of us who are in these fields must have the structure required to handle that kind of contractual action, people to administer those contracts, the negotiators, the legal support for them, and everything else.

We have contracting officers. It is their normal business. They assign it to us and as a part of carrying out of project we let the contract to support it.

We do part of it ourselves and part of it is under contract.

Mr. SISK. At present it is working smoothly?

General MEDARIS. From my standpoint it is working just fine.

Mr. SISK. Now, let me ask you to comment, General, as between the NASA and ARPA. For example, if the pay differential is approved, which I think you are familiar with, I am wondering what your comment might be with reference to its resulting in NASA becoming the controlling agency. Do you have any comment to make on that?

General MEDARIS. I do not see any real basis here for, shall we way, a struggle for power There is an attempt to spell out the different areas of responsibility as between NASA and the Department of Defense. The only difficulty lies in the fact that there is going to be a considerable shadow zone to be resolved, but certainly it does not provide any basis which would lead to a, shall we say, kind of interbureau struggle of who is boss.

Mr. SISK. Let me ask you this. I refer to the pay differential, if it should be approved. Now, is it probable that over a period of time NASA would probably wind up with all the good talent and ARPA, to some extent, would be downgraded?

Now, I am just speculating I am only asking if you have any ideas along that line.

General MEDARIS All I can say is everybody does not chase the almighty dollar. Of course, if it gets to be $50,000, maybe they will, but there is no restriction on the commercial organizations of the country and their pay scales and they have not stolen my people yet and I do not think they will.

Mr. SISK. I appreciate that statement, General, because actually in many instances I think we have some, in fact we have a lot of good devoted people who, let us say, do not put the dollar sign first, and I thank God we do have this kind of people and may we continue to have them.

But, of course, this would become a pressure, I feel, to some extent, on one agency versus the other, if there were extreme differences.

General MEDARIS. ARPA, of course, at present, is not operating as an agency. It is operating as a directorate. It has very few people, apparently adequate for its needs, but it depends upon those of us in the business all over the country to do its work for it.

So in that sense it is not a competitive proposition. I will be perfectly frank with you. I do not know whether under this bill, if this bill is passed, I do not know whether ARPA is still in business or is not. I do not know, sir.

Mr. SISK. Let us change the line of thought just a bit, General I want to ask you a few questions with reference to what your opinion is regarding what we might term slowdown or stoppages in your program that may have affected it in the past.

Let me say this. That we do not desire to engage in recrimination and going back. We want to look ahead, but as these things may have affected the program in the past, I think it is in the interest of this Committee to see that they do not occur in the future.

First, for example, I would like to refer back to Project Orbiter. What, in your opinion, was the effect of your not being able to proceed with Project Orbiter? Will you comment on that, General?

General MEDARIS. Sure. If we want to play Monday morning quarterback, it is real easy to say how the game should have gone on Saturday, but at the time the decision was made between Project Orbiter and Project Vanguard, I am quite certain that the people on the committee who made the recommendation were doing their honest best to make an honest decision.

The fact that it turns out that Orbiter, if continued, would have come to a successful conclusion earlier, is one of these real "iffy" things that really lands into the Monday morning quaterback area.

Mr. SISK. I appreciate we are speculating and using a lot of "ifs", and so on, but I am concerned with statements that have been made by a great many people over some of the reasons for, let us say, one agency being preferred over another in some of the decisions in the hope that we may preclude such decisions in the future.

Now, we have had testimony that you could have launched a satellite, put a satellite in orbit, at least 2 years earlier, or approximately thereabouts, had your team been given the go-ahead.

Now, do you agree with that?

General MEDARIS. Not that long. The earliest that we could have launched a satellite, had we had the project direction and been told to do so, would have been about a year and 3 months, about 15 months earlier than we did launch a satellite. This happens to be a fact that proves itself.

The question of whether it was intended to be that way, or not, is another question.

In other words, I am quite sure that the people who made the decision did not intend to delay the situation, but we were dealing then with the claims of two groups, one of them saying they could do this, and the other saying they could do that.

It turns out that one of them was a little better and knew what they could do and sooner than the other.

We cannot go back and say that this was any question of trying to slow down a program. It was merely a mistake in judgment which everybody is going to make.

There are some tough decisions to be made, Mr. Congressman, and I, for one, will never expect all the decisions to be made right. We don't have this kind of people. We are going to make some mistakes.

Mr. SISK. I appreciate that.

Now, in your testimony before the other body last winter, there were some questions with reference to the type of engines that are needed, the thrust that is required, and so on. In some of your testimony, as I recall, you made a statement to the effect that an engine of something over 200,000 pounds thrust was recommended, but it was turned down.

Are you in a position, or would you want to comment, as to why that was turned down at the time? That was in 1956.

General MEDARIS. The report of the committee that acted on it and recommended to the Secretary of Defense simply said that there is no specific use for this engine demonstrated and therefore we cannot recommend that the money be invested.

Mr. SISK. That brings us down to the reason and the background for the questions.

Now, are there engines of that type now being worked on and in general do the agencies in control of this program, in your estimation, realize the need, even though there may be some question of its specific use at the moment?

General MEDARIS. I think without question that there is now a pretty general realization of the requirement for higher thrust engines. There are some very substantial differences of opinion as to how it should be achieved the earliest.

Again I am not prepared to say what whoever's judgment is followed is going to be infallible. We may make a mistake on this one, too. I don't know.

Mr. SISK. Let me ask, General, and this is up to you whether you want to answer these questions. I realize some of them may get into the realm where you prefer not to answer them.

Are we actually doing research and development work at present on engines, for use in future vehicles or weapons, to the extent that you feel we should?

General MEDARIS. After you added that last phrase, I have to say no.

Mr. SISK. That is exactly the information I am interested in.

General MEDARIS. But this in only my opinion, Mr. Congressman.

Mr. SISK. I appreciate that, General. I respect your opinion.

From the things I have heard in the past, I have the highest respect for your opinion. That is why I am asking for it.

Now, I referred to December, when you appeared before the other body. This, I understand, is not a quote, but a summary, with reference to the overall program, referring to the Jupiter program and Redstone missiles and flight-test vehicles and so on, and in summary of what you say.

"The program is proceeding at optimum speed now. The future roll-on of the program is half the level it should be."

Now, has anything occurred since that time, General, that would cause you to feel differently today?

General MEDARIS. I am sorry, but I cannot put myself in context with that summary. I don't quite get the relationship to my testimony there.

Mr. SISK. As I state, this is not a quote This is merely a summary setting forth generally some of the ideas.

General MEDARIS. Does the summary refer to the Jupiter and Redstone programs?

Mr. SISK. Let me read the entire paragraph:

> The Jupiter program was impeded because there was great debate over whether the Army needed it or not, and this took time The rate of output was limited. Half the amount recommended was approved. The apportionments were—

and here is the quote—

> "always protested by reclamas."

I thought if you wanted to comment on that quote, I would appreciate it, but if you do not, why, I will respect your decision.

General MEDARIS. I will clarify the quote.

Mr. SISK. The paragraph ends here:

> With the inauguration of the Jupiter program and requirement of the Redstone missiles, flight-test vehicles to support the firings of Redstone were accelerated. The program is proceeding at optimum speed now The future "roll-on" of the program is half the level it should be.

I am curious to know whether, in general, you still agree with that.

General MEDARIS. This refers to the production of Redstone missiles for field use and the situation has not changed.

The Army still would like to produce them somewhat faster than we have been able to do.

Mr. SISK. What can this committee, or the Congress, do to take care of that situation? Do you have any recommendations that you would make at this time?

General MEDARIS. Sir, I am afraid this is a matter between us and the Department of Defense I do not know where the question could come in specifically to the Congress without going as deeply into the subject as we all must in trying to decide where each piece of money must be spent and what weapons are to get the benefit of the budgetary support.

I don't know who is right. The Army feels that we would like to have more of them than we are able to produce at the present time. Defense says maybe we don't need any more. Who is right, I don't know.

Mr. SISK. It is my understanding, generally, that it is your opinion that we cannot completely divorce, let us say, satellites from the ballistic missiles, that to divorce them would be to impede the progress of both and that as such they, at least in the immediate future, have to be tied closely together.

General MEDARIS. The missile art has provided the initial earth departure systems, the missile systems by which satellites can be gotten up out of the earth's atmosphere and into orbit.

For the foreseeable future, until somebody finds some other method, this appears to be the one that will have to be used for some considerable years to come.

As long as this is true, anything that is done in the military missile field will have a possibility of contributing to the space field.

So if that contribution is withdrawn, the cost of pure satellites as such, not resting on military requirements for the development of basic thrust hardware, is going to be pretty high if you do them entirely separate.

In fact, I might say it is going to be awfully high.

Mr. SISK. To sum up this question and going back, then, to my first statement, General, do you feel that you are being held up in any way, or are being precluded from proceeding at a rate in the development of the ballistic-missile program as it refers to satellites and all the other things that go along with it?

Now, we referred to the "ifs," if with reference to Orbiter and also in the 1956 test, when I understand certain people came down to see to it that the last stages were not loaded and so on, to make sure that you did not orbit. Now, I want to know if anything is being done today by any agency which is precluding the progress which I think every one of us as Americans is definitely interested in?

General MEDARIS. It is a very large question, Mr. Congressman. I can only answer it this way:

There is nothing being done to inhibit those projects which have been determined to be necessary in the immediate future and of which we have been assigned a proportionate share.

My major concern at the present time continues to be devoted to the next satellite project. I have to say I do not believe that we are looking far enough ahead and starting those things which will be essential to support the kind of things we ought to be doing 5 years from now, the stage ahead of the development of a final weapons system or a final satellite system.

The fundamental developments based on advances in the art which will provide us with more flexible engines, engines of higher efficiency by using more advanced fuels, the very advanced types of guidance systems that will be needed in outer space that are not exactly the same, but can well peel off their missile guidance systems and to which missile guidance systems must contribute greatly, there are a dozen fields of activity that in my opinion are being pursued vigorously which as they are pursued today would not tell us how you will come out in terms of what you will finally do with that product, but if intelligently selected 5 years from now will give you the building blocks by which we will be doing the thing which I think we ought to be doing 5 years from now.

This is one place we have not got into as yet. I think there is every intention of getting into it and I would not have this committee believe that anybody is willfully staying away from it, or anything of that sort.

There are a lot of loose ends to pick up here. We have to look at the position and recognize the fact that, shall we say, 7 or 8 months ago there were not too many people who took this business seriously.

Those of us who did could get qualified as crackpots in a great many places in the country without any effort at all.

All of a sudden people realize that it is a serious business. You cannot pick up all the loose ends and get it all straightened out and then on the track in a few months. It is too big a job.

I hope as rapidly as it can be resolved those things will be going forward. This is my only discontent at the moment, that I would like to be in some things that will lead to the next step in the business.

Mr. SISK. General Medaris, I certainly appreciate that statement on your part. I think the very creation of this committee, the very fact we are sitting here this morning, is because of, let us say, a little revolution in our thinking and a little better understanding that we are in the Buck Rogers age, so to speak, and we are going to have to wake up to that fact.

I know that this committee is desirous of trying to loosen itself from our earthbound tendencies and to be able to make the break. I appreciate the fact that we have men like you who have that vision and that was the point I was making. I think we are desirous of doing the things that will grant to you and others the ability to go forward and plan for 5 to 10 years in the future, to get the necessary hardware and to develop the other things that are necessary without being able to pinpoint today exactly what engine or piece of hardware is going to be used in a military way or in another specific way.

Is that not generally the need that you have?

General MEDARIS. That is right; yes, sir.

I have such confidence in the basic system of government and the philosophy of government of our people, that I believe fundamentally that if the actions of the Congress and committees like this make clear that the people whom they represent are behind this sort of thing, and are willing to support it, then I feel quite sure that our system will produce the kind of results you want.

This is why I am gratified to see this kind of interest.

Mr. SISK. One other thing I would like to have you comment on, General, is this. The day before yesterday Dr. von Braun mentioned the possibility, and as I understand him, what he felt to be the advisability, of putting a man into space some 150 miles. I am sure you are familiar with the statement because there has been some comment here and there about it since yesterday.

It is my understanding, and I am simply quoting the newspapers, because I did not hear the statement, that there was something indicating that, possibly, that was kind of like shooting a woman from a cannon, or something of that kind.

Now, do you feel that has value, or would it be, let us say, more characterizable as a stunt?

General MEDARIS. No, sir; I have not yet and I will not at any time propose to the Government that it spend its funds in support of a project that has no useful purpose or no proper end point to go to.

There are plenty of things to be done that are spectacular that are not stunts, so we don't have to resort to things that are stunts.

The project when it is understood definitely is not a stunt. It is a necessary and essential prerequisite to the careful step-by-step advance of our ability finally to transport people by missile.

I put this even independent of any outer space action in terms of satellites. I foresee a positive requirement for being able to put people on a specific spot in small numbers by missile-borne means.

If we are to do that, this particular experiment is a definite way station on the route we must follow.

Mr. McDonough. Do you believe that will be valuable, General?

General Medaris. I believe it will be very valuable.

Mr. McDonough. That is about the same thing that Dr. von Braun said, but I do not believe it was in Dr. von Braun's mind to interpret this proposal as a stunt.

Dr. von Braun said, if he were given the go-ahead right now he could shoot a man in a capsule in the nose of a rocket 150 miles into space and return him safely.

Then Dr. Dryden came along and said that there were at least 200 such proposals and for the reason that there were 200 such proposals they have not picked any one that they would proceed to put their effort to.

Now, what you have just said is that you want to put a manned missile into space, which would be a valuable thing for us to do, to find out what we can and if it can be successfully operated.

Mr. Sisk. If my colleague will permit me, I will yield back the balance of my time.

The Chairman. General, you will have the opportunity of editing your testimony and elaborating. In connection with that, I would appreciate it if you would elaborate on the uses for peaceful purposes that these activities could bring about, if successful, from the standpoint of the military necessity as well.

So you have the permission to edit your testimony and the Committee would welcome any elaboration on your part that you think is pertinent to the Committee's duties and responsibilities. Mr. Ford.

Mr. Ford. General, may I ask a question or two to clarify some questions that were asked earlier?

Any alleged criticism of the production schedule of Jupiter, in testimony given in December, conceivably may relate to the designation as to whether Jupiter should be put into exclusive production or whether Thor should be put into exclusive production, or whether both should be put into joint production.

Is it fair to say that criticisms of a production schedule would not be the same if you were putting both into production?

General Medaris. That is correct.

Mr. Ford. In other words, sometime in late November or early December, the decision was made to put both into production at a reduced rate for each. Is that correct?

General Medaris. That is correct. Yes, sir.

Mr. Ford. It is also fair to say, I think, that if one, rather than both, had been put into production, obviously you would have needed a bigger rate of production for the 1 rather than for 2.

General Medaris. That is true, Mr. Congressman. The production rate to which I referred in this case, however, was for Redstone, not for Jupiter.

Mr. Ford. It did not relate to Jupiter?

General Medaris. It did not; no, sir.

In my testimony at that time I said almost exactly what you have commented on now, sir, that we recognize the problem of decision, that that decision had just been made before I came before the committee

at that time and this appeared to have resolved itself as far as Jupiter is concerned.

Mr. FORD. Both Jupiter and Thor are now in production. They have been financed and, as I understand it, are on schedule. Is that correct?

General MEDARIS. I can only comment for Jupiter. I never answer for the other fellow's production schedule. Jupiter is on schedule.

Mr. FORD. Which envisages units in the field sometime late in 1958?

General MEDARIS. That is as the Secretary of Defense has so announced and we support his announcement.

Mr. FORD. I think it would be helpful for the record—I am sure you do not have the information here at the present time—but could we have from some source a list of the individuals who made the decision between Orbiter and Vanguard and the date their decision was submitted to the Secretary of Defense?

As I say, you may not have the information here, but if somebody from the Department of Defense could provide that for the record, I think it would be helpful.

General MEDARIS. Mr. Congressman, I will pass that to the Department of Defense. It is appropriate that the Defense Department answer that because all the agencies concerned are under the Defense Department.

(The information above referred to follows:)

The Assistant Secretary of Defense (Research and Development) advised the Secretary of Defense that, as indicated by the studies, a small scientific satellite weighing 5 to 10 pounds could be launched into an orbit about the earth employing an adaptation of existing rocket components. If a prompt decision were made to embark on such a program, he advised, the United States would probably be able to launch and track a satellite of this kind within the period 1957–58. Subsequently, the Secretary of Defense was directed to develop the capability of launching a small scientific satellite by 1958 under the auspices of the International Geophysical Year. Within the Department of Defense the responsibility for coordinating the developmental program and the scientific aspects involved was given to the Assistant Secretary of Defense (Research and Development).

The first Defense task was to develop a specific technical program for the launching vehicle from the several major possibilities afforded by the missile work already in process in the military departments, the problem being that of selecting the alternative with the best chances of success within the period of the International Geophysical Year. To advise on this important selection, an Advisory Group on Special Capabilities was formed, with a membership consisting of 8 outstanding civilian consultants, each having considerable experience in rocketry or associated technical fields, 2 experts recommended by each of the military departments and 2 selected by the Assistant Secretary of Defense (Research and Development), the instructions to the group called for a review of the various satellite plans and programs and a recommendation of an equipment program by August 1, 1955, including suggestions with regard to the governmental and industrial organizations where the different phases of the program might best be carried out and a consideration of the impact of the recommended program on weapons development projects.

The White House announced on July 29, 1955, that plans were going forward for the launching of small unmanned earth satellites as part of the United States participation in the International Geophysical Year. At the same time, the Chairman of the United States National Committee informed the International Committee sponsoring the IGY of the inclusion of these plans in the United States program.

The Advisory Group on Special Capabilities submitted its report to the Assistant Secretary of Defense (Research and Development) early in August 1955. In brief, it recommended the development of a scientific satellite vehicle in 2 phases: (1) An immediate program for achieving a 5- to 10-pound satellite on

orbit during 1958; and (2) a program to launch a satellite vehicle of significantly larger payload and higher orbit at some future date. Noting that on technical grounds the use of the motor of the intercontinental ballistic missile would unquestionably provide the greatest performance margin, the Group disqualified themselves on the question of whether this could be accomplished during the period of the International Geophysical Year because of uncertainties with respect to the degree of interference with the ICBM program that might be tolerated and uncertainties regarding the validity of the current ICBM schedules. The majority of the Group recommended the use of the 3-stage launching vehicle proposed by the Navy; a minority recommended the use of the Redstone missile as the basis of a 4-stage launching vehicle, as proposed by the Army. The Group further recommended that, in any case, studies of the use of an ICBM booster should be pursued as a responsibility of the Air Force.

Through the Research and Development Policy Council, the Assistant Secretary of Defense (Research and Development) sought the advice of the senior civilian and military officials responsible for research and development in the military departments in regard to questions of interservice cooperation and the possibility that the scientific satellite might interfere with weapons programs. After extensive deliberation, including discussion with the Chairman of the Advisory Group on Special Capabilities, the Policy Council recommended, and the Assistant Secretary agreed to, the selection of the Navy proposal for a three-stage launching vehicle based on the Viking and Aerobee-Hi rockets. [The Army members of the Policy Council did not concur in this action.] The Deputy Secretary of Defense approved this proposal and issued a directive on September 9, 1955.

In summary, the Air Force proposals for launching vehicles based on ICBM motors were rejected because of uncertainties regarding the possibility that the weapons-development program might be delayed as a result of combining it with a scientific satellite program. The decision to use the Navy-proposed Viking approach instead of the Army-Navy Redstone proposal was based primarily on the technical recommendations of the Advisory Group on Special Capabilities. To a degree, this technical judgment was founded on the fact that a 3-stage launching vehicle appeared to be inherently less complex than a 4-stage vehicle and, further, that the spin-stabilized second stage involved in the 4-stage proposal had not yet been adequately flight tested. Also, the Army-Navy proposal involved some reliance on the Redstone weapon program and possibly some competition for diversion of Redstone engines intended for weapons.

MARINE CORPS

Member: Brig. Gen F. M McAlister, Assistant Chief of Staff, G–4, headquarters, United States Marine Corps, room 2126, Arlington Annex, Extension 41969.

Mr. FORD. I would like to pursue what your command relationship is in three specific fields with ARPA at the present time.

Let us take projects that I know your command is working on, the Pershing missile, Nike-Zeus, and the lunar probe projects. The Pershing missile project is strictly a military weapon?

General MEDARIS. That is correct.

Mr. FORD. You get your orders for the prosecution of that project from whom?

General MEDARIS. From the Army Missile Committee, chaired by the Secretary of the Army.

Mr. FORD. ARPA itself has no control over that particular project?

General MEDARIS. It is not within ARPA cognizance.

Mr. FORD. The Nike-Zeus project, from whom do you get your direction in that area?

General MEDARIS. The Nike-Zeus project was in the original assignment by the Secretary of Defense to ARPA.

Mr. Holliday, the Director of Guided Missiles, was the custodian of that authority during the period that ARPA was being formed.

It is my understanding there is a discussion at the present time whether or not that should be taken up by ARPA or whether or not it should remain with Mr. Holliday.

In any case, it is a military project. So far as I am concerned, wherever it is directed in Defense it will be worked in collaboration with the Army Missile Committee under the Secretary of the Army.

Mr. FORD. So as of the moment, ARPA itself does not have control nor does it give you direction in reference to Nike-Zeus.

General MEDARIS. Not at this time; no, sir.

Mr. FORD. Now, the lunar probe projects.

General MEDARIS. That is entirely under ARPA and my directives come directly from ARPA.

Mr. FORD. As I gather the function of this new agency, NASA, you would work with them, for example, on projects like the lunar probes.

General MEDARIS. That is correct, sir.

We would work with and for them; yes, sir.

Mr. FORD. But in the area of a project similar to a Pershing missile, you would still get your direction from the Department of Defense?

General MEDARIS. That would be strictly military and would stay within the Department of Defense; yes, sir.

Mr. FORD. Probably the Nike-Zeus program would fall in the Defense area, would it not?

General MEDARIS. Undoubtedly, it is a weapons system.

Mr. FORD. For the benefit of the committee, could you comment on the military aspects of the satellites?

General MEDARIS. This, of course, has been a very greatly debated point. I rest my own conclusions in two areas:

First of all, I think it is generally recognized that satellites at present offer the best means, the best known means, for reconnaissance under conditions when manned aircraft may be very greatly impeded, if not prevented from carrying out their missions.

This, however, is a responsibility of another service and I will not pursue it further.

The Army's interest in satellites from a military standpoint falls into the general areas of communications as the most efficient communications relay stations that we know could be developed. Weather, which is, of course, of enormous importance to a ground field commander, to know what weather conditions he will confront against a planned operations sequence; and we are quite confident that the science of meteorology can be advanced to the status of an exact

science with considerably longer range capabilities if satellites are used to acquire proper information.

The Army has an interest in space from a military standpoint as an intermediate part of the transit route, shall we say, in our logistics problems in the transfer of personnel and supplies.

In the scattered, isolated, and fast-moving battlefield of the future, the ability to transport very valuable and badly needed supplies to exact areas without the capability of their being stopped will become of tremendous importance in my opinion.

Missiles provide that resource. The missiles themselves, of course, go part of the way through space and the reentry problem, which is part of the space problem, is in that field also.

This is the Army's interest.

From a personal standpoint I have the unhappy conviction that unless something happens to change the basic psychological makeup of man he will find some means to generate an argument in any place that he can handle himself and can exist; and it is entirely feasible and possible in my mind that we get into a position where the military value of the satellite even for relatively passive purposes, as I have mentioned, becomes recognized immediately the question comes how can we stop them or get them out of there. Maybe we find the best way to do that is to get up there with them and chase them around a bit, which appears to be about the only way you can really counteract a satellite, to be able to take knowledgeable action against it, which means a manned satellite of some kind.

You get in a fuss and you send somebody up to protect your satellite and the first thing you know you have a first-class war on your hands

Mr. FORD. I gather from your comment that there is feasibility to an antisatellite satellite weapon.

General MEDARIS. Yes, we think so. We have several concepts of what such weapon should be. It has its problems.

Inevitably it leads you to the conclusion that there is an easier way to do it if you could send a man along. This is one of the reasons why I follow this chain of thinking, myself.

Mr. FORD. Are we working on feasibility studies on an antisatellite satellite project?

General MEDARIS. I might say as far as feasibility studies are concerned, I have a small corner of my shop that does nothing but work in any direction we think is profitable.

I think the answer to your question in that area is definitely yes.

Mr. FORD. In reference to the bill, General Medaris, a provision on page 3 says:

> No more than 8 of the members of the Board shall be designated from appropriate departments or agencies of the Government of the United States, including at least 1 who shall be from the Department of Defense.

As you know, the total membership of the Board is to be not more than 17; 8 from the Government, including at least 1 from the Department of Defense, and the remainder from outside the Government.

Do you feel that one from the Department of Defense is adequate to represent the views of the military on such a board?

General MEDARIS. In view of the fact that the Director of this agency is the operating authority and the Board is advisory, the real problem from the standpoint of representation is in the Department of

Defense. There comes this problem of coordination that I have mentioned. Provided he is adequately armed with the facts by supporting services and entities of the Department of Defense, one man is enough to bring that to their attention.

Mr. FORD. Do you feel it would be better if there were a provision to pin down the fact that there should be 3, for example, 1 representing each of the 3 services?

General MEDARIS. I think that would just carry some of these lovely arguments further.

Mr. FORD. Do you feel that the person from the Department of Defense should be a civilian or a military man?

General MEDARIS. I do not think it makes a whole lot of difference, Mr. Congressman. Probably in view of the fact that the Department of Defense is civilian directed and we subscribe to that kind of direction, it would perhaps be better if it were civilian.

The major problem is the question of the quality of the people that are put on this Board, not what kind of suits they wear or where they come from.

Mr. FORD. I gather, then, that you feel rather strongly it would perpetuate some of the alleged interservice rivalries if the Congress in such legislation wrote into the bill that there should be 3, 1 from each service, on such a board.

General MEDARIS. Congress would almost be forced to make it 4, then, 1 from each service and 1 from the Department of Defense.

Mr. FORD. It might even be five with the Marine Corps.

Mr. BROOKS. With the Coast Guard it would make it six.

General MEDARIS. I am afraid this is a matter for the determination of the Congress.

The only thing I can say is that I feel again the quality of the people put on the Board is the real matter and there must be a means for introducing into the Board's discussions the knowledge of the current planning and the current requirements of the Department of Defense agencies and the departments of the military services with respect to their need for their own weapons and the impingement of that need on the resources that could possibly be used by this agency.

Mr. FORD. Earlier you indicated that you had called on NACA for certain work in their facilities and with their personnel.

As you visualize this new agency, the process might well be reversed, they would be calling on you rather than vice versa?

General MEDARIS. I would presume so.

Mr. FORD. Do you think that reversal of procedure would have any adverse impact on your working relationships?

General MEDARIS. I have to reduce these things to a rather simple premise, myself.

We have resources. We have capability. We want to use them in the national interest. To do so we require intelligent direction and the provision of funds. Where that direction and those funds come from is not important, provided it is intelligent direction, provided we can get decisions, provided our resources are utilized in the national interest.

Mr. FORD. So far, your relationships with NACA have been satisfactory?

General MEDARIS. They have always been satisfactory. Yes, sir.

Mr. FORD. That is all, Mr. Chairman.

The CHAIRMAN. General, Secretary Brucker reorganized the four major research and development units under your command. Will you put in the record, without my asking you the questions, just what the effect of it was, what is under your command at Huntsville and the missile testing center, Redstone, and so forth; also, what authority you have for straight action rather than going through a number of difficulties which have existed heretofore, which are unnecessary to go back on because we have to look to the present and the future, at least as far as I am concerned.

Do you have in mind what I want?

General MEDARIS. Yes, sir; I think I know what you want, and we will put that in the record.

(The material furnished was classified.)

The CHAIRMAN. Mr. Fulton.

Mr. FULTON. General, we are glad to have you here. Your testimony brings up the point of how we should legislate in order to keep——

The CHAIRMAN. Will you pardon me a minute. I see General Gavin is here.

General, would it be agreeable for you to appear at 2:30. We will have to recess because the House will be in session. Will that be agreeable to you, General?

General GAVIN. I certainly can, although I have an appointment tonight I must make and fly back South.

The CHAIRMAN. Let us make it 2 o'clock. Will that be agreeable to you?

General GAVIN. That is fine. I will be right here, sir.

The CHAIRMAN. Now, you gentlemen continue with General Medaris.

Mr. FULTON. The question comes up how Congress can frame legislation so that we can keep the advantage of the agencies that are already in being and likewise add further facilities and maybe policy direction without limitation.

So that in the act on page 2, the bill that has been introduced by Congressman McCormack, and some of the rest of us. The one we are referring to is H. R. 11881. On line 4, it states:

> That the Congress further declares that such activities should be directed by a civilian agency exercising control over aeronautical and space research sponsored by the United States, except insofar as such activities may be peculiar to, or primarily associated with, weapons systems or military operations, in which case the agency may act in cooperation with, or on behalf of, the Department of Defense.

Does that language, in its present framing of the words, restrict your operations or can you live with that language?

General MEDARIS. I am afraid, Mr. Congressman, it may be a question of the interpretation of the language rather than the language itself.

If the language is interpreted to hold a very tight rein on the military departments and the Department of Defense, with respect to basic and applied research projects, which may yield things beneficial to the military, it can be a detriment, if it is very tightly and restrictively interpreted.

As I mentioned before, one of our objectives and one of our hopes has been to get more latitude in the area of working toward the

translation, toward the penetration of frontiers, that we believe may have military significance.

And the second step of translating new knowledge into practical form in terms other than a final weapons system, in terms of those things which will contribute a final weapons system, I would hate to see that go backward.

It has been bad enough and we hope it will be better. So it will rest entirely on how restrictively the language is interpreted.

Mr. FULTON. In your statement on page 2, you said:

> The United States Ordnance Missile Command is without any limitations as to whether either the end items produced or the knowledge gained are to be devoted to sole use of one military service.

I think that is a good statement, but the question that I am bringing up now is. Should you be limited in your particular programing simply to activities that may be peculiar to or primarily associated with weapons systems, or military operations?

My feeling is that you should not, that you should have a broader field of basic research which might be the foundation stones for later systems.

General MEDARIS. I agree, sir, I feel that we should have, that the services should have a broader mission in the area of missile research.

Mr. FULTON. As a matter of fact, do you agree with Dr. von Braun that the fact that the budgeting requirements have almost forced you to look for a military end item result has caused an impeding of the development programs?

General MEDARIS. I feel so, and I have so expressed it in the past.

Our weapons programs actually would be more efficient and would be cheaper if we could get further into the area of the application of the product of research before we committed ourselves to a definite weapons system.

In the long run, I do not think we would spend any more money. There is a gap period during which there would be some duplication or some additional expenditure to pick up this intermediate area of applied research.

But once we got by that we would spend no more money and perhaps less, because we would have a clear knowledge of what we wanted in the weapons system, before we committed ourselves to final design.

Mr. FULTON. On page 16 of the McCormack bill, there is a Section 8, Transfer of Related Functions. This section refers, of course, to the transfer of functions to the new space agency.

It states that for a period of 3 years after the effective date of the proposed act, the space agency, with the concurrence of the head of the department, or the agency concerned, and with the approval of the President, may transfer to itself any functions, including powers, duties, activities, facilities, and parts of functions of such department or agency, or of any officer or organizational entity thereof which relate primarily to the functions of the space agency.

Would you retain in the proposed legislation, then, for 3 years, the requirement that a particular agency, such as yours, should consent to the transfer of the facilities or functions to the new space agency?

General MEDARIS. That is one solution, but it, of course, implies that the people who would be operating the new space agency might not be trusted to examine with clarity and objectivity the conse-

quences of dividing and splitting organized and functioning groups.

Mr. FULTON. If I could refer your attention to the fact, it says that for a period of 3 years after the effective date of the act, this consent is required. Does that in any way alter your opinion?

That is a transitional period, it would seem to me during which it would require the consent of the agency concerned before facilities, functions, or personnel were transferred to the space agency without its consent.

General MEDARIS. Well, as to that 3 years—maybe I should not say this—but if for that 3 years I have the present Secretary of the Army, I have no fear.

Mr. FULTON. Fine. On page 8 of the proposed legislation here is something that might strike closer to your financial policy and your pocket in your type of agency.

At the bottom of the page on line 20, it says:

> In addition to authority to use provided by this subsection and, notwithstanding any other provision of law, any governmental agency or component thereof is authorized to transfer to the agency, without reimbursement, supplies, equipment, aircraft, missiles, space vehicles, and related parts other than administrative supplies or equipment.

I would like to ask one question on that: Would it not hurt your military program development to have to take steps without reimbursement to provide materials for the so-called new and expanded space program?

Should we not say as a matter of equity that an agency such as yours, that has been operating these programs so far, should be fully reimbursed in its budget for the current value of any facilities or items that are transferred to the new space agency?

Is that not just robbing Peter to pay Paul?

General MEDARIS. Again it is a question of how it is handled, Mr. Congressman. They are permissive in nature, they are not mandatory apparently from the language and if they are carefully evaluated and if that authority is resorted to only in those cases where there may be some facilities—I don't know of any in my complex—that could be transferred without a loss to the military program, in other words, they are surplus to the military and are required only for the kind of thing the agency is going to do and which could not be done by the group which presently has the facilities and if the transfer of missiles and hardware were confined to those which inevitably turn up in very small quantities as a byproduct of a development program and therefore would not impede the military program by making them available without reimbursement, then it is a sound and appropriate way to do it.

On the other hand, if it becomes the basis for straight out piracy, why, we are in trouble. It is just that simple.

Without some such authority, of course, we would be in difficulty even if we have an extra test missile left over from a test program that has come to a more rapid conclusion than it was expected to and we wanted to use that on behalf of the space agency to do something for them we could not do so without being paid back, without some such provision.

So again it comes back to the intelligence with which it is administered.

Mr. FULTON. As to the continuation of ARPA, I would like to point out to you that in the President's message of April 1, he said:

> I am requesting the Department of Defense and the National Advisory Committee for Aeronautics to review pertinent programs of the Department and to recommend to me those which should be placed under the direction of the new agency. It is contemplated that the Department of Defense will continue to be responsible for space activities peculiar to or primarily associated with military weapons systems and military operations. Responsibility for other programs is to be assumed by the new agency.

So that, obviously, it would seem that ARPA is to be continued for military-type programs.

General MEDARIS. I don't know. I frankly don't know. I don't have any idea.

Mr. FULTON. You have brought up a question of whether the whole space program should be centralized under one agency. When we have the military policy integrated under an arrangement where one of the members of the new NASA is a military man, it would seem to me that the overall space policy would be set by NASA.

Now, that same question came up in 1928 in Russia and Tupelov recommended to Stalin that the research and development in Russia be decentralized.

If we in the United States adopt this new NASA agency, are we not going opposite Russia, because at present Russia now has 775 technical institutes operating on research and development?

The question is: Should we keep you people, that have been operating on your programs, decentralized, or should we in Congress prepare legislation which will pretty much centralize policy, both civilian and military, under an overall national space agency?

General MEDARIS. There is quite a difference between a centralization of policy and a centralization of activities. Centralization of policy appears to be rather essential to decisiveness, to getting of decisions as they are required.

I would certainly not be in favor of any series of actions which resulted in centralizing operations in the research and space fields, or any other fields, which purported to bring all of those into one entity of operation.

Mr. FULTON. But you would not object to an overall civilian-dominated space agency which sets a national space exploration operation policy, would you?

General MEDARIS. I could not validly do so because they finally are also, I would presume, subject to the national policy decisions stemming from the President and the National Security Council and would be expected to be responsive to the national policy.

As long as this is the case, the subordinate making of active policy is bound to be in coherent fashion related to the national policy.

Mr. FULTON. Do you favor the production of the million-pound-thrust engine as a crash program?

General MEDARIS. I am still convinced of the validity of my previous remarks that we have to have available a well-tested capability of a minimum of million pounds takeoff thrust, either by a combination of multiplex engines or by a single engine.

I lean rather to the combination rather than the single size, myself.

Mr. FULTON. How much will that kind of program cost?

General MEDARIS. Historically, the development of an engine up to the point of having fully tested prototypes and development-type

prototypes will cost somewhere in the vicinity of $75 million in that size, I would suspect.

Mr. FULTON. So to date there has been $500,000 authorized for the study of such a program and if it continues at the same rate it will take, on your figures, 150 years to develop such a program?

General MEDARIS. This, of course, would not be responsive. If it is to be done at all, it has to come out of that and get moving.

Mr. FULTON. That is what I am trying to come up with. So you think it is an urgent program and we should immediately have funds on a level that can get a good study going and get the procedure started?

General MEDARIS. I certainly do.

Mr. FULTON. So it would run in an area of fifteen to twenty-five million dollars that should be provided by Congress immediately?

General MEDARIS. Although this program has not been costed out, because we have no sponsored program of our own at the present time, but I would presume that the first year's operations, if this were to be done as a matter of urgency for any one engine, would have to run in the bracket from fifteen to twenty-five million dollars.

Mr. FULTON. As a matter of defense we will have this TLM-18, telemetry antenna developed, and we have only five of them in use now.

This is the United States Air Force automatic tracking telemetry antenna, used to track ballistic missiles, which is designated TLM-18.

Why do we not start on a very much expanded program of TLM-18 and scatter them around bases to see where the rockets are coming from before they come into the vicinity of the United States? Is that not an urgent requirement for the expansion of these telemetry antennas so that they may be used as pickets against rockets and ICBM's that might be launched?

General MEDARIS. This program is going forward under the antimissile missile program.

Mr. FULTON. Is it going forward quickly enough, or should we have a crash program on it?

General MEDARIS. I believe, Mr. Congressman, that the antimissile missile system should go forward at the absolutely optimum rate. I am opposed to the word "crash" program because there is a rate which will yield the fastest and best results which does not put you into the panic area.

Too many times when we talk about a so-called crash program we just mean to jump up and down faster and get a little more confused.

Mr. FULTON. But it should be done with urgency?

General MEDARIS. With maximum urgency and consistent with a sound program.

Mr. FULTON. Suppose you had the adequate funds and the command to go, full authorization, adequate facilities and equipment, and the choice of all available scientific and research personnel—that is an optimum situation—and were given the go-ahead, how soon could you take a target shot at the moon?

General MEDARIS. If I have all those things, I am going to do it pretty quick.

Mr. FULTON. How soon?

General MEDARIS. I am sorry, but you are asking me to violate a basic matter of my own personal feeling of what is right.

To focus the attention of the whole mass of people, press, and everything else, on a specific date for one of these occurrences, throws a handicap into the project itself that we can ill support.

I do not think it is wise and I have consistently declined to answer that question and I would like to have the privilege of declining it now.

Mr. FULTON. You see, on the X-15 the Air Force has said it will take them 2 to 3 years. Your own people have said that you can do a capsulized shot with a man in it quicker than that—about half as quick, in a year.

General MEDARIS. That is right.

Mr. FULTON. Why do you not make some comment, then, as to the time on this moon shot?

General MEDARIS. I will make only one. That is that my presently authorized satellite programs will be completed before April of next year.

Mr. FULTON. Thank you very much.

And the moon is one of them?

General MEDARIS. Yes, sir; this has been announced.

Mr. MCDONOUGH. General Medaris, I appreciate your appearance here today and I think you have done a very excellent job in informing the committee of the present status of our satellite missile and rocket program.

I agree with you on withholding any specific date on this so-called propaganda idea of shooting at the moon.

Mr. FULTON. Except for April 1959.

Mr. MCDONOUGH. In your opinion, do we have the basic research or the basic scientific data and the manpower in the United States to match Russia?

General MEDARIS. I have stated rather consistently, Mr. Congressman, that in my opinion, we do have as much and as good and as advanced information in all these fields as anyone else in the world has. I believe that intelligently directed, so that the efforts of the various teams of capable people in this country are consistently held into their most appropriate channel, so that each can be consistently working without interruptions or delays in a field appropriate to their knowledge and talent, that we do have what we need in the way of people, brains, capability, to match anybody.

Mr. MCDONOUGH. Do you mean industrial know-how in the civilian components as well as in the military components?

General MEDARIS. I am taking the across-the-board resources of the United States, the development teams, scientific teams, laboratories, university resources, the whole box together.

If all of the people that are available with sound knowledge, background capability, and experience in this field are properly utilized——

Mr. MCDONOUGH. Marshaled and coordinated, you mean?

General MEDARIS. Marshaled and coordinated. The major problem is to assure that each existing team and resource has a job to do that they can get on down the road with, are not concerned about what is going to happen next, as to whether they will be out of a job when this is done so they don't kind of timorously come to the tail end of it.

Mr. MCDONOUGH. Do you think the Aeronautics and Space Agency proposed in this legislation will help to coordinate that manpower in both the civilian component and military components?

General MEDARIS. It requires further coordination between that Agency and the Department of Defense to effect it.

Mr. McDONOUGH. In your opinion, is space more of a civilian advantage for exploration, or a military advantage?

General MEDARIS. I think it is a civilian advantage and a military necessity. I do not think it would be possible to put an outright priority on either direction.

Mr. McDONOUGH. Of course, it is difficult to anticipate what it will develop into, but at the present time should the emphasis be on military or civilian exploration?

General MEDARIS. At the present time the emphasis is properly on space science. You can interpret this as civilian or any way you like, but the present emphasis must be in the direction of finding out what we possibly can about the environment and about the means for handling that environment.

Mr. McDONOUGH. On that particular subject, do you think we have, at the present time, as much on such matters as the Soviet Union?

General MEDARIS. I do.

Mr. McDONOUGH. And that we can continue to acquire knowledge just as rapidly as they can on that subject?

General MEDARIS. I see no reason why we should not.

Mr. McDONOUGH. Now, if we, in the process of developing this space exploration, come to some sort of international understanding or treaty with the Soviet Union and the other nations of the world that space shall be used for peaceful purposes, what position will that put your military development and research into?

General MEDARIS. Of course, first of all, this is like any other approach to the question of disarmament because it is disarmament before the fact rather than after the fact, but it is the same thing.

First of all, as a military man and therefore charged with some sense of responsibility for the Nation's defense, I have to urge that any such agreement should be adequately backed up by proper and complete guaranties against its violation.

Assuming that such were present, this would still not diminish, in my opinion, the advisability of pushing further into the knowledge of space and how to handle it, to the ability to use it to man's ends.

Mr. McDONOUGH. By the military?

General MEDARIS. I believe that the military has an adequate background of being able and willing to cooperate with and benefit the peaceful activities of the country as well as the military.

May I draw a parallel, that in the winning of the West, the military had a very significant part.

Mr. McDONOUGH. You mean to fight off the Indians and let the white man move in?

General MEDARIS. This was only part of it. Some of the transportation that went into the West was based on military necessity. Yet the end result of it was the opening of a tremendous new frontier and land empire to the United States.

Mr. McDONOUGH. Do you look upon space now, since Russia did not challenge us and we did not challenge them on releasing satellites into this common highway in the universe, do you look upon space now as in the same position as the freedom of the seas that is enjoyed by all nations?

General MEDARIS. I think this is a question that had better go to some lawyers. It gets a little bit involved for me, sir.

Mr. McDONOUGH. I realize that, I am not asking for a legal opinion, but I am pointing to the fact that we are not challenged on it, that it is open territory.

General MEDARIS. This might be true or it might be there is no challenge raised because there is no effective means of enforcing the challenge.

Mr. McDONOUGH. For instance, we do have freedom of the seas now. We have to maintain that freedom by resisting any nation that may challenge our position on the seas.

General MEDARIS. That is right.

Mr. McDONOUGH. Therefore, the military comes into position.

Do you think our military position in space, regardless of an international understanding or agreement, will still require military implementation and manpower to resist any nation that may challenge our position there?

General MEDARIS. I think that no international position can ever historically be considered firm unless the capability exists of supporting and enforcing your position by military means.

Mr. McDONOUGH. Now, insofar as the agency is concerned, do you think that we ought to make a straight line command on this situation? I am not talking now about reorganization of the Defense Department, but on space development. Ought it to be through a single line of coordination rather than two agencies? That is, aeronautics and astronautics?

General MEDARIS. As there is a very definite alliance between missiles and space operations, there is also a very definite alliance between aeronautics and astronautics.

There is an interreliance and interrelationship. Certainly aeronautics and astronautics should not be marked out as separate areas. If there is to be a civilian agency controlling the scientific effort of the United States in the space area, there must remain some responsibility within the Department of Defense for its military requirements.

It would be highly impractical and unwise in my own personal opinion to concentrate all outside the Defense Department.

Mr. McDONOUGH. That is all, Mr. Chairman.

Mr. BROOKS (presiding). Do you have a question you want to ask?

Mr. FULTON. With the new Russian rocket they have just announced, called Molnitsa, they have put a dog into space 132 miles. Why is it going to take us in the United States so long to put a manned vehicle or rocket, such as Dr. von Braun spoke about into space 150 miles?

Why should it take us a year, when the Russians just this week announced they have a dog they have sent up and returned very happily?

General MEDARIS. I could perhaps answer your question if I knew when they started on this project. I am quite sure they did not start 60 days ago on that project.

I would have to go back and quote what I think is one of the more outstanding remarks of World War II when General Knudsen, in attempting to demonstrate to the Congress why tanks could not be had flowing out a day after the contract was let, finally in exasperation

said, "We have the best obstetricians and the best hospitals in the country, but, by gosh, it still takes 9 months."

Mr. BROOKS. General, you say that everything is going fine under your command and you are satisfied with the progress you have made. Now, I have heard statements made that things are not so satisfactory. How have you ironed out all your differences and your problems so that there is nothing wrong?

General MEDARIS. I believe that within my command we have no problems that we cannot solve. If we ever have no problems, we will dissolve the command.

Mr. BROOKS. Will you say that again?

General MEDARIS. I said within my command we have no problems we cannot solve—within the command. Whenever the command has no problems we should dissolve the command.

Mr. BROOKS. You are satisfied, though, with the progress you are making in resolving your problems and you have no differences there that are brought to your attention and are subject to conclusions?

General MEDARIS. I am afraid I don't understand. Are you dealing with matters within the command among the agencies?

Mr. BROOKS. Yes; and the lack of progress. We have read different criticisms about lack of progress in the past. I, myself, think you are a very able officer and the country is fortunate to have you. But, aside from that, I have read of some criticism and the committee will probably get some criticisms, too.

General MEDARIS. I don't think we will ever have the time when somebody will not have the feeling that they can sharpshoot about something that we are doing. I will never say that I am satisfied. I am never quite satisfied.

We are making sound progress and continue on schedule in the more important areas that are assigned to my charge. We have some points that I am not satisfied with, if I take all the programs that are under command jurisdiction.

We go about curing those. We have some things that we would like assigned to us that we have not had assigned to us.

Mr. BROOKS. What is that?

General MEDARIS. We hope to have those assigned to us as fast as they can be resolved. These are in the areas I have discussed, of applied research and a few additional——

Mr. BROOKS. Who is holding that up?

General MEDARIS. I would not say it is being held up, Mr. Congressman.

Mr. BROOKS. Whose failure is it to let it go through?

General MEDARIS. There is no failure. These things must have their consideration.

There are probably, as you were told yesterday, undoubtedly thousands of schemes that have been presented in the light of recent developments. We try to present ours in a sound——

Mr. BROOKS. All we are asking of you is a frank statement. Specifically, what do you think of some of the references by General Gavin, for instance?

General MEDARIS. To our programs?

Mr. BROOKS. Yes

General MEDARIS. I do not particularly know what references you might have. I think it is the general position of informed military

personnel that the translation of new concepts into sufficient force in being in the Army is not what we would like to have it, where we believe it should be.

This applies across the board, in the missile field as well as others.

If that is what you refer to, why, none of us are satisfied.

Mr. BROOKS. Of course, I know you were not satisfied when the order came down, on September 20, 1956, to hold up the development of the Redstone-Jupiter rocket. I assume you protested then?

General MEDARIS. Very much so.

Mr. BROOKS. But that has thrown us back about how far in the development of the program?

General MEDARIS. I do not think that really wound up holding us back at all. I went through this era sometime back and by just keeping our head down and trying to make up for delays by extraordinary efforts and insistent reclamas, we managed to stave off any delay until the decision was finally made to field both the Jupiter and the Redstone.

Mr. BROOKS. In the testimony, it was mentioned that we were delayed a year and we would have had the satellite up a year before Russia.

General MEDARIS. If you were referring to the satellite, that is a different matter. I was referring to the Jupiter program and weapon program.

Mr. BROOKS. This is the satellite.

General MEDARIS. It is a Redstone booster and does not depend on Jupiter hardware.

Mr. BROOKS. The basic hardware is Redstone and the Jupiter is attached to it.

General MEDARIS. No, sir.

Mr. BROOKS. Section 2 or 3?

General MEDARIS. No, sir; there is no part of it associated with the Jupiter weapon system. The reason it was designated Jupiter C is because it was a test vehicle in the Jupiter program, a special test vehicle in the Jupiter program for reentry test.

None of the hardware in the Jupiter C, which was the satellite carrier, is the same as hardware in the Jupiter missile.

Mr. BROOKS. Would you call Explorer No. 2 a success or a failure?

General MEDARIS. Explorer No. 2 was a failure. It did not get into orbit and that was the purpose of the exercise.

Mr. BROOKS I am asking you how far it did get. I assume it was pretty close to orbit

General MEDARIS. Well, it lacked the fourth stage, but the difference in velocity between the third and fourth stage is tremendous because you are already in the atmosphere, you are a vacuum trajectory, you are in a light article, you get a tremendous acceleration in velocity in the last stage.

Mr. BROOKS. The trouble was with the last stage?

General MEDARIS. That is right. The last stage did not ignite.

Mr. BROOKS. Was that Redstone?

General MEDARIS. No, sir. These were special clusters of solid rockets that were designed for the Jupiter-C vehicle. That was the first ignition failure we had

Mr. FULTON. Before you leave your question, you have asked him the question: What project would you like to have assigned to you specifically?

You have been asked that question and there has been no answer to it.

Mr. BROOKS. I asked him the question. I did not push him because I know the general is fair and is anxious to give us all the information available.

General MEDARIS. I feel somewhat reluctant to answer that question because we are presenting the projects that we believe we can do.

We are presenting them as thoroughly as we know how. We have not been turned down on any of them. There has not yet been time to evaluate the ones to which I refer, to evaluate them properly.

Mr. FULTON. You see, we have confidence in your organization and since this committee, through its members, seems to indicate they want you to go ahead much faster and to have every facility, we would like to have you tell us how we can accommodate you.

I do not want to be in a position where you would be saying this is as fast as the Army Ordnance can march and that is as fast as it is going.

General MEDARIS. I am not saying that. We are asking for approval of an additional space science program with some military application, extending further ahead than that one we now have, so that we can look further into the future.

Mr. FULTON. Could you outline that last statement in the record at this point, with the chairman's permission, at a later time?

Mr. BROOKS. If you could elaborate on that in the record, it will be fine.

General MEDARIS. I believe, sir, it should be submitted under classified cover.

(The material furnished is classified.)

Mr. BROOKS. I recognize counsel, Mr. Feldman.

Mr. FELDMAN. General, before this you said you had some experience with the NACA and that that experience was satisfactory.

I wonder if you can tell us whether you start by submitting a project directly to NACA, to its Director, or go to a committee?

General MEDARIS. As I mentioned, the projects that we have asked NACA to do for us have been quite minor and involved the use of some of their specialized facilities.

In those cases we were able to make the arrangements directly with the laboratory, or the agency of NACA, concerned. We don't have to go to headquarters for those.

Mr. FELDMAN. Are you acquainted with the fact that the NACA has a large number of committees and subcommittees?

General MEDARIS. I am.

Mr. FELDMAN. And that many projects go to these various committees and stay there a long time?

General MEDARIS. I have not in my work been subject to the area in which these projects are effective and, therefore, it has not happened to me and I just don't know about it.

This is the point——

Mr. FELDMAN. I wondered whether you had any knowledge on that point?

General MEDARIS. No, I do not.

Mr. FELDMAN. Now, what is your opinion, General, on the merits of competitive programs within the Military Establishment?

General MEDARIS. I think they must be gone at quite selectively. There are many places where competitive programs are not warranted, but there are other places where I believe they are warranted. And in two degrees:

There are places where a full competitive program, that is two competitive systems, may be warranted.

There are more places where competitive parts systems are justified.

For my own part, the type of analysis that I apply to this kind of area has to do with two things:

First of all, it has to do with the degree of certainty with respect to actual conclusion on one dependable line of approach.

Secondly, with the degree of urgency and the importance that could be attached to a partial failure or considerable delay.

These are the things that must be assessed. If you are in an area where there is valid doubt as to the success of a single line of approach, where there is not absolute assurance, and you have a mandatory time scale that will prejudice the security of the country if it is not met, then definitely the competitive approach is justified.

Mr. FELDMAN. Do you feel that the satellite program in support of the IGY should be divorced from our military program?

General MEDARIS. If it had been wholly divorced we would not have two Explorers up there now. In other words, it was supported by military hardware, this is the point.

Mr. FELDMAN. That was precisely the point I was trying to bring out.

General MEDARIS. I think I can state my feeling again in very concise terms on this. If you try to place the entire space exploration program independent of military support, independent from military programs, you are going to pay an awfully big bill. It only makes sense that those elements of military programs which result in the development of a type of hardware that can contribute to space exploration should be used for that purpose.

And you should not have to pay development costs twice just because this one had a military tag on it. You have paid that already, let us use it.

Of course, we kind of like to use the hardware that we buy. We do not like to give them to someone else to use them.

Mr. FELDMAN. In that connection, scientist Lloyd Berkner is quoted as having said:

> Pure scientific problems involved are complex and their solution can be best achieved under civil auspices closely related to the academic atmosphere because they transcend the normal limits of military technology.

What is your opinion of this statement?

General MEDARIS. I do not think he realizes the limits of our technology. I think he is downgrading us a little bit.

Mr. FELDMAN. Would you say that the horizons are about the same as they are in space?

General MEDARIS. I certainly think so.

Mr. FELDMAN. What are the scientific values of an unmanned space program?

General MEDARIS. First of all, even if we are not going to use space as a new frontier of travel and exploration, there are definite values to be applied to our own living conditions and our knowledge of the conditions that we must meet here on earth by having a much greater

knowledge of the whole characteristics of all those parts of the solar system which have an influence on the behavior of the earth.

To this end, or in that area, we can direct a specific application. We can say, for example, that if we can find out the exact pattern of the so-called space area around the earth and out at least as far as the earth's own satellite, the moon, that we will be able to better interpret and know what the longer range trends of man's environments are going to be.

We will know more about the whole problem of the influence of the race and energies that exist in outer space.

It is not really a vacuum; there is a lot of stuff out there, it is not just air. It all has an influence on our atmosphere and our environment.

The true magnetic shape of the earth has a very definite influence on our communications problems and communications reliability. This can only be determined by space experiments.

There are certain functions made, but so far we have found that where we have explored the deductions, shall we say, have had to be refined at the very least.

Beyond that, however, we come to the point that if man is not to stand still and standing still means going backward, then for any knowledge we can acquire he should acquire, and this is for its own sake, because we are not smart enough to see where we are going with all of these things.

History is full of examples where things were stumbled on as basic principles and the man who did it had no more idea what it meant than you can imagine even as late as 50 years afterward somebody came along and found that that was a basic requirement to something that was needed at that time.

But it only came about because somebody was curious. So I feel that wherever there is the possibility of acquiring knowledge, it should be accepted as a challenge to a man to find go out.

Mr. FELDMAN. I think a very apt example would be what Goddard had to go through when he developed the missile.

General MEDARIS. That is right.

Mr. FELDMAN. Now, can you tell us the achievements of the United States Army Ordnance Missile Command? I mean specifically. You can review some of the important ones, in any event.

General MEDARIS. The organizations which constitute the United States Army Ordnance Missile Command have historically, going back to the years even before World War II, been responsible for either the direct development or the direction of development and conversion to weapons systems and fielding of all of the missile systems that the Army now uses and those which are coming on.

I think the series of names is well known to everybody. They range all the way from short-range tactical missiles through the Corporal and Redstone into the longer range field.

They also have been responsible for a great deal of fundamental investigation and development in the area of solid propellents.

The Jet Propulsion Laboratory and the organizations at Redstone under the cognizance of the command, inhouse laboratory at Redstone Arsenal, I should say, have contributed a major share of the basic advances in solid propellents, in case bonded propellents and in the composite propellent field.

They were responsible for the earliest successful JATO, jet-assisted takeoff, both also for the Air Force later taken over and developed by others to a greater extent.

The primary investigations and results that have been achieved in the air defense system through the whole generation of Nikes have been under the sponsorship, direction, and guidance of the then Redstone Arsenal, now the Army Rocket and Guided Missile Agency.

The programs have been conducted, some by industry and some inhouse, but always against the background of existing technical knowledge, and a fine group of highly qualified people to guide and influence and make these programs that they might achieve the most useful ends.

I could actually put in pages if we were to go into the scientific area, of the new things that have come out.

Mr. FELDMAN. Could you do that for the record when you edit the record?

(The material furnished is classified.)

General MEDARIS. We can certainly give you a representative sample of these things. One that I would particularly like to mention is that the first successful missile inertial guidance system in the country was flown as the complete result of the development work of Dr. von Braun's group and was flown on board the Redstone 5 years ago.

This is not thoroughly understood by everybody.

Mr. FELDMAN. I think it is a very imposing list of achievements.

I think Dr. von Braun, the other day, suggested using missiles for troop movement. That would be pretty costly. Would that be justified, or would it be feasible?

General MEDARIS. I think this is maybe a misconception. If we take the figures well known to the Congress with respect to the cost of acquiring, maintaining airplanes, and training aircrews and if we add to that the attrition in wartime that occurs when you attempt a passage over unfriendly territory, I think it is a demonstrable fact that you can deliver a pound of cargo any time in the combat zone cheaper by missile than you can by combat aircraft, even though you throw away the bulk of your missile.

And in this question of troop transport, I do not visualize at the moment the volume requirement over long distances that I think Dr. von Braun visualized, but there is no question but what a means has to be developed by which Army special forces can be put where they are wanted and the special forces are usually groups of 3 or 4 people and this is a game we have to know how to play, and when the time comes that you cannot get them in there by airplanes, that the defense system effectively precludes this without a very high degree of risk and high percentage of loss, there still has to be some way of getting this small group in there with what you need and get it in behind the areas controlled by others.

The only solution to that problem that I see is missiles.

Mr. FELDMAN. You conceive, in other words, almost a complete defense against invading aircraft?

General MEDARIS. I think this is quite true. I think this is in the foreseeable future and I believe everybody recognizes it, certainly against that type of aircraft that can be reliably used for delivery of personnel and cargo.

To what extent it may be possible to develop aircraft-type vehicles that are clear up to the boundary line between the atmosphere and space, and who, by their tremendous speed, can protect themselves, this does not enter into the other problem, because with those you cannot deliver accurately these small quantities of cargo and small numbers of people that are required at specific places in any fast-moving and wide-ranging patterns of warfare.

Mr. FELDMAN. Also, you could work on both developments at the same time and possibly come up with a solution the other way as well as this way.

We know also the fact that this type of aircraft we are talking about would have a rocket thrust for the most part. Is that right?

General MEDARIS. That is true.

Mr. FELDMAN. It would be a kind of hybrid rocket.

General MEDARIS. In a sense, yes.

Mr. BROOKS. Of course, manned aircraft may reach astronomical speeds, too.

General MEDARIS. That is quite true.

The kind of mission I am talking about depends on lower and slower aircraft for its accomplishment. It just cannot be performed by tremendously high speed aircraft at extreme altitudes.

Mr. FELDMAN. What do you consider the most logical and practical sequence of essential steps or phases in a coordinated space program?

General MEDARIS. The Army Ballistic Missile Agency submitted some time ago their suggestions for a national integrated missile and space vehicle development program. That is in the hands of the people who are concerned with this. It is a rather detailed approach to the whole problem.

Mr. BROOKS. Could you put that in the record, General?

General MEDARIS. It is a classified document. I will be glad to have it transferred to the committee, as such. It is a classified document because this is an integrated space and weapon program.

Mr. BROOKS. You can hand it to counsel, then.

General MEDARIS. We will transfer it to counsel as a classified document.

Mr. FULTON. Is there any part, Mr. Chairman, that can be declassified?

General MEDARIS. From it there can be derived a perfect series of steps that appear to us to be logical in the movement in the space area.

Mr. FULTON. Could we have that kind of statement produced by the General for the record at this point?

General MEDARIS. We will do so.

Mr. FULTON. If there is no objection.

Mr. BROOKS. If there is no objection, it will be inserted in the record at this point.

(The material referred to is classified by the Department of the Army.)

Mr. BROOKS. It is 12:30. We are going to meet again at 2 o'clock.

Mr. FELDMAN. Supposing I submit the questions for the record, General?

General MEDARIS. We will be glad to submit the answers for the record.

(The material referred to above follows:)

Answers to Questions

Question 1. In regard to our space program, what is your opinion on the merits of a single military responsible agency versus a single civilian responsible agency?

Answer. I believe that the management of military and scientific space programs can be most effectively accomplished by placing the managerial responsibility for both programs in the hands of a single individual, preferably within the Department of Defense. I do not believe that such overall control should be a military operation, controlled and directed by a military man. It can, however, work either within or outside the Department of Defense.

Question 2. Do you feel that the separation of military and civilian scientific phases within the same agency is practicable?

Answer. It is my opinion that the military and civilian phases of space research and development cannot be practically separated within the same agency because the two phases are inextricably related. The ballistic missile, after all, is still the basic building block of any space program.

Question 3. What is your opinion of the merits of competitive programs within the Military Establishment?

Answer. I believe that the practice of conducting competitive programs within the Military Establishment is a practical means of stimulating development and at the same time assuring the Nation that all of its eggs are not in one basket.

Question 4. Do you feel that our satellite program in support of the IGY should be divorced from our military effort?

Answer. I believe that the decision to divorce the IGY satellite program from military effort was not the best one, since this work is directly related to the ultimate development of military satellites; however, Monday morning quaterbacking in this business requires nothing more than a willingness to talk. I wish to affirm my opinion that the people who made this decision were doing their best to make that decision a good one.

Question 5. What has been achieved by the organization of the United States Army Ordnance Missile Command?

Answer. The United States Army Ordnance Missile Command was established to provide centralized direction and control of all Army missile development resources and activities. The scope of the command's responsibilities includes direction and control of the entire sequence of weapons-system development, from feasibility study to field support of the tactical system when it has been deployed. This centralized-systems management, located in one place, assures continuing cognizance and coordination of all Army missile-development activity, and permits the immediate accomplishment of any action required to make an assigned weapons system usable in the field.

Certain elements of the Army Ballistic Missile Agency which provided across-the-board Army cognizance of all activity related to missile development were made available to all missile systems assigned to the Ordnance Corps. Several elements of the new command headquarters maintain direct and continuing contact with other technical services of the Army, and with other responsible Army elements. In this manner, the command determines current requirements and military characteristics, and in special cases provides direct support for activation and training of new troops to fit the development of new systems. Other command elements provide the means to efficiently operate the resources under the command's direction, assuring optimum development of new systems, continuing support of missile systems in the field and the proper phasing-out of systems and materiel as they become obsolete.

The proper definition of a weapons system must include not only personnel, materiel, supporting logistics, and technical resources, but must also include the integration of the system and its using personnel with the total tactical system that is required to make a weapon an effective part of the user's arsenal.

Complete systems management envisages a degree of coordination and, where authority does not exist for coordination, envisages participation in establishing requirements, and subsequent system examination to bring any system deficiencies to the attention of the responsible headquarters.

The organization of the command headquarters is streamlined and compact, and can assure fast and effective decisions as they are required. This capacity for immediate action in high priority programs is aided by the delegation of special powers to the commanding general of the command, which gives him direct access to the Army Chief of Staff. Additionally, all Army resources which related to the high-priority missions of the command have been made responsive to the needs of the command's programs.

Question 6. What are the scientific values of an unmanned and manned space program?

Answer. I believe that the scientific values of an unmanned and manned space program are virtually innumerable, encompassing revolutionary contributions to the fields of communications, meterology, geodetics, etc. I also believe it foolish to wait for an assessment of expected gains before beginning preliminary space research.

Question 7. Some feel that space exploration should be a pure civilian scientific venture over which the military should have no control. What is your opinion?

Answer. The point is not whether space exploration should or should not be a pure civilian venture; the point is that historically no nation has ever laid claim to anything and held it without military support.

Question 8. Why is the Army concerned with space exploration? What is the Army's need with relation to space travel?

Answer. The Army is immediately concerned with space exploration as it relates to communications, weather intelligence, troop and cargo transport, etc Additionally, as man extends his activity away from Earth he will inevitably carry with him the same basic needs which he has on Earth, protection included. Aside from those space exploration activities which relate directly to its missions, the Army is interested in space research because it has, now, the ability to make a singular contribution to the mastery of space, without regard to whether this contribution is in support of its own missions or not.

Question 9. It would appear that using missiles for troop movement and support would be much too expensive. How can you reconcile the cost factor?

Answer. I believe it is a demonstrable fact that a pound of cargo can be delivered to a combat zone more cheaply by missile than by combat aircraft. This opinion is well reasoned if one considers the figures concerning the cost of acquiring and maintaining aircraft, training aircrews, and adds to these costs that of the attrition of aircraft during attempted passage over unfriendly territory during time of war.

Question 10. What do you consider the most logical and practical sequence of essential steps or phases in a coordinated space program?

Answer. I consider the most logical and practical sequence of steps in a coordinated space program to be the following:

1. A moon probe;
2. The launching of a manned satellite;
3. A moon landing and return; and
4. A planetary probe.

Question 11. Which of these might be effectively pursued concurrently by different activities?

Answer. Again, I wish to point out the advisability of assigning the accomplishment of these steps on a competitive basis whenever possible, to make certain that their sequence is orderly and timely and that the failure of a single project does not spell failure for the entire program.

Question 12. What are the separate projects that should be undertaken in a national program?

Answer. Some of the separate projects which, in my opinion, should be undertaken immediately include: (1) Development of an engine of much greater thrust; (2) development of various types of satellites, i. e., communications, visual surveillance, manned satellites, troop carriers, supply vehicles, satellite interceptor systems, etc.

Question 13. Has the Army ever offered for consideration any kind of unified space program?

Answer. The Army Ballistic Missile Agency has submitted to the Chief of Research and Development, Department of the Army, a proposal entitled "A National Integrated Missile and Space Vehicle Development Program." On February 19, 1958, the Army recommended that the Department of Defense implement the provisions of this proposal.

Question 14. What space capabilities does the Army Ordnance Missile Command now possess, both scientific and military?

Answer. The United States Army Ordnance Missile Command has within its framework the capacity for accomplishing a significant portion of this Nation's ballistic weapons and space vehicle development. The Development Operations Division of the Army Ballistic Missile Agency, under the direction of Dr. von Braun, is staffed around a nucleus of well-known authorities in the field of astronautics and missile development. Certainly the capabilities of this unique concentration of experts, coupled with the capabilities of the Jet Propulsion

Laboratory, must be utilized if this Nation is to accomplish the true integration of a national space program. The United States Army Ordnance Missile Command will continue to make proposals placing its available developmental capabilities in support of any agency which has need of them.

Question 15. What capabilities can it develop for the future?

Answer. The recent organization of the United States Army Ordnance Missile Command assures sustained, concentrated surveillance of research, development and production in the field of missiles and in the research and development of hardware for space exploration. The inhouse developmental production capability of ABMA, plus that of Jet Propulsion Laboratory, plus the contracted capabilities of the many private industries supporting command programs, are being constantly assessed to maintain a continuing knowledge of the command's ability to absorb new programs. As technology matures, pointing out weakness in some programs and strength in others, the command organization will permit a shift of emphasis to any developmental area. In this manner, the activities of each command agency can be quickly fitted to the demands of the future.

Question 16. What responsibilities have been placed on the Army with regard to satellite and space programs?

Answer. With the firing of Jupiter C missile 29 on January 31, 1958, the United States Army launched the first United States satellite, Explorer I, into orbit. Explorer II, fired with Jupiter C missile 24 on March 5, failed to orbit because the missile's fourth stage rocket did not ignite. The Army's third satellite firing was attempted 21 days later, and was completely successful in placing Explorer III into orbit. Early indications that Explorer III's orbit was not a healthy one proved incorrect. The satellite is fulfilling its missions. Incidentally the launching of Explorer III was scheduled immediately after Explorer II did not go into orbit; this is the finest proof of the Army's flexibility.

Currently assigned ARPA (Advanced Research Projects Agency) projects include:

(The rest of the answer to question 16 is classified.)

Question 17. How do you feel the Army can best contribute to satellite programs and space programs?

Answer. I believe that the Army can most effectively contribute to satellite and space programs by being allowed to pursue the programs which AOMC has recommended. A summary of the AOMC space program proposals will be submitted to this committee.

Question 18. What capability has the Army for putting a man into space and having him return safely?

Answer. AOMC has recently made a proposal entitled "Project Adam" which would launch a man into space. The launching would be accomplished within a Redstone missile. Because the reliability of Redstone is an accomplished fact, the launching could be carried out within 1 year.

Question 19. What breakthroughs, if any, are required to succeed in a coordinated national space program?

Answer. The major breakthrough which must be effected before any national space program can gain substantial impetus is the development of engines of much greater thrust. I am convinced that we must have a well-tested capability of a minimum of 1 million pounds thrust, either by a combination of multiplex engines or by a single engine.

Question 20. When can you expect to make the first moon contact?

(Answer to question 20 is classified.)

Question 21. When can you expect to establish the first manned satellite?

Answer. Before any valid estimate can be made of the time required to place a manned satellite in orbit, it is first necessary to know much more about man's behavior in space for a shorter period of time. For this reason I consider approval of Project Adam of paramount importance.

Question 22. What sort of schedule is necessary to overtake the Russians in a space program?

Answer. If the Russians are to be overtaken we must have an integrated missile and space vehicle development program, similar to that recommended to the Department of Defense by the Army.

Question 23. What specific hardware items must be developed immediately to achieve the goals of a national space program in the period 1960–70?

Answer. Again, engines of greater thrust.

Question 24. Why should the Army be concerned with large engine development?

Answer. I believe that the United States Army must make long-range plans for the transport of small combat teams by rocket. I also believe that cargo transport by rocket is economically feasible. To accomplish these things an engine of greater thrust is necessary.

Question 25. Is basic research—the ideas yet unborn—in need of greater financial support than is currently being given?

Answer. Basic research is always in need of greater financial support. In light of Russia's demonstrated lead in ballistic missiles, it is now mandatory that this need be met with adequate funding. It should be pointed out, however, that the dollar requirement for basic research is very small, applied research is the big money user.

Question 26. Is the Army receiving sufficient funds for applied research to attain the advances necessary for successful fulfillment of a national space mission?

Answer. It is my opinion that the Army is not receiving sufficient funding support of applied research. Research projects should be funded separately—funded as research and not tied to a missile program. Engine development, for example, should be funded as an entirely separate research and development program.

Mr. FULTON. This line of questioning as to the size of rockets for carrying brings up the question that has been worrying the public off and on and that is this: How about these space saucers? Are there such things? Do you give any account to them, or is that just a thing out of a book?

General MEDARIS. I have not been able to lay my hand on any evidence that I consider credible that such vehicles exist. I have, however, in this program that we are in these days, reached the point where I never say it is not so; I do not know.

Mr. FULTON. On the ionized rocket program at Los Alamos, it is estimated to take about 10 years before operation. Do you know any way that could be hurried up?

General MEDARIS. I doubt it. This is a very advanced propulsion system and our own calculations have indicated this is a reasonable period.

Mr. FULTON. There has been some contradictory testimony here as to the value of a research program on photon propulsion. Do you feel that is in the realm of practicality, that we should have a basic research program on photon propulsion?

General MEDARIS. I think a basic research program on it would be warranted. The purpose of the basic research program is to clarify this doubt. There are differences of opinion.

The only way you clarify them is to go far enough in the area of fundamental research to either come up with the conclusion that it is an approach that can be successfully followed through, or that it is not. So, definitely there should be a basic research program in that area in my opinion.

Mr. FULTON. Because of the tremendous weight factor, that is, on modern propellants, do you think, when we could by 1 pound of uranium take the place of a thousand tons of coal in energy or propel a rocket of tremendous size, there is enough being done in the study of our fuels and propellents for rockets and for space vehicles and missiles at the present time, or could that not be tremendously expanded?

General MEDARIS. The problem is one of timing, Mr. Congressman. It depends to a great extent on the time when we can expect to have available a successful and reliable atomic powered propulsion system.

Now, as far as the other fuels are concerned, we have explored the entire spectrum. We know where the possibilities are, and we feel

that the atomic-powered missile of reliable character is far enough off that the intervening gap should be covered by further progress in the area of the so-called exotic fuels, chemical engines.

Mr. FULTON. Do you think that more emphasis should be put on the hypergolic fuels that ignite on contact rather than the oxidation fuels?

General MEDARIS. The best of the oxidation fuels are also hypergolic. They are not monofuels.

Mr. FULTON. On the second stage, right now, of the Vanguard weapon we, of course, use the hypergolic fuels. The question I am raising is: Should we, on that intermediate stage, put more emphasis on the development of that type fuel, or should we just simply put the emphasis on the solid and the rubber-impregnated or artificially rubber-impregnated fuels?

General MEDARIS. The solid fuels, I believe, are consistently going to lag behind in their ability to give us the major areas of thrust that we want. Now, they are supreme in their field, but it is sort of like the difference between a diesel engine and gasoline engine, you don't use them for the same application.

Mr. FULTON. Where should the pressure be put on the development of new propellents? Should it be on the latex pressurized solid fuel, on the hypergolic fuels?

General MEDARIS. We think in general it is on the hypergolic chemicals. We would like to be into a program right now of developing an engine at about a third of a million pounds which could be multiplexed against a known combination which I would prefer not to put in the record, which will give us a substantial increase in efficiency and which we know we can handle.

And we would like at the same time to be into a reduced applied effort at a reduced scale of thrust for upper stages of the next stage beyond that which we believe from analysis is the best chemical fuel that we could ever tolerate, and the next step from that is your atomic rocket.

Mr. FULTON. That is the first step I am trying to come to, and I appreciate your saying it.

How much would the original step that you have spoken of in the hypergolic fuels cost and what would be the amount of time that would be involved on such a research program?

General MEDARIS. I believe we can come to this intervening step of a third of a million pounds, we can come to that in a matter of a minimum or a maximum, I should say, of 3 years. We could have an effective operating engine.

Mr. FULTON That would really permit us, then, to put into orbit a manned space satellite of some size?

General MEDARIS. Yes; because it could be multiplexed in 3, which is a very efficient engine, incidentally, and possibly much larger than the ton size that the Soviets are now speaking about.

Mr. FULTON. Also, it would give us not only surveillance but also military capability of a manned space satellite.

General MEDARIS. The size potential out of such an engine combination I am talking about, in terms of a multistage vehicle, would pretty much let us choose what you want to put in.

Mr. FULTON. That would be able to come in what period of time, if we put the push on an urgency program to get one-third of a million pound thrust engine?

General MEDARIS. Well, this goes through steps. All of this is outlined in this coordinated program.

Mr. BROOKS. Have we spent enough money on solid propellents for fuels?

General MEDARIS. I think so, in that area; yes.

Mr. BROOKS. Were we slow on getting into the development of solid fuel?

General MEDARIS. No, there were certain fundamental breakthroughs that had to come through in the research area before we could go forward.

Mr. BROOKS. All these breakthroughs are available to us now?

General MEDARIS. That is right. It is now a question of advancing, of engineering, more efficient motors, more stable against temperature changes, having longer storage life and somewhat greater efficiency.

Mr. BROOKS. What about the liquid fuels? Have we reached about the limit in the progress of development of liquid fuels?

General MEDARIS. There are at least two major steps more that can be taken in liquid fuels.

Mr. BROOKS. You would change the constitutent parts?

General MEDARIS. That is right.

Mr. BROOKS. And new constituent parts would give us considerable progress?

General MEDARIS. That is right.

Mr. BROOKS. You still would place more emphasis on liquid fuels than solid propellents?

General MEDARIS. For your heavier carriers, they can get there faster than your solid propellent in these areas.

For the thing we are talking about, you need high thrust for a long period and it will take quite a long time before you can get solids in that area.

Mr. BROOKS. Liquid fuels are more difficult to handle, are they not?

General MEDARIS. It is purely an engineering problem. When you consider the problem of getting the solid fuels into the rocket in the first place, if you consider that as part of the difficulty, the answer is no.

Mr. BROOKS. Of course, if you are thinking exclusively of long-range missiles, where you have a launching base, but you have a shorter range missile, the liquid propellent is not as transportable.

General MEDARIS. We are moving as fast as possible on the solid in the shorter range missiles.

Mr. BROOKS. I have thought for some time we have not been giving the emphasis we could on propellents and we were putting the emphasis on rockets instead of propellents.

General MEDARIS. There has been a lot of emphasis on both.

Mr. BROOKS. Your command, by its name, has control of missiles, but do we have a command that has the obligation of developing propellent materials?

General MEDARIS. We have this likewise, as far as the Army's responsibility.

Mr. BROOKS. A separate command?

General MEDARIS. No, sir, it is within my command.

Mr. BROOKS. You think we are placing emphasis enough?

General MEDARIS. I think relative to the place it has in the whole area and the virtues of the solution, we are placing adequate emphasis on it.

Mr. BROOKS. I could go along and not have any recess, but we have a man here who has done yeomanlike duty in taking these notes. He has to be back here again at 2 o'clock.

Mr. FULTON. Also, for the record, Mr. Chairman, I should like to say that the reporting service rendered by this gentleman here, during the course of these hearings, has been about the best I have ever seen.

Can we ask how much money you would like to have for a third-of-a-million-pound-thrust engine?

General MEDARIS. A development program in terms of $50 million.

Mr. FULTON. $50 million would give you an urgent space program that would adequately move us ahead in that field?

General MEDARIS. I think so.

Mr. BROOKS If there is no further business, the committee is adjourned until 2 o'clock.

(Thereupon, at 12:40 p. m., the committee recessed, to reconvene at 2 p. m., same day.)

AFTER RECESS

(The committee reconvened at 2 p. m., Representative Overton Brooks presiding.)

Mr. BROOKS. Will the committee please come to order?

The Chairman, Mr. McCormack, has just called and said he would be a little bit late and he has asked us to go ahead in his absence rather than to delay the hearing.

We are always glad to have General Gavin. I have had the good fortune of hearing you testify before, but I look forward with just as much interest to your testimony on this occasion.

General, do you have a prepared statement?

STATEMENT OF LT. GEN. JAMES M. GAVIN,[6] RETIRED, FORMER DEPUTY CHIEF, OFFICE OF RESEARCH AND DEVELOPMENT, ARMY

General GAVIN. No, sir; I do not have a prepared statement. I have appeared before this committee in executive session. Upon request of the chairman, I agreed to make myself available when I could.

Mr. BROOKS. Do you have a general statement you want to preface these questions with?

General GAVIN. May I say, then, to the best of my memory I would repeat what I said a couple of months ago. First, I am far

[6] GAVIN, James M., army officer, b. New York, N. Y., Mar. 22, 1907, s. Martin Thomas and Mary (Terrel) G.; B. S., U. S. Mil. Acad., 1929; grad. Inf. Sch., officers course, 1933, Command and Gen. Staff School, Parachute School, married 2d, Jean Emert Duncan, July 31, 1948; children—Caroline, Patricia, Aileen, Chloe, 1 daughter (by previous marriage), Barbara Margaret. Enlisted as private United States Army, 1924, commd. 2d lieutenant, inf., 1929, and advanced through the grades to major general, 1944, as commander 505th Parachute Regimental Combat Team, landed with command by parachute, Sicily, July 10, 1943, Salerno, Italy, September 13, 1943; as assistant division commander 82d Airborne Division, landed with command by parachute, Normandy, June 6, 1944, as div. comdr. 82d Airborne Div. landed with command by parachute in vicinity of Nijmegen, Holland, Sept. 17, 1944, participated in reduction of Ardennes penetration, 1945; dep. chief of staff for plans and research, 1955—. Decorated Distinguished Service Cross with oak leaf cluster, Purple Heart, Silver Star, Distinguished Service Order (British). Author. Airborne Warfare, 1947. *Address: care Secretary of Defense*, Washington 25, D. C.

from authoritative on the subject of space. There are no doubt many more able spokesmen on the subject than I. I have, however, been associated with it since Dr. von Braun and the Secretary of the Army Stevens and I and General Ridgway talked over a proposed satellite program back in 1954.

In the meantime I have learned the language and have done a great deal of studying. In the meantime, I have taken an increasing interest in the subject. I am particularly interested in the military aspects of the program, feeling that they were of tremendous significance.

Appearing before Senator Johnson's committee on December 13 of last year, at that time I stated I thought that the solid rockets were the most significant in the military sense of that word, ahead of our times, which I still believe is true.

Other than that, I know of nothing that would be a substantive prelude to any questions you may want to ask me. I will gladly make myself available to you any way I can.

Mr. BROOKS. Do you believe, then, General, that this development in the satellite program has vast possibilities for the security of our country and for the progress of mankind?

General GAVIN. There is no question about it, sir; I absolutely do. The record is quite clear on this point.

I have addressed a half dozen memorandums to the Department of Defense over the past several years, seeking on behalf of the Department of the Army, authority to launch a satellite. I have worked in research and development and in weapons systems analysis for quite a few years and I am impressed, as I believe are all of us with any background in the science, with the need for understanding of the future, the need for vision.

The more dynamic the technology of the day becomes, the more you need to strive if you are going to survive. Obviously the satellite is the most tremendously impressive vehicle of our time. While we do not exactly understand its immediate military application and we will not until trial and test, the very basic functioning of it is adequate warning that it means a great deal, and we had better get after the satellite and do something about it.

Mr. BROOKS. And we had better do it first, too. Do you agree on that?

General GAVIN. No question about that.

Mr. BROOKS. You have said that you have made repeated requests for the development of the satellite program. What was the answer to these requests that you made?

General GAVIN. I would say that they were given a very good hearing and the replies were good evidence that they had been gone into quite carefully, but in conclusion they instructed me not to undertake a satellite program.

The last such memorandum I remember the wording of was one of May 1956, addressed to me in person, that concluded with the statement, rather, used the second person pronoun, "You will not undertake the satellite program using the Redstone or Jupiter missiles," signed by a Deputy Assistant Secretary of Defense.

Mr. BROOKS. What was the date of that?

General GAVIN. To the best of my memory, May 1956.

Mr. Brooks. That was before the trial of the Jupiter C, when it rocketed up 3,300 miles, because on September 20, 1956, in experimenting with the Jupiter C, you got it up to 3,300 miles.

General Gavin. That is correct, sir.

Mr. Brooks. So you got the red light on your program in May before then?

General Gavin. Yes, sir; we had from the beginning. Our concern stemmed from two sides of the problem.

First, we had analyzed our own capabilities in terms of the Vanguard with considerable care, and we were quite uneasy lest our country fail to meet its IGY commitment as it appeared to us we would. I will say to you frankly we thought in 1956 we would not get Vanguard up in the year 1958, as we saw it.

Mr. Brooks. That was an IGY commitment?

General Gavin. Yes, sir; we had agreed we would launch one and we were quite afraid that the scientists of our country would be quite embarrassed and our Nation, if we failed. We felt, next, it could be done, unquestionably, it could be done, if we were allowed to go ahead and then we were beginning to feel a trifle uneasy about the Soviet program.

We really were not as impressed as we should have been with it, however, until the spring of 1957 when it became quite clear then that they were making much greater progress than we had anticipated a year earlier.

As you know, in the summer of 1957 they announced having fired a long-range missile. At the time of Suez, of course, they threatened the use of rockets and in August of 1957 they announced—Mr. Khrushchev announced—that they had fired an intercontinental ballistic—he did not say missile—device that landed in the target area, some wording such as that.

All the evidence we had made it quite clear that they had reached outer space already. So in mid-1957 we were at the point of worry then.

Mr. Brooks. Do you think that the reference to a device that reached its target area meant that that was a satellite or do you think it was an intercontinental ballistic missile?

General Gavin. I am not sure what Mr. Khrushchev referred to, sir, in 1957, but I am satisfied that the state of technology in the Soviet Union is such now that they do have an ICBM.

Mr. Brooks. Do you feel they are way ahead of us in reference to this program?

General Gavin. I would say they are ahead of us.

Mr. Brooks. How far ahead of us?

General Gavin. It would be difficult to put a finite number on it. Sputnik II is a demonstrably bigger satellite than Explorer and Vanguard, and obviously would require a much larger main thrust unit and this immediately applies to ballistic performance. You have the remaining warhead guidance which, if they solve that properly, they have no problem. It is hard to say.

Mr. Brooks. Would you say they are ahead of us because our people were not allowed to go ahead with the program, or are they ahead of us because we have inferior scientists?

General Gavin. There is no question about the answer to that one. We have the scientific talent and we have the brainpower, the indus-

trial capacity and energy to do these things. The failure was in decision-making, making the wrong decisions.

Mr. BROOKS. The wrong decisions put us behind on the programs?

General GAVIN. No question about it.

Mr. BROOKS. If we get the right decisions now, with the talent and ability and with the proper amount of finance behind us, we can overtake the Russians, can we not?

General GAVIN. With a great deal of hard work; yes, sir

Mr. BROOKS. Hard work and long hours.

General GAVIN. Adequate funding.

Mr. BROOKS. And proper decisions.

General GAVIN. No questions about it.

Mr. BROOKS. I believe you added adequate funding

General GAVIN. Yes, sir.

Mr. BROOKS. Have you given any thought as to how much money we will need to get this thing going?

General GAVIN. No, sir; I am not in a position to put an actual dollar figure on it. I would express it this way: That we need a broad approach We must not worry about duplication in research. One cannot foresee the future so well that in research you can pick the one thing that is going to pay off and exclude all others, so you must spend money on research.

So by adequate funding I mean little restraint on funding for research. Spend money on research and it will pay off later on. The big decision in research and development is not when to start something, but when to stop something.

I know that the funding programs come before you gentlemen and I should say they should be fully funded in research and decision made where to chop it off later on.

Mr. BROOKS. How far were we retarded by these bad decisions? Would you say a year, 2 years, or 3 years, or how many?

General GAVIN. Sir, there are two aspects to this question With the state of technology widely appreciated and understood of about 2 years ago, decision then could have given us a satellite very quickly perhaps in a few months, so that we could have had a satellite up about a year and a half ago, something of that sort

But the other aspect of it is that by greater vision and a greater willingness to seek innovation in new areas immediately following World War II and a full funding of missile programs through the years 1946, 1947, 1948, 1949, 1950, I will say we could have had a satellite significantly ahead of the year and a half. Perhaps we could have had one—I do not know that I can put a number on this, but a year or two ahead of that.

Next to losing a war, the greatest danger that can confront a nation is to win it because having won it you become complacent and you assume that what you won it with will serve you in the future. There is a historical pattern that shows that this is one of the really great pitfalls of any people.

Preoccupation with a single weapons strategy that has won for us in the past is certain to bring us disaster in the future because you must look for new ideas and new innovations and we seem to have closed our minds to new ideas in the latter half of the 1940's.

Mr. BROOKS. The reason I ask v··· that is not to put the finger on anybody or to be critical.

General GAVIN. I understand.

Mr. BROOKS. Then you find no fault in the training of our scientists in this country or the capability of these scientists?

General GAVIN. Our scientists are as good as any in the world. Of course, I am quite biased as an American would be, but I do believe their record of performance is quite clear. Scientists are concerned with the schooling problem because it comes down to this in the last analysis. We are in a very dynamic technological age in which survival will be based on innovation and breakthroughs which come unexpectedly and completely change the pattern of strategy and tactics

Now, breakthroughs come in proportion to the minds on a problem. If nation A can put 1,000 brilliant scientists working in this new field and nation B 100, the chances are that nation A will come up with 10 more ideas in a given period of time than nation B, and the chances are they are 10 times more likely to come up with a breakthrough than nation B.

So it comes back, then, to the training of scientists and we should have a school program that gives our scientifically inclined youngsters an opportunity to go into the sciences, encourage them to go into the sciences.

This would not exclude the liberal arts, because we should push those things, too. This, I suppose, means that we should work harder in our schools in all these fields, liberal arts as well as the sciences.

Now, to get back again to the original answer, our scientists are top flight I have no reservation about that answer whatsoever. However, we should put our minds to the scientists in the future and be sure we have an adequate quality and quantity in the group coming along

Mr. BROOKS. That is a fine explanation. I want to ask you this question. You are out of uniform, now, and therefore you can speak freely. We appreciate that fact and it makes you a very valuable witness to the committee.

If you were down there in Redstone, what changes would you make in the program or the setup in the interest of developing the satellite, the rocket and the missile programs?

General GAVIN. The way the Army Ballistic Missile Agency and Redstone Arsenal is funded today, I doubt that I would make many changes. Frankly, I would probably have General Medaris and Dr. von Braun in, or I would go down and see them and wonder why they were not doing more and demand the impossible of them every few weeks or so and then give them money to go ahead and do it

But they are adequately funded. They have approved programs now and more cannot be done with those, but I would sure push them for new ideas.

Mr. FULTON. You were not here this morning when we did just that?

General GAVIN. I might say that while we have been awaiting this hearing we have been reading the old bulletins of the atomic scientists back around 1946 or so. It is an impressive state of affairs, the lack of ability to see where you are going in technology and it is interesting to go back and read 10 years back the statements and articles by our scientists of where we were going.

It is discouraging. Innovation is such a rarity it is very difficult to push through new ideas. I think the best thing that could be done in Redstone Arsenal would be to encourage them that they do more and demand that they do more.

Mr. BROOKS. In other words, give them a little more freedom in their thoughts?

General GAVIN. Absolutely.

Mr. BROOKS. And require more in the way of an effort. Those two things? Is that what you have in mind?

General GAVIN. Yes, sir; I would demand more of them and push them.

Mr. BROOKS. You think, then, we could make much better progress with those two concepts placed into operation?

General GAVIN. Yes, sir.

Mr. BROOKS. Mr. O'Brien?

Mr. O'BRIEN. General, I was interested in your statement about science education. I understand you feel we have a great need for scientific knowledge now, but our danger or concern lies in the future, that we must start now to make sure that the Russians do not get too far ahead of us in that particular field?

General GAVIN. Yes, sir; that is correct.

Mr. O'BRIEN. My question is this: What can we do to get greater benefit out of the scientific know-how we possess? The reason I ask the question is that a statement was made the other day that occasionally one of these projects is abandoned or terminated for some reason. Then you have a number of skilled people who are suddenly cut adrift who might go to private industry, or I do not know where they go. Then, when you go to another project, you have to reassemble a number of them. Is there any way of keeping such a force together?

General GAVIN. I know of none for the mass of the skilled scientific workers. We rather well keep track of our top scientists in this country and they are well known by reputation and we know the projects they are putting their minds to from time to time, but I know of no centralized way of controlling these people.

I believe I understood, too, your concern, because we are wasting a great deal of our scientific talent. Sometimes it is stockpiled by industry, too, in the hope of getting contracts, when it is needed badly in another area.

Mr. O'BRIEN. That is the thought I had, that it was stockpiled by industry. I was wondering if there was not some way that the Government could do some stockpiling in that field, perhaps by contracts or something of that sort.

General GAVIN. I know of no way that we could do it that I can recommend.

Mr. O'BRIEN. Do you not feel much of our weakness in this whole field has been the fact that all of us respond largely to panic? In other words, we demanded immediately after Sputnik a crash program in science education. The creation of this committee and its counterpart in the Senate came about as a result of our excitement over those things and sudden realization that the Russians were ahead of us.

Now, do you not think that while we are attempting to catch up that we should concentrate more on leapfrogging and getting ahead of them?

General GAVIN. I am glad you asked that question. I would agree, yes. I read once again the statement that came from our scientists on March 26 about the subject of space. I thought the best sentence was the vary last one. It reads:

> It therefore appears wise to be cautious and modest in our predictions and pronouncements about future space activities and quietly bold in our execution.

There has just been too much alternating between hysteria and elation and not enough steady hard, solid work. We are going to have to get down to business if we are going to get ahead now.

The other point you mentioned, of course, is one that was quite fundamental in this situation, and that is the tendency to surrender the technological initiative and lead to someone else. If we do that we will never survive. We have to strike boldly on our own.

This applies in this situation. I recall specifically on December 13 hearings in Mr. Johnson's committee the question was asked of numerous witnesses, "What is more important, a missile program or a space program?"

To my surprise, many of them said a missile program. Well, this could not possibly be so because we are in the space age and a space program includes a missile program. You cannot get space vehicles up without missiles and a space program is far more important.

You will find the record will show that many people turned their mind against space and just said missiles because missiles then were in the headlines and the Soviets were threatening us with them and they were being used, and so on.

We will never survive without striking out boldly and lead the parade of progress and let other people follow us.

Mr. O'BRIEN. You feel this committee, for example, in addition to providing the so-called hardware for going ahead with the things we have already developed, should make substantial provision for pure research to permit certain people working for the Government to come up from time to time with something that is new and radically different from the things we propose to manufacture at this time?

General GAVIN. Absolutely I would certainly agree with that.

Mr. O'BRIEN. Thank you very much.

Mr. BROOKS. Mr. Metcalf?

Mr. METCALF. General Gavin, one of the functions of this committee, and one of our missions, is to find out where to put this whole space thing in the Government. The President sent up recommended legislation. In his recommendations he said:

> I recommend that aeronautical and space science activities sponsored by the United States be conducted under the direction of a civilian agency except for those projects primarily associated with military requirements.

Do you agree with that?

General GAVIN. Yes, I agree with that entirely.

Mr. METCALF. What sort of civilian agency should we create?

General GAVIN. Of course, most of us consider this, I suppose, in terms of our recent experience with the Atomic Energy Commission and I remember the arguments when that was established.

I remember, too, that few people saw any application for fission except a military application. It is quite interesting to go back to 10 years ago about the future of fission. Very few people saw the widespread civilian application of the products of fission. Today

perhaps they are 90 percent of the program and the military business is a very small part of it.

So I am thinking along the lines that we have developed the Atomic Energy Commission because I do believe that the civilian application of the space program will be far more important than the military. So it should be under a civilian agency. Furthermore, you would disassociate it from service problems, service budgeting problems which can become very serious in peace.

I should think it should be and it can be done and the military programs can be conducted as they are today, through the congressional committee. I know the Military Application Subcommittee of the Joint Atomic Energy Committee has worked very well and I know that the programs are moving along very well and our country has good reason to be proud of them.

We are developing weapons that will serve our people and we are packaging them in tactical form to give us an adequate air defense, a defense against missiles and give us weapons that can serve us and serve our Armed Forces. A great deal of that is due to the inspiration and impetus given us by this committee.

I would think a parallel situation could readily develop in the space program and we could have a committee such as you gentlemen here and a joint committee push the program along and be able to urge the thing to be done without the restrictions that would come from military control of it. I think the proposal is a very good one.

Mr. METCALF. General Gavin, as you know, the recommendations that have been sent to this committee by the President include an advisory board of 17 members, 8 from the Government and the rest from industry, who meet not less than 4 times a year. So that would be a part-time board in charge of this affair, advising the Director and the President.

Would you suggest, in your experience, that would be a better way of organizing this civilian agency or a full-time board such as the Atomic Energy Committee, composed of commissioners, composed of fewer men?

General GAVIN. I must say I do not know. I do not have enough experience to say. At the moment I feel that certainly, at first, it should be a full-time committee until we felt sure we had the situation in hand, but I do not know. I should not give an opinion on this.

Mr. METCALF. That is a decision that is going to confront this committee. I am in hopes that out of your experience you would point a way toward either a permanent committee or perhaps part-time.

General GAVIN. You know, I tempered my answer with the reservation that I would want to feel that the situation was in hand before we decided to meet occasionally from time to time. Let us have no illusion about this. The complacency is still running deep and strong in this country on the problem of space and just to appoint a group to meet once in a while or every so often to take care of things to me would not be adequate as I see the situation now.

I would want to feel it is well in hand before we go home and decide to talk about it months later. We have tremendously challenging problems ahead of us and they would deserve full consideration of very able men for some time

Mr. METCALF. Of course, as I understand it, this board of 17 men could meet oftener than 4 times a year. They could probably be in general session at all times, but they are not to be paid anything but their expenses.

It is understood, as I read the legislation, to be a part-time job. Like you, I have some misgivings about a part-time board in charge of this.

General GAVIN. I would certainly be inclined to share your misgivings. Of course, the recommendation may be based upon the advice of some of the fine scientists or advisers or executives and they may be sound, but I am concerned.

Mr. METCALF. I have this question on the business of an advisory board which advises the President and Director rather than a board that has control over the Director.

Do you have any comment on whether we should create a commission to have the control or put the control in the Director and have only board members in an advisory capacity?

General GAVIN. I am not sure until I know more about it. I have not read the draft of it and it would not really be appropriate for me to give a judgment on it, I am afraid.

Mr. METCALF. I did not mean to put you in any position where you had to answer something for which you were not prepared.

General, I would like to read to you this declaration of policy from the administration bill:

> The Congress further declares that such activity should be directed by a civilian agency exercising control over aeronautical space research sponsored by the United States except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations, in which case the agency may act in cooperation with or on behalf of the Department of Defense.

Now, I am unable to find out from that language whether the civilian agency has control over the military part of the program. If you were a general in charge of the missile program, what would your interpretation of that be?

General GAVIN. I certainly would want to get my hands on a copy of it and read it with care. I am not sure without studying it what it would mean. I am sure I would want to talk to the people who wrote it. It does not sound to me like the management procedure used with the AEC in which they have authority to go ahead with the programs given to them by the Department of Defense.

It seems unnecessarily vague and lends itself to misunderstanding at the present moment.

Mr. METCALF. It would seem to me that it probably would not give the Department of Defense enough control over the purely military part of the program.

General GAVIN. Well, if the Department of Defense specifies what it wants, this commission then could see to it that it gets it. The Department of Defense does not of necessity have to control the industrial process or the research programs that get the hardware for them, although I realize they are doing a great deal of that now and they will.

But as I understand it, in addition to what the Department of Defense is doing, this commission will conduct the program by activity or direct activities which may be applicable to the military programs.

Mr. METCALF. As I understand your forecast and prediction, most of the programs conducted will be civilian programs, as this space thing goes along.

General GAVIN. I am personally of that point of view; yes.

Mr. METCALF. Thank you, General.

Mr. BROOKS. Mr. Natcher?

Mr. NATCHER. General Gavin, do you believe that science deserves a place in the Cabinet?

General GAVIN. Yes, I do.

Mr. NATCHER. Realizing the importance of our missile and satellite program at the present time, General, why not just have all of face the facts and realize it is going to cost us a lot of money and proceed accordingly? What do you think of that?

General GAVIN. Of course, that is a good idea. We want to be awfully careful not to get our scientists mixed up with politics to the extent that they are subject to the changing political atmosphere of the Capital, you know. They themselves are not of the turn of mind that would adapt well either to political environment.

Nevertheless, I have thought about this a great deal. My hesitancy in answering was not based upon lacking conviction on a point of view. I do think we should have a top scientist in that position. How to fit him in I am not sure. He should be protected from the vicissitudes of political change that occur around Washington.

Mr. NATCHER. Do you feel that the Government has properly informed the people of the demands of a technological war?

General GAVIN. That the Government has?

Mr. NATCHER. Yes; our Government.

General GAVIN. Sir, that is not for me to say. Obvious overt efforts have been made to inform the people through television programs and the like, and I think they have been impressive and informative.

If our Government considers that adequate, I would not be the one to say that it is not.

Mr. NATCHER. General, do you feel that at the present time we are pooling our scientific knowledge with our allies as we should and receiving the benefits that we could from our allies?

General GAVIN. No; we are not.

Mr. NATCHER. Thank you.

Mr. BROOKS. Mr. Sisk?

Mr. SISK. General Gavin, I am happy to have you before the committee again.

Just to pursue briefly the line of questioning that my colleague, Mr. Natcher, brought up with reference to our allies, is it your opinion that they could contribute a great deal through a proper coordination and a sharing or pooling, let us say, of scientific knowledge and research and development procedures?

General GAVIN. Yes. You know, we all realize that we have no monopoly on scientists, that some of our best scientists have come from Europe. Some of our outstanding scientists are not Americans by birth.

Now, I have spent quite a bit of time in NATO and I look upon the North Atlantic Treaty Organization as really being one of the great instruments of our time, that absolutely must be effective and must work. Collective security is the road to survival for our country.

Yet, one of the most bothersome problems is the free exchange of scientific information. I do not say that the United States is at fault exactly. We all contribute to the problem. But there is a great deal of duplication.

There is a lack of exchange of information, and we are not sharing our thinking and not sharing the work. I wish we were doing much better in this respect. It would bode much better for the future of NATO. This is fundamental to confidence in NATO. We are not doing a good job of it.

Mr Sisk. Do you have any specific recommendation, General Gavin, on how we might facilitate that exchange, either through NATO or through some other vehicle? I think that is important. I am wondering if in your thoughts on this, and particularly in relation with NATO, if you have any specific recommendation.

General Gavin. Yes; I do. Without putting it in the form of a draft, let us say, we get so ensnailed in our own redtape that we cannot get out of it The security restrictions now on certain information are such that we cannot get the ideas across that we should be able to, to ready NATO for the technological age in which it finds itself.

First of all, therefore, the Department of Defense should at least be asked, although they could well take the initiative and ask that legislation be drafted that would enable them to amend the present security restrictions that are so binding and when this legislation is passed and they could go ahead and exchange, then, of course, we could do it.

At the moment, again, you have certain laws, then you have certain directives from the Department of Defense. Then you have certain regulations in a service. When you finally get down to the man who must sit down with another man in uniform in NATO headquarters to get an idea across, he simply cannot do it.

Atomic matters, in particular, are a difficult subject. It stems from the law of the land. The Department of Defense could ask to change it; it might be a good idea to do it that way by proper legislation. Proper encouragement from Congress would enable the Department of Defense to do much more in this field.

Mr. Sisk I would understand your recommendation to mean that through legislative action and possibly through directives from the Department of Defense, we could cut a lot of redtape. It would be necessary to do that in order to bring about any exchange or joint action with our allies in this type of development. Is that correct?

General Gavin Yes; absolutely.

Mr Sisk. Now you mentioned a little while ago a fear of complacency. As I understand it, you fear that we have too much complacency in this country in spite of recent events. Is that correct?

General Gavin. I would say I think so. Perhaps I have been too close to the problem, but I think so.

Mr. Sisk. I might say, General, I share with you that feeling. I have just returned from my own district, as other members have, and unfortunately I think that our people have no realization, to a large extent, of the importance and of, let us say, the mortal danger in which our country and our way of life may be.

I will ask you this. I realize you may not even wish to comment. Do you have any recommendation as to how we might awaken or in

some way snap the people—and I am referring to us here in Congress and the Government, which after all is all the people—out of this sense of complacency and bring us to a better realization?

General GAVIN. Well, sir, I share your feeling about being in mortal danger which increases with each passing day. But I really do not feel it is appropriate for me to comment on what can be done about it.

It seems to me it is a very fundamental problem and there is nothing much I could add to our common understanding of that, I think.

Mr. SISK Do you understand, in order to do the things that certainly some of us feel should be done in making it possible for you and others who have knowledge and understanding to move ahead with the rapidity which we feel necessary in this field, we, of course, must have the national backing, the backing of all the people? Of course, that is where it becomes essential, seemingly, to me, to awaken everyone from this sense of complacency. And yet, frankly, it seems hard to pin it down as to what we must do. Heretofore, it has been necessary to wait until the bombs are dropping before we snap out of it and we begin to do some things. With the things we face now, that will be way too late.

General GAVIN. Yes; in fact, I think the electorate is ahead of the Government. The people are ahead of the Government. They are more concerned than the Government is.

Mr. SISK. I appreciate that statement. Maybe we here are more asleep, in your opinion.

General GAVIN I say it not because it is the thing to say, because I think Congress is a better barometer of the situation than any other branch of the Government. Congress is more concerned, I would say, than any other branch of the Government. I have been out to the people in the last few weeks. The questions they ask are penetrating and the people are concerned and quite worried.

Mr. SISK. I have one other line of thought, General Gavin, and that has to do with what I would call the arsenal type of research and development program as against the 100 percent contract type of a weapons program. I do not know whether I make myself clear.

General GAVIN. I know what you mean.

Mr. SISK. Will you comment on that? That is of some considerable concern to me, and I know it is to some other people because they have asked me about that.

General GAVIN. I will comment on it and say that I have given that a great deal of thought in the past 4 years, particularly since I have been associated with the arsenal system intimately and with other systems. We have talked about the subject exhaustively. It would appear at first glance that if this country is to survive only the most intimate association between our armed forces and industry would enable us to survive and if American industry has the drive, the energy, the imagination that it professes to have, if it can make these television sets, big fendered automobiles, all the plastic things that no one else in the world is thinking about, surely, therefore, it has all the energy and imagination to push ahead in military programs if adequately funded, and therefore, if the competitive system, which is the essence of our democratic system, is going to compete favorably with the totalitarian government only the most intimate association of the armed forces and industry will enable us to do this.

This appears to be a very valid argument. Unfortunately, it does not stand up because the very features in our system that cause competition are the very things that keep the armed forces from moving ahead. Specifically I mean that if the armed forces became so close and totally embraced by a particular industry, soon they find themselves buying things that are obsolescent that they don't need, they cannot shake it off. They find themselves buying things that were long ago obsolescent because industry wants to sell them.

Industry urges that they be bought. They put out attractive brochures to advertise them. Soon you find the services buying things that they are forced to buy, practically. The visionary in the service, the military scientists, the people that see the future, who say it is wrong, cannot shake themselves loose from the system they themselves have gotten into and the thing they themselves have brought about The advantage of the arsenal you see is the defense parameters. It does not have to compete with industry. In most cases it does not It has parameters and it calls on scientists for advice and it knows what it requires of a certain amount of national product in certain fields.

It evaluates what industry gives it. It advises our military service as to the direction in which it should go. Then they can go and get what they need. The arsenal therefore gives you a degree of independence from industry that is essential to shaking off obsolescence and achieving innovation from time to time. So there are advantages in the arsenal system despite the first argument I gave you which seemed to establish the point that only the most intimate association with industry and service and rejecting the arsenal system is best.

I don't believe it is. The answer? Well, we need a reasonably controlled arsenal system You need some way to assure that the taxpayer gets his dollar's worth for the dollar spent. You need, too, the main reason, the closest association between the service and industry. There is no black and white simple answer to the problem. Certainly the answer is not to reject the arsenal system. I would not do it.

Mr Sisk I appreciate your comments very much. I have felt, and I may be wrong in this, that to some extent we have seen demonstrations of that in what the Army has been able to do at Redstone with the Redstone and Jupiter C as compared to a great deal of money that has been poured by a contractual arrangement into some other systems which, unfortunately, have not developed.

I certainly, of course, am all for American industry. It has tremendous powers of production, particularly the assembly-line type. That is where my concern comes in. Do we get so involved in the desire for assembly-line production when we are in a field here where every day you make some new discovery and the need to make minor changes or make changes can only be done in the arsenal-type operation?

General Gavin Yes The development of the Redstone, the Jupiter C and the Jupiter, are illustrative, in my opinion, of good management of an arsenal because the Army is not producing those missiles, as you know. They are being produced by industry, Reynolds Metals, Chrysler, Ford Instrument, and so on. I must say without pointing a finger to any specific individual or any industry, I worried frequently during the past couple of years lest unfavorable

decisions coming to the Department of the Army did not in fact reflect industry pressure on our Government, on the Department of Defense.

You see what you end up with. You have thousands of employees in areas who must be continued in employment and industry cannot simply be chopped off with this expensive unemployment resulting. Yet, you cannot continue to support them if the product is not worthwhile and if it is only going to lead to military disaster in the long run. And yet I felt that the industrial pressure upon decision making processes were unfavorable to Redstone Arsenal despite the good hard work it was doing on a very austere basis to come up with the end product we needed but it is a situation with which we must live. I see no easy way out of it.

Mr. SISK. I have one other question. You are probably familiar with this question because it has been tossed around in the past 2 or 3 days. Do you agree with Dr. Von Braun and General Medaris that there are specific objectives, important objectives, to be gained from a project which would place a man 150 miles into space, something similar to what was proposed by Dr. Von Braun the day before yesterday. It was mentioned by General Medaris under questioning today?

Or do you in turn agree with someone else who indicated it was just some sort of a stunt and did not have an importance?

General GAVIN. Like shooting someone out of a cannon?

Mr. SISK. Yes.

General GAVIN. They both have something in common. You have a great source of energy which tends to cause the human to defy gravity for a short period of time, but at that point they depart because humans are not going to travel by being shot from cannons, but they are going to travel in missiles. We have to learn to walk before we run. The problems of housing a man through this experience, as brief as it may be, will contribute in the long run to using manned missiles. I see nothing but good coming from it. So I am inclined to go along with it. I agree it should be done.

Mr. SISK. Thank you.

Mr. BROOKS. Mr. McDonough.

Mr. McDONOUGH. General Gavin, I got the impression from your answer to the red tape and the problems that we are facing in carrying on this program that it is more difficult to make progress under a democractic form of government than it is under a dictator form of government. Do you agree with that?

General GAVIN. It depends on what you mean by progress. I would not say that is so at all. We have our problems, of course, but they are symptoms of a very healthy condition beneath. A totalitarian form of government makes quickie decisions of course and can make quicker bad decisions, too.

Mr. McDONOUGH. You think we can compete in a democratic form of government?

General GAVIN. Yes, absolutely. We need more tolerance of new ideas and people with new ideas.

Mr. McDONOUGH. You also stated that you thought it would be a wise thing to have a scientist in the cabinet?

General GAVIN. Yes, sir. I have thought about this quite a bit. I have been of the mind for some time that this is so.

Mr. McDONOUGH. Would you not qualify that by specifying what kind of scientist? After all, science covers a tremendous field. You are talking about a physicist, a type of man that knows something about, well, space technology, what we are talking about?

General GAVIN. Yes, I would. He would need to be more of a managing scientist or a scientist himself but he should understand the broad field of science and understand handling scientists, which is something in itself.

Mr. McDONOUGH. Don't we have such a man in Dr. Killian?

General GAVIN Perhaps we do. In fact, this is what he is in a way, although he is not a Cabinet member.

Mr McDONOUGH. That would not add to his ability at all by putting him in the Cabinet.

General GAVIN. Not at all If he would sit as a member of the cabinet and have all the authority to contribute that a member of the cabinet has, he might be better than if he were actually contaminated by too much political association, in the Cabinet as a Cabinet member.

Mr. McDONOUGH. What was the word, "contaminated"?

General GAVIN If you will forgive the word "contaminated."

Mr. McDONOUGH You also stated some time back you and Von Braun and General Ridgeway talked about space exploration and development and your ideas were canceled out by an assistant secretary of Defense?

General GAVIN. Yes, sir We were in the original Orbiter program and finally a DOD committee came up with the Vanguard solution and we went along with that. We merely reclaimed it from time to time in writing, asking that we be allowed to go ahead.

Mr. McDONOUGH Who was responsible for the cancellation of the Orbiter project?

General GAVIN. I am not sure that anyone can say one man. Of course, the Secretary of Defense is the man responsible for all in the Department of Defense, but I cannot say.

Mr McDONOUGH What year was that?

General GAVIN We first started with the Orbiter program and then you see a committee was appointed, the Stewart Committee under Dr Stewart, to consider all satellite proposals because other programs were then brought up by the other services.

The committee came up with recommendations that went to an assistant secretary of Defense who I believe—this should be certified at the time—was Mr. Quarles. Then of course his decision was supported by the Secretary of Defense

Mr. McDONOUGH The Orbiter program was canceled out in favor of Vanguard?

General GAVIN. That is right.

Mr. McDONOUGH. If you had proceeded on the Orbiter program, do you think you could have had a satellite in the air before Vanguard put one up?

General GAVIN Yes. If we had been allowed to use the Redstone main thrust machinery, yes.

Mr. McDONOUGH Do you believe, in the situation we are in now, in pushing ahead with this program, that we ought to have one line of command rather than a diversification of ideas from two or three bureaus or departments?

General GAVIN. You have one line of command and a diversification of ideas. By having it as proposed under a commission, underneath that you could have a full diversification of ideas.

Mr. McDONOUGH. But you would have one person making a decision that we are going to do this and we are going to proceed to finish it?

General GAVIN. That is right.

Mr. McDONOUGH. You think that is the way it ought to be?

General GAVIN. It is sound in business and I think it is sound in military business, too, hold one responsible for the job.

Mr. McDONOUGH. Your interest in space technology and space military techniques goes back to the early stages of our development in this country?

General GAVIN. Yes, sir; I would say so.

Mr. McDONOUGH Do you think that the stimulus for satellites and space travel in Russia was stimulated by their capture of German scientists following World War II, or did it precede that?

General GAVIN. I don't think so, very much. They have a record of scientific curiosity, let us say, going way on back. They have turned up some fine scientists and creative thinkers in past years in other fields, and I think it was a normal thing. What the Germans contributed to it I am not sure; probably not a great deal.

Mr. McDONOUGH. You do not think we are proceeding as fast as we should at the present time?

General GAVIN. When I last was associated with the program we were not, no, sir.

Mr. McDONOUGH Are we now?

General GAVIN. I don't know, but I doubt it.

Mr. McDONOUGH. That is all, Mr. Chairman.

Mr. BROOKS. Mr. Fulton.

Mr. FULTON. I am glad to have you here, General. Do you think there should be a separate command structure within the various services leading up to the Department of Defense for this type of space development and missile work?

General GAVIN. No, I don't see any need for that.

Mr. FULTON. You see no need, then, for a separate command structure in the various military services that would have access directly to the top without going through the various echelons?

General GAVIN. No. The word "need" is very important in that question. I see the need. At the moment it is rather new. Like all new things it has to be done this way, but in time, space in the military service will become as normal as missiles and airplanes and nuclear affairs are now. I do not see the need for a special organization. The word "need" is important again.

Mr. FULTON. The Russian system is now headed by a Deputy Minister of the Presidium who is a general, General Kitinov. Do you think it should be in our setup, because that has been so successful, headed by a military command rather than a civilian command?

General GAVIN. No, a civilian command, a civilian agency rather than command.

Mr. FULTON. When the setup is proposed by you, that a scientist be put in the cabinet as a separate department with a civilian cabinet head, would that mean that the research and development of space

and missile programs would be taken out of the military organizations, as such, and put over under his lead or management?

General GAVIN. Well, sir, may I say that I did propose that in answer to a question whether or not I thought it was a good idea. I said I thought it was, and that is a little different. Now I think it would be well to have a scientist on the cabinet level close to our executive. There is no implication in such an undertaking of the service losing their own scientific program or control, either. I do not see this at all.

Mr. FULTON. You would then continue ARPA as it is right now?

General GAVIN. Yes, I would.

Mr. FULTON. Would you have a firm statement in the legislation that would restrict ARPA to definite military projects and programs?

General GAVIN. Of course I am reluctant to answer that question in isolation, not knowing what else you are considering in this legislation. But as I understand ARPA, it is military and should be preoccupied with the military problems to the exclusion of others. My answer would be yes, but I would like to see the entire legislation.

Mr. FULTON. Would you have a transition period from military to civilian control that extended from perhaps 1 to 3 years, or do you think it can be done more quickly?

General GAVIN. I think it can be done quicker.

Mr. FULTON. You have said that you felt that certain programs should be speeded up. Do you think that the ion rocket, which now has a lead time of 10 years, should have more emphasis, which I do believe?

General GAVIN. I do not know what is causing it to have a lead time 10 years now. If it is inadequate funding, then it should be stepped up. If we just simply cannot see our way through to achieve the technical goals that will lead to its accomplishment any sooner than 10 years, I don't know what can be done about it, but I know it is a component of space travel.

Mr. FULTON. You think the "Old Pokey" program at Los Alamos is moving fast enough?

General GAVIN. Which program?

Mr. FULTON. Old Pokey, an Air Force rocket research program at Los Alamos.

General GAVIN. I do not know enough about it.

Mr. FULTON. Do you favor research at the present time in photon propellents or equipment?

General GAVIN. Of course.

Mr. FULTON. Do you think a research program on a photon rocket or a missile or a space vehicle is practical at the present time?

General GAVIN. Yes At the present time it is entirely theoretical and yet by dealing with the theory we will soon be able to put in more finite form what such a propulsion system will look like and as soon as we can apply it in space we should go right on with it. To me this is very much a part of the space program and should be given as high a priority as anything in the space program.

Mr. FULTON. Is there enough emphasis being put on propellents and the development of the various categories of propellents, liquid and solid, or would you emphasize one over the other at the present time?

General GAVIN. Well this, much like the other question, in a way is difficult for me to answer because I am not sure specifically what is being done now. When I was working in the rocket business and missile business we were having great difficulty getting funds to do anything other than specifically approved projects which were at the time the Redstone and Jupiter and the Jupiter was being funded out of the other programs in the Department of the Army, anyway. So you were reluctant to push more work because it took money away from other programs.

At that time we were trying to get a solid propellent midrange missile underway and that took quite a long time to do So at the time I disassociated myself from these programs, actually about 6 weeks ago, I felt we were not doing enough. They may be now, I don't know.

Mr. FULTON. Would you tell us how you feel about the various programs that are now in progress? Are they getting adequate funds? Are they under pressure of urgency or are they moving along at an ordinary pace? When you were leaving, weren't you discouraged about the fact that they were not moving fast enough?

General Gavin. Of course I was. We could not get our satellite up and when we finally under the urgency created by the launching of the Sputnik, were again put in a position of making proposals, these proposals just rested week after week, month after month, without action. I am not sure but there may be some still around, I don't know, such as reconnaissance satellites, and like that. Yes, we were not responding quickly at all. The decision should have been made in hours to get the work underway. As I say, some may still be waiting to be made. I know some of them were not made for quite a long time. I am not sure of the situation at the moment, however. It is improper for me to say anything critical about them.

Mr. FULTON. Do you see an urgency for a program for the research and development of a third-of-a-million-pound-thrust engine or group of engines?

General GAVIN. A million-pound thrust?

Mr. FULTON. A third of a million.

General GAVIN. A third of a million is as fast as we could go.

Mr. FULTON. How about a third of a million that General Medaris spoke of at a cost of $50 million?

General GAVIN. I hope General Medaris is working on a third-of-a-million-pound-thrust unit now I talked to him about that in November and suggested that he get to work on it and scrape up a few odd pennies here and there down at Redstone Arsenal. We should have been miving on that before this.

Mr. FULTON. If you were given all the equipment necessary, the necessary scientific talen and research, as well as the facilities, and were given the word to go ahead on an urgency basis, how long would it take for you to take a shot at the moon?

General GAVIN. Again, the last time I discussed this with my people and with the scientists was about 90 days ago and at that time, given approval, we felt that we could do it within a year. Now, only from what I have read in the press, authority has been given to get the program underway, so I should say within a year we should expect results.

Mr FULTON. Do you think it would be a good move for the United States to have an urgency program for a lunar shot?

General GAVIN Unquestionably, yes, we have to.

Mr FULTON May I finish with this?

Do you think it is immediately necessary to institute programs to have nuclear propellents for rockets, missiles and space vehicles? Should we move at once into that field on a broad base, nuclear propellents, that is?

General GAVIN. Yes, surely You realize we are getting around the edge of rather classified programs, but of course there is a tremendous power source there For the investment you have to realize considerable range and considerable efficiency in lift, so it suggests perhaps beyond the chemical propulsion system and we should, as a matter of priority, go after the nuclear propulsion systems

Mr FULTON So this committee should make such a recommendation in its findings, in your judgment?

General GAVIN I would certainly recommend that.

Mr. BROOKS. Mr Keating.

Mr KEATING. Pursuing the questioning of the gentleman from California, Mr. Sisk, about complacency in this country, a very nice lady wrote me and said, "I see you are on the House Space Committee Don't you have enough problems on earth without getting up in space?"

Undoubtedly others have gotten mail like that. How do you answer that?

General GAVIN I would answer that this way: We have enough problems on the earth, but for the first time we can see through the potential of knowledge that exploration of space affords us, a way of solving the problems on earth, because I am convinced that through an adequate family of reconnaissance satellites, communication satellites, all under good management, and made available to an international agency such as the United Nations, we could prevent the outbreak of major conflagrations. You will never be able to keep some people from shooting at each other, no more than you in individual cities today keep individuals from engaging in little fracases, but the major ones can be brought under control. So I can see in the space program for the first time a clear possibility of lasting peace.

Mr KEATING. Thank you very much, General. I will send a lot of my correspondence to you for answering.

Pursuing another question, he asked about this pooling of information with our allies. I share your views that we should go further in that respect and I think the President has recommended it. However, I have had a study made by the Library of Congress and I have asked them to study the laws of other NATO countries as to the protection which they give to secret information. Some of them have almost no such laws, others have laws rather comparable to ours, and others have something in between. One or two have considerably stricter laws than ours

Now, you would agree that we could not share all our secrets with even our NATO allies, would you not, or how do you feel about it?

General GAVIN. Well, of course, there are certain things vital to national survival of them.

Mr. KEATING. I wonder if we should get to the point of this committee, as related to space problems, of making some recommendations in this regard? How do we get around that difficulty? Do we do it by some international accord of some kind? Do we ask our allies to strengthen their laws? I would hesitate, much as I feel we should pool more, much as I realize we would benefit from other countries by such pooling. I would hesitate with 2 or 3 of our allies to do that because of the complete lack of security laws on their statute books. Have you any suggestion as to a way around that?

General GAVIN. Hardly in useful specific form. I would reiterate once again my concern with the lack of up-to-date technical knowledge in the, let us say, military establishments of our allies. I have found in association with my colleagues from other countries and talking to them about the meaning of missiles, the meaning of nuclear weapons, tactical nuclear weapons, so often their thinking is almost exactly in a pattern matching ours of 5 and 10 years ago.

Yet I was not in a position to say more than just I thought you really ought to look at it this way, or that way. You finally have a condition of obsolescence in your military establishments of your allies which you see you cannot do anything about and this engenders a lack of confidence on their part, too.

We have this in Europe today. Perhaps through the NATO we could bring together the heads of government to form a committee within NATO to take a look at this and come up with a solution to it, but we must solve this problem. In fact, I am inclined to think now we are keeping things from each other that the Soviets know anyway. So this gets to be quite silly.

Mr. KEATING. I presume, then, it is true in some instances; probably in others it is not true. It has been a matter of considerable concern to me, sharing the view you have. But realizing the impediment created by foreign laws, it is a very difficult problem.

General GAVIN. Yes. You know, it really is. There is a considerable duplication, too, you know. If only the British could do one thing and we could do another, and the French another, maybe one would do electronics and radar, the other nuclear weapons in a certain category, and others in certain missiles, we would be much better off.

Mr. KEATING. There would be better savings.

General GAVIN. Yes.

Mr. KEATING. Lest there be any misunderstanding arise from a question put by the gentleman from Louisiana about Redstone Arsenal, the question was "Would you make changes there?" Let us get this pinned down.

You would not relieve General Medaris or Dr. von Braun, if you were in authority to do so, would you?

General GAVIN. No.

Mr. KEATING. I have been down there and I have been greatly impressed with the work of both those gentlemen.

Mr. BROOKS. May I say to the gentleman I don't want that inference drawn from my questions.

Mr. KEATING. I am sure that the gentleman did not intend that. But I wanted to get that very clear, because I was tremendously impressed with the work they were doing and the sense of urgency.

General GAVIN. Yes, they are doing a grand job.

Mr KEATING. Don't you think the sense of urgency is present there at Redstone?

General GAVIN It is certainly present there.

Mr. KEATING The chairman asked you to make some suppositions about the rate at which we have moved or could have moved. Let me ask you this, and see how close you come to the opinion of one of our other witnesses. If we had moved in this field like the Russians apparently did right after World War II, when would we, in your opinion, have had a satellite up?

General GAVIN. I would say perhaps about late 1953 or so.

Mr. KEATING. One of the other witnesses said 1951 or 1952. You would put it probably in 1953?

General GAVIN. Yes Who was it that said 1952?

Mr. KEATING. General Putt, I think.

General GAVIN. I would say Dr. von Braun would have a better idea. The state of propellents and the guidance systems and so on, component availability, there are so many factors that enter into this, I am not sure we could have gotten it up much sooner than 1953, but perhaps we could have

Mr. KEATING I want to ask you one or two questions about this proposed bill which is before us In the sentence which was read to you on the first page, the second sentence, it states

> The Congress further declares that such activities should be directed by a civilian agency exercising control over aeronautical and space research sponsored by the United States except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations in which case the agency may act in cooperation with or on behalf of the Department of Defense.

I envision that that sentence, and I think a comparable one which appears later, may be the subject of a good deal of discussion here in our committee when we get to writing a bill. That troubles me a little. I certainly share the idea of a civilian agency here, but I do not want to do anything to interfere with military operations in this field as they now exist or may hereafter exist

I wonder if we should not, for one thing, make it mandatory upon the agency to act in cooperation with the Department of Defense. Then, how do you interpret those words, "on behalf of the Department of Defense"? How would this agency act on their behalf?

General GAVIN I would presume that if the Department of Defense had something it wanted done the agency could act for it and undertake specific projects for it at its request

The language lends itself to a lot of bickering later on as it is now worded.

Mr. KEATING. That is what I was afraid of. I wonder if we should not try to pin that down a little bit, with a little clearer delineation of the proper missions of the two

General GAVIN. Yes. I would say it would be well worth while to ask the Department of Defense people, who are going to have to carry out this, what they think of it, what it means to them. But it should be worked over very carefully. It is a little too ambiguous now.

Mr. KEATING. I want to ask you about another provision of this bill. You had some discussion with one of my colleagues about the full-time or part-time character of this board. Now the board as set up in the bill is generally advisory in character, but in section 5 it sets up certain respects in which the board must be consulted by the

Director and those four areas are pretty broad. You voiced the idea that, perhaps at the outset, it should not be a part-time arrangement.

I have an open mind, myself, on that subject. Perhaps they should meet oftener than four times a year.

General GAVIN. Yes.

Mr. KEATING. If it were a full-time board or if men were devoting their full time to the activities, you would not recommend then a 17-man board, would you?

General GAVIN No, I would not think so.

Mr. KEATING. Have you given any thought to the size of it?

General GAVIN No, I really have not.

Mr. KEATING. But it should be substantially fewer than 17.

General GAVIN. Yes, 17 on a full time basis would be definitely a debating society

Mr. KEATING. That is exactly it.

Now just a couple of things more other than that. We have had quite a little difference of viewpoint or difference of approach here in our efforts to define outer space. Do you look on outer space as an area substantially different in kind from land, sea, and air, or just different in degree from air or atmosphere?

General GAVIN. Difference in kind and difference in degree, both.

Mr. KEATING. In other words, one witness drew a parallel in defining the atmosphere in the outer space with the sea, pointing out that there were different areas of density in the sea. I personally rather differ with that viewpoint I said to him it looked to me more like the difference between land and sea than the areas in the sea. Which of us do you think is closer to your thinking?

General GAVIN. I think it would be the one you don't like because by common usage now outer space has come to mean that area beyond where any substantial portion of the gaseous envelope about the planet exists, that is beyond the atmosphere. Then you are entering outer space. How far beyond that you want to go I do not know. Actually, by common usage there is so much talk about the planetary system or solar system as being outer space and then the galaxies are considered almost another order of magnitude beyond.

So I would be inclined to consider the area from beyond any substantial portion of the atmosphere remaining to include the planetary system of which the earth is one

Mr. KEATING. You would look upon that not only as a difference in degree but in kind?

General GAVIN. Yes, sir

Mr. KEATING. Now that leads me to this military question: Do you not feel that there should be a complete definition of the missions of our three services, if for no other reason, in the light of these space developments and because space might be the principal battleground of the future?

General GAVIN. Well, sir, space and the attendant problems are not an isolated phenomena of our time. It is part of the nuclear missile age. The significance of the sum total of all of these things is that the earth has shrunk to a very small size, physically, for combat purposes to the military man This implies at once a redefinition of roles and missions and redefinition of ways of exercising commands so as to achieve objectives in war. This more than space itself.

Mr. KEATING. But a redefinition of roles and missions in contemplation of their objectives, rather than where they ar to perform?

General GAVIN. That is about right, yes. I agree that is right. You could of course say the objectives in terms of tactical objectives and organizational structure they redefine those terms

Mr. KEATING. Because now the roles and missions are defined in terms of land, sea, and air.

The media in which they operate now all overlap and any service has a weapon that will involve exploiting media of all three, land, sea, and air, so obviously they overlap.

Mr. KEATING. Thank you.

The CHAIRMAN. Mr. Ford.

Mr. FORD. General Gavin, it has been my good fortune to have some contact with the Army's research and development program for the last 6 years No one has to sell the Army research and development program today I think the record speaks for itself It has been spectacularly successful. At the same time, I know your close association with it the last 4 years. I know something of your frustrations over the last 4 years even though, under your vision and leadership, it has grown within the Department of Defense with a budget of something below $30 million per annum to a budget now, as I recall, in the area of $150 million in fiscal year 1958. It is my opinion that through your vision and leadership the Army research and development program has really done a most effective job. I know that all during this period of time, some 4 years, you have felt that more funds, more programs should be available to the research and development. The frustration of trying to convince the Department of Defense, the Bureau of the Budget, and the Congress, must have been a difficult time as far as you are concerned. I just feel that everybody in the Congress and the public should recognize your magnificant contribution to our success in this area.

Now, one of the things that Dr. von Braun said when he was before the committee several days ago was that a significant breakthrough in the Redstone program in 1954 was really the thing that made a satellite feasible. Was that the breakthrough in the main thrust program?

He did not indicate precisely what he was referring to, but he indicated a breakthrough in 1954 resulted in the practicality of a satellite.

General GAVIN. Yes I would say that probably was in 1954. We had then to make a basic decision whether or not to drop a missile known as the Hermes, which had no growth potential, or go to the Redstone which we saw had a tremendous potential based upon the 75,000-pound-thrust engine. At that time we went for that. I would presume it was that because at that time there was no other significant change in prospect in what we were doing but that thrust looked good then and it paid off In fact, late in 1954 we decided we could do an IRBM, 1,500-mile missile.

Mr. FORD He also indicated that this breakthrough was something which would have followed automatically, if you had undertaken the Redstone program at any point following, we will say, World War II.

General GAVIN. Yes.

Well, again, he would have to answer for himself on that.

Mr. FORD. To turn to a question which has bothered me, because I am greatly concerned that we have no impediments placed in our weapons programs, I would like to refer to the language which has been discussed earlier, that which discusses language in the proposed bill.

To quote the language again:

Except insofar as such activity may be peculiar to or primarily associated with weapons systems or military operations, in which case the agency may act in cooperation with or on behalf of the Department of Defense.

I think we ought to recognize, first, that that is a statement of policy and not necessarily the language which directs the program. Has there been any impediment in this program with the ARPA setup as far as weapons and weapons systems are concerned?

General GAVIN. None of which I am aware of but it could well be that I would not be aware of them

Mr. FORD. ARPA could be a sort of forerunner of this agency since it has both control over the space programs that we have now in the three services and, to some degree, the weapons program as they relate to the service projects But there is no indication as far as you know that there is any impediment in the programs with the ARPA setup?

General GAVIN None at all. I must say I share your concern. You know, the really great obstacle we say has been decision making of a bad quality but those decisions usually have been to direct artificial limitations being placed on the program and looking back on this you don't understand how they have been able to tell any service, whether the Navy or Army or Air Force when they have a potential to contribute to national defense, you may not examine this or that, you may not research there, these things are incredibly harmful to the national interest. How they occurred I don't know, but they are no phenomena of our times. It has been the usual happening in the past. There must be absolutely no impediment caused by selfish industrial or any other interest in these programs. They must move ahead more freely than in the past.

Mr. FORD. Do you feel the proposal to have at least 1 person out of 17 on the advisory committee from the Department of Defense is adequate representation for the military in this kind of area?

General GAVIN. At this time, with that number, I would be inclined to think more. You would do better with more because a great deal of the competence in this area is now in the military service. I would suppose the composition of that committee could be changed later.

Mr. FORD Just to have enough people there who are knowledgeable in this area to make these decisions?

General GAVIN. Yes, I would say so.

Mr. FORD. Would you go to the extent of one from each service?

General GAVIN No, I would not ask the Department of Defense to appoint a certain number and I would not state what service they came from.

Mr. FORD. Civilian or military, representing the Department of Defense.

General GAVIN. Yes.

Mr. FORD. Not representing a service viewpoint?

General GAVIN. Right. This transcends that.

Mr. FORD. That is all, Mr. Chairman.

The CHAIRMAN. Are there any questions from any other members?

Mr. McDONOUGH. I have one question, Mr. Chairman.

Is the present rocket and missile thrust principle that is being used amplification of the original studies of Dr. Goddard?

General GAVIN. Yes.

Mr. McDONOUGH. Of course that is a principle that sufficient power will shove an object straight up from the earth?

General GAVIN. That is right.

Mr. McDONOUGH. Has anything new been discovered that Goddard did not know?

General GAVIN. The fundamental principles that Goddard wrote up are being applied worldwide.

Mr. McDONOUGH. Are the same principles being used by Russia as well as the United States?

General GAVIN. To the best of our knowledge, yes.

The CHAIRMAN. I do not know whether it has been covered, General. I had to be unavoidably absent because I am presiding over the House and I had to be there to appoint a committee to attend the funeral of the late Senator Scott. I could not designate somebody to do it, I had to do it myself as Speaker pro tem, otherwise I would have been here at 2 o'clock.

You have been associated with the space program going back to the days when Mr. Stevens was Secretary of the Army. Is that correct?

General GAVIN. That is correct, sir.

The CHAIRMAN. That was when you first proposed a satellite launching.

General GAVIN. That is correct.

The CHAIRMAN. You have taken an increasing interest in it ever since, dedicating yourself, your talents, your ability, and your experience to the consideration of this important aspect.

General GAVIN. Yes, sir, among other things.

The CHAIRMAN. You have certainly come to some conclusions as a result of your studies and your experiences.

General GAVIN. Yes, sir.

The CHAIRMAN. What significance do you attach to the present satellite situation, first from a civilian angle?

General GAVIN. I know this committee has had these points brought before it, sir. They are rather well known now.

We have the obvious one of weather, weather control, worldwide communications, not only electronic transmission of communications in written form but worldwide communications in television programs and like that. Those are the very obvious things.

The things we do not know about we will not really know about until we get into outer space, that have to do with what we find in outer space, new fuels, propulsion systems, the reaction and behavior of the human being. He may well be able to contribute to his own longevity.

These are the things that I am curious about.

The CHAIRMAN. Is it fair to say that, from a civilian aspect for the long pull, you think it is a matter of the greatest importance?

General GAVIN. No question about it.

The CHAIRMAN. Now, from a military aspect, what is your view as to the present satellite situation and the necessity of entering into it

and projecting our activities, pursuing our activities from the military angle?

General GAVIN. Of course, as I have said, it is the most significant thing of our time, militarily.

I feel rather strongly that it is a reconnaissance vehicle, first of all from the military point of view, and thus becomes part of an ICBM system. It is a reconnaissance vehicle that in time will be so refined and sophisticated in performance that it will be able to contribute such information of such an accurate and detailed nature that it in turn can be used as a target, acquisition target survey for an ICBM system.

If manned aircraft can no longer deliver firepower in combat they can no longer do reconnaissance

A satellite is, therefore, in my opinion, the reconnaissance element of an ICBM system in time.

The CHAIRMAN. Do you have some views on cosmic ray activity, too?

General GAVIN. Yes, sir. Of course, we want to understand the phenomena and the density and so on and we are getting data from Explorer on this now.

The CHAIRMAN. It is important to find out about meteorites and their effect on the satellites and space vehicles.

General GAVIN. Yes, sir, we are getting data on this, too. I believe that the Jet Propulsion Laboratory discovered the meteorite situation was not as bad as we thought it would be. Now an understanding of this will, of course, go right back into the problem of space travel itself because we will know the problems we have to deal with.

The CHAIRMAN. What about the transmission of the electromagnetic signals?

General GAVIN. You see, one of the great problems we have is defense against an ICBM, antimissile missile defense.

It is a very, very challenging problem.

Of course, we must acquire an object far out in space and track it accurately and the transmission of the image, let us say, of such an object through space goes through distortion and by being able to track a satellite physically, accurately track it, we are learning the first thing about tracking an object that will ultimately be and will probably be a missile warhead coming in, by using radards to reflect electromagnetic energy from that and receive the image of what we see through the ionosphere which distorts the image, depending on how you look through it, the angles at which you look through it.

By dealing with these problems, you learn the answers to the questions you have about the antimissile missile defense of the country.

So by participating in the space program and all the associated problems of control, tracking, and so on, you at once improve your defense readiness in the antimissile missile period.

The CHAIRMAN. Has there been any projection of consideration into electronic communications around the earth?

General GAVIN. Yes, this has been proposed. I know that it was in the paper released by the White House on 26 March.

Industry has proposed this and it appears quite sound. As you know, our surface communications problems on the earth are difficult. They are difficult to maintain. In fact, I remember reading a state-

ment to the effect that it would be simpler and easier to communicate with Mars rather than to communicate with Tokyo because in the former case we would have no atmospheric problems to contend with.

By putting satellites in a predictable orbit—you might have to control them after you get them out to get them exactly in the orbit you want—you can use these as vehicles to carry communications. They can play the communications back on being triggered, play them back automatically, and it would be possible to put a family of satellites in orbit that could fly over Tokyo, Washington, Paris, on schedule, picking up communications and playing them back.

From the viewpoint of industry, it will probably in the long run cost a lot less to communicate that way than it would be by maintaining very costly surface communications systems and requiring high energy to transmit, and so on.

The CHAIRMAN. We have had plenty of evidence about the known ability to send a family of satellites into orbit a considerable distance from the earth. Some testimony has been twenty-five or twenty-six thousand miles out.

General GAVIN. I really believe you refer to what is sometimes called a stationary orbit. That is putting a satellite in orbit at exactly the right distance so that it maintains a stationary position, vis-a-vis a point on the earth. This would mean launching it in orbit and adjusting it in orbit. There should be power aboard to enable it to kick itself a bit around and finally you get it at a place where you want it and then, as the earth rotates, it rotates with the earth.

By a satellite such as that located within range of Washington and another one within range of Moscow and another one within range of Tokyo, these could play back and forth to each other communications, television programs, or what not, and be merely relay stations completely encircling the earth.

The CHAIRMAN. It could be a worldwide communication network.

General GAVIN. Yes

The CHAIRMAN. Also a television network.

General GAVIN Yes, indeed. That appears possible.

The CHAIRMAN. Also, is there a proposal to launch a satellite that would give comprehensive photographic coverage of the earth?

General GAVIN. Yes, the reconnaissance satellite should do photography in time.

The CHAIRMAN. That is important?

General GAVIN. Absolutely.

The CHAIRMAN. You would have a pretty good coverage of the earth or any particular part of it?

General GAVIN. That is right

The CHAIRMAN. Within a comparatively short period of time?

General GAVIN. Yes.

The CHAIRMAN There are some, and I would like to ask you if it is your opinion, that believe if that were perfected it might make a marked contribution toward conditions that would prompt recalcitrant nations to enter into peaceful relations with other countries.

General GAVIN I would hope so. Those whom I have talked to feel that way about it.

The CHAIRMAN. Is it your opinion that the accomplishment of that would be a major contribution?

General GAVIN. Yes, sir.

The CHAIRMAN. And it could be done?

General GAVIN. Yes, sir, we believe it can be done.

The CHAIRMAN. Have you an opinion as to the period of time in which it could be put into practical operation?

General GAVIN. Yes, sir. I would say that if given adequate funding now we would be doing rather primitive photography in about a year and perhaps a year later doing accurate photography under good control conditions.

Mr. McDONOUGH. General Gavin, if we were capable of putting such equipment into orbit and the Russian Government knew that we were going to obtain this vital information from them, would we be involved in a military situation?

General GAVIN. Yes, we would.

Mr. McDONOUGH. How soon did you say that we would be capable of putting this kind of equipment into operation?

General GAVIN. I might say this problem is not a simple one at all. The satellite is perhaps the more simple of the two main sets of equipment, the ground and the space, the processing of these vast number of photographs on the ground, handling them and so on, would be a big thing, a very difficult problem.

If given adequate funding now, my estimate would be that by the end of the year or approximately within a few months we might be able to do some primitive photographic work and about a year later we would begin to show results that were somewhat sophisticated and we would refine it as we went along. Within 2 years we should be able to see reasonably good results.

Mr. McDONOUGH. If the Russians are far enough advanced at the present time, ahead of us, and are prepared to put such equipment into orbit, would we have any means of deterring them at the present time?

General GAVIN. No; none at all.

Mr. BROOKS. Would we have any right to deter Russia?

General GAVIN. Yes, sir, we would. Intrusion of our air space is something that we should decide is right or wrong.

Mr. BROOKS. That is not air space, that is space space.

General GAVIN. That is right. Intrusion of our space, we will say then.

Mr. McDONOUGH. We were discussing that the other day. Of course, if a manned aircraft came over the United States at 50,000 feet, we would attack it immediately, would we not?

General GAVIN. I would presume so; yes, sir.

Mr. McDONOUGH. Is that not the present mission of the aircraft, an unfriendly or reconnaissance plane?

General GAVIN. That is right.

Mr. McDONOUGH. If it came over at 100,000 feet, could we attack it today?

General GAVIN. Well, sir, very soon we will come very close to having that capability.

Mr. McDONOUGH. If it came in at 200,000 feet——

General GAVIN. No.

Mr. McDONOUGH. They would be invading, you think, our territorial rights?

General GAVIN. In my opinion, they certainly would.

Mr. McDONOUGH. Where do our territorial rights go to in elevation?

General GAVIN I do not know that you can give a definition such as height and elevation because soon you get out beyond the meaningful terms. Euclidean geometry says to have meaning after all and you get into something else.

It seems to me that if the act in itself is of potential harm to our Nation and endangers our security, then it is invading our territory.

Mr McDONOUGH Do you think that Sputnik No. 1 was harmful and invaded our territory?

General GAVIN Well, sir; I do not think so, but I am not sure about it either When we saw this coming last June and we knew that our satellite would not be up, this very problem came up for a great deal of technical discussion.

I asked my deputy to go down to talk to Dr. von Braun and General Medaris and see if we could not develop a satellite interceptor. I felt like the young man at Pearl Harbor who saw the Japanese airplanes coming and he called the attention of his superior to it and he was told, "We can pay no attention to it." We could see the Soviet satellite coming. It was on our scope practically. Yet we did not know what the threat to our Nation's survival would be. Possibly it could have been very dangerous We could have been confronted with a situation where active reconnaissance was taking place. We knew it. Nothing could be done about it. And all our pleas before the United Nations and everything else would gain no response at all.

So I asked my deputy to go down to Redstone Arsenal, which he did on June 21, and at that time Dr. von Braun came up with a proposal to meet our requirement. He said he would start on the program right away.

So, on October 4, I had lunch with Dr. von Braun and Dr. Shilling, which was the day that Sputnik went up. At that time I checked on our progress and we had some pretty solid thinking on it, we knew pretty well where we were going. We did it entirely on our own because (*a*), we were forbidden to launch a satellite; (*b*), we knew the Soviet was going to launch one; (*c*), we knew the country was in mortal danger, we had to do something So we started on a program of our own.

It has been a matter of concern to me at least since then. How far up is up, I do not know, but I know when our security is threatened we have to do something about it. When our survival is at stake you had better speak up and act.

Mr. McDONOUGH. Of course, we do not know whether Sputnik No. 1 was a reconnaissance satellite and we do not know what danger it was to us. However, whatever it was, they did not challenge our satellites when we shot them up. At least, they have not up to now. They have not contested the fact that we have sent up a satellite.

General GAVIN. No, sir, they have not. Of course, we have done everything possible to demonstrate that it is a purely scientific satellite as a contribution to IGY.

I might say before theirs went up we did not know it was going to be Sputnik 1 in size. If we had known that it would have been 1,184 pounds, which is what Sputnik 2 was, I would say we would have been quite concerned, because that is a big weight.

Mr. McDonough. Were we then capable of shooting a satellite into the air of 1,100 pounds?

General Gavin. No, sir.

Mr. McDonough. Are we today?

General Gavin. No, sir, we are not.

Mr. McDonough. What thrust does that require?

General Gavin. The thrust of that was estimated on the order of 280,000 pounds or so. So I would say, therefore, and I think the Atlas thrust, if finally mastered with all of the associated problems of control and so on, could give us that payload and a super-Jupiter could do likewise, I would not say "No," we could not do it. If you asked, could we tomorrow morning do it, I would say "No." I would say we are on the threshhold of achieving that thrust under good control, though.

Mr. McDonough. Up to the time you left the service, did you have any knowledge of what we can expect from Russia in their next satellite?

General Gavin. No, sir; I certainly do not.

Needless to say, it is a subject of considerable speculation. We should be concerned about it.

Mr. McDonough. And we have no means of determining through our electronic detection or other mechanical means what Sputnik 2 may have obtained in the way of reconnaissance of the United States?

General Gavin. I would suggest, sir, that Dr. Pickering and the people from the Jet Propulsion Laboratory answer questions on this subject. I have talked to them a great deal about it. We have received a great deal of data from Sputnik 2. A great deal of it is very mixed up and confusing and difficult to—not decipher but untangle, because you get a series of communications on one pass over and the next pass over you get a series again of different types of data, coded in a different manner. Then you get various permutations of these things. It was at the beginning. They may have it well in hand now

I would suggest that Jet Propulsion Laboratory answer your questions on this. They could still be getting data we know nothing about because it would only transmit to the Soviet Union and be silent over the remainder of the world.

Mr. McDonough. Thank you.

The Chairman. We have had a lot of testimony about the ability to reach the moon, hard and soft landings, but I will not go into that. What is your opinion about our ability to put something on the moon?

General Gavin I understand we have such a program finally approved now and we must go after it just as fast as we can.

The Chairman. Could you give us any idea when, if they go ahead in an effective way, that could be done?

General Gavin. I am not sure that I could put a number on it. Within a year, I would say, if we were allowed to go ahead we could go ahead with an object, a lunar probe shot, as it is called.

The Chairman. Would you say in the midsummer of 1958?

General Gavin. No, sir, I would not say that, not in the midsummer of 1958. We are practically approaching that now. If we had been given the green light last fall, we probably could have.

The Chairman. On the question of civilian-military control, you have some rather strong views, have you not?

General GAVIN. Well, sir, the civilian control is what I have supported.

The CHAIRMAN I ask this question of all witnesses, because it is a matter in which I am immediately, somehow or another, interested. I find myself recognizing the importance of things that might happen 2, 3, 4, 5 or 10 years from now. I do not like to get away from today and the immediate future.

Suppose another nation, a potential enemy of ours, had a decided advantage over us in the field of intercontinental ballistic missiles and at the same time had a good defense against our strategic air command, what position would we be in then?

General GAVIN Ours would be an exceedingly difficult position.

The CHAIRMAN. Is that beyond the realm of possibility?

General GAVIN. Not at all. It is entirely possible. I do not want to be facetious about that, but this is a subject that has been discussed very often.

In the very dynamic situation in which we find ourselves, and I referred earlier to the possibility of breakthrough from time to time, if one does not really stay on top of the situation and remain very curious and eager to make progress and keep doing things that must be done, we could well find ourselves in such a serious lag that you are being told what to do, you would be blackmailed. We would see rocket diplomacy and sputnik diplomacy extrapolated into some other kind of diplomacy.

The CHAIRMAN. I do not know of any witness that has disagreed with this or challenged it, that at least one country in the world appears to be ahead of us in the field of intercontinental ballistic missiles at the present time.

Have you an opinion on that?

General GAVIN. I think the Soviets are.

The CHAIRMAN And also in the field of intermediate ballistic missiles?

General GAVIN. Yes, I think so.

The CHAIRMAN. Have you any information that you could give us in a public hearing as to, first, if they are experimenting on a defense against our bombers and, secondly, the extent to which they might have progressed?

General GAVIN I cannot, except that they have demonstrated to us their surface to air missiles in the December 7 parade celebrating the Red Revolution last fall. The missile was rather impressive in its appearance, judging by its size, its configuration. It appears to be a good missile, surface to air.

The CHAIRMAN So we are not discussing a hypothetical question, necessarily?

General GAVIN Far from it.

Mr. BROOKS. Mr. Chairman, may I ask a question at this point?

The CHAIRMAN. Certainly.

Mr. BROOKS. You have referred a number of times to a breakthrough, General. Was not the breakthrough to which you referred an atomic breakthrough? You discussed that sometime prior to that, but was it not an atomic breakthrough that made the difference?

General GAVIN. Are you referring, sir, to the Redstone question raised by Mr. Ford a moment ago, what breakthrough was it that made it possible?

Mr. BROOKS. The development of the missile program is what I am referring to.

General GAVIN. This has applied particularly to some of the missiles of the future, breakthroughs in terms of size, yield, and achievement from a given amount of fission material. At the moment, though, my use of the word applies across the board.

One can never tell now when rather revolutionary things will be discovered quite suddenly. They can come in many forms ann many capabilities. It might be mobility, fire power, it might be i? unique forms of detection or control.

The breakthrough, as I use the word, applies to all of those.

Mr. BROOKS. It could be anything, any new scientific developmentp

General GAVIN. Yes, sir.

Mr. BROOKS. I would like to ask you this: Are we not getting into this sort of situation, that we will develop mechanically this missile and this satellite, but are we not going to be, and is not the controllin3 factor finally going to be, a biological factor?

General GAVIN. I do not know that I would say controlling, sir. Do you speak——

Mr. BROOKS. In manned missiles.

General GAVIN. Do you mean that the man will be the controlling factor always?

Mr. BROOKS. I mean the ability of a man to survive in space being a biological factor. Is that not going to finally be the controlling factor rather than the mechanical factor?

General GAVIN. Yes, sir, if I understand that, I would wholeheartedly agree with you.

I will put it this way: The man will remain the common denominator of any achievement we really make. If we are to make progress in the space program, man's adaptability to it and the ability to do something in it is the critical thing, yes.

Mr. BROOKS. Until we work out developments that will permit him to survive under these space conditions, is not the biological factor going to be the dominant one?

General GAVIN. I would not exclude achievement in space by the Soviets, let us say, as an entity of their overall military power. I would not exclude that as an achievement, that we should not worry about it simply because they have not learned to solve the biological problem, but in the long pull the biological problem absolutely must be solved because it must serve man and man must be part of the system. In the long pull, yes. But I would not overlook the possibility of serious laggardness on our part on unmanned space programs.

The CHAIRMAN. I just have one more question, myself.

How important do you consider it that we concentrate in an effective way on those activities that might be termed the "space program"?

General GAVIN. As now contemplated under this bill, where we concentrate the supervision—I have not read the wording of it—of the program under one agency, I think that is sufficient.

Where we have a decentralization of programs, a diversification of technological applications, such as will occur in the various services and the various laboratories, this is to be encouraged and sustained as it is going along, but we ultimately need one man responsible for the overall space program. I presume that he will be provided for in this legislation.

The CHAIRMAN Do you consider that it is so important that even the question of the survival of a nation or nations might be involved where some other nation had the advantage?

General GAVIN. Ultimately it could be put in those terms, yes.

The CHAIRMAN. I would like to get your viewpoint for the record as to how important you think, how vitally important you think it is for our country to prosecute known discoveries, and putting them into practical operation and pursuing further basic research for future discoveries?

General GAVIN. I would know of nothing of greater importance now than this

Mr. McDONOUGH. You are familiar with the tests that we are going to conduct on antimissile missile deterrents in the South Pacific, are you not?

General GAVIN. Yes, sir.

Mr. McDONOUGH. Is it classified?

General GAVIN. Yes; it is classified.

Mr. McDONOUGH. Then you agree with our decision not to cease the testing of nuclear weapons as requested by Russia recently?

General GAVIN. I agree with that entirely, sir. The problem, you see, is to live with it at home and to live with it you have to learn how to package it and package it in a useful way.

I think we are being very honest and straightforward in what we say, the American people are, and our Government is, and we should continue these tests and they will contribute unquestionably to the betterment of the lot of humanity.

The proposal to discontinue them, to me, is very, very high in propaganda value.

Mr. McDONOUGH Thank you

The CHAIRMAN. Mr. Feldman?

Mr. FELDMAN. I just have one question, General.

In considering the importance of the subject, would you say that the alternative is that we will either go to the stars or go to oblivion?

General GAVIN Yes, I would say so.

The CHAIRMAN. By the way, did you bring the charts with you?

General GAVIN. We have them in slides, sir, but the light is so poor in this room that we did not consider them worthwhile. The material has been covered verbally

The CHAIRMAN. We can have them in the record?

General GAVIN. We will provide them for the record.

The CHAIRMAN. Pardon me. I want an open executive session. I instructed the staff to send out a questionnaire to many distinguished persons throughout the country who will not appear before the committee. If the committee has no objections, the committee will support the direction given by the Chair.

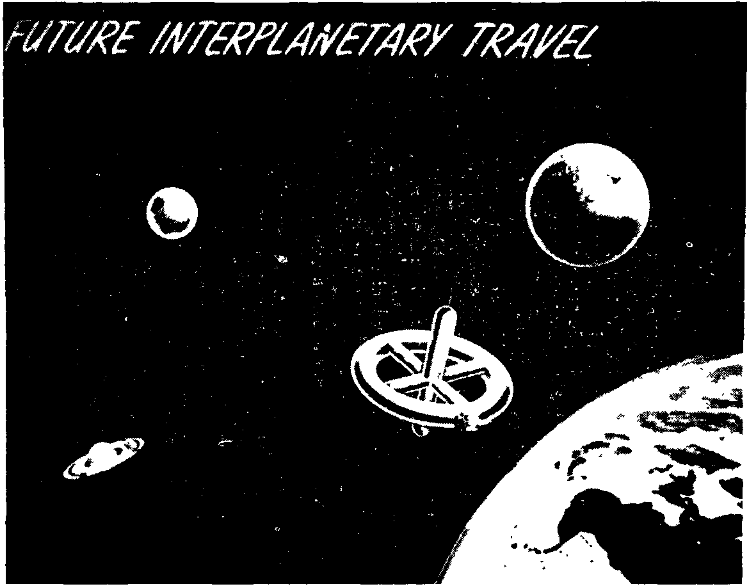
(There were no objections.)

That shows the confidence they have in me.

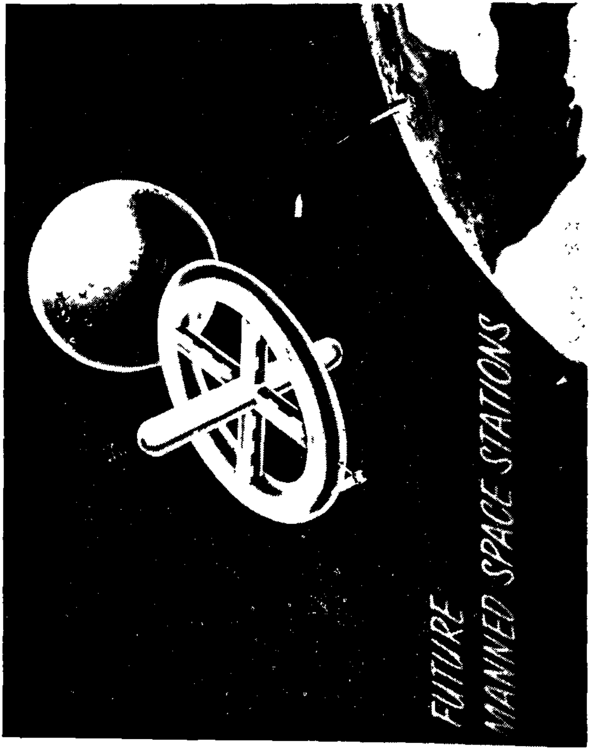
All right. Mr. Fulton.

Mr. FULTON. We have been talking rather easily about destroying or knocking down missiles and space vehicles that might be up there, but that raises a real problem. This is so because, where these vehicles are, there is no considerable air, but only space. So you cannot have an explosion in the ordinary sense.

(The charts follow:)



FUTURE INTERPLANETARY TRAVEL



FUTURE
MANNED SPACE STATIONS

METEOROLOGY

FUTURE COMMUNICATIONS NETWORK

What is the difference in trying to knock down such a vehicle and trying to knock down a plane? What would be used for explosives or what would the method of approach be? Would we have to run into the missile from the opposite direction it was orbiting or should we have a previous explosion of a sort of shrapnel and have those things go around the world and tear the missile apart as it orbits? Or, because there is no air, is it possible to put anything into space that would, in any way, destroy or block another missile?

General GAVIN. Sir, this has been given a great deal of thought. I think it is rather highly classified. I would strongly recommend that it be taken up in executive session.

Mr. FULTON. Then skip the method.

Is that not a problem?

General GAVIN. It is a very, very serious problem. At first we thought it was rather not too difficult, but we have more respect for it the longer we work with it.

Mr. FULTON. Actually, just reasoning from nonsecret material, you would pretty much have to have the equivalent of a hypergolic fuel as an explosive so that it had the means with it to explode, would you not?

General GAVIN. Yes.

Mr. FULTON. So that any kind of equipment that we might have to knock down another missile would have to have its own oxidation or hypergolic element in it to do its own functioning. This would mean double or triple weight, would it not?

General GAVIN. I would not want to be specific about that, but obviously it would have to get up there, it would have to be responsive to what it is told to do, to have a capability of doing something, moving.

Mr. FULTON. Let me ask you this, too. As a technical matter, on terms, what do you call a whole group of missiles or a squadron? Is it an array or is it a covey or is it a stable? Suppose you saw somebody with a whole group of missiles. What would you say it was?

General GAVIN. Do you mean, actually, just the missiles, not satellites?

Mr. FULTON. Anything. Suppose you saw all these missiles ready to go as we can at Cape Canaveral. What is that, is that a stable of missiles, stand, or brace?

General GAVIN. Ours is organized on the basis of a battalion of missiles or a battery of missiles.

Mr. FULTON. You would call it a battery of missiles, if you were speaking of a number of missiles?

General GAVIN. Yes, because to us a battery would have a certain number of missiles. In addition we would have a rate of fire. Using the standard terminology that the Army uses to refer to weapons and there is nothing particularly complex about it. To us, the missile in the Army has always been an extension of the field artillery art.

Mr. FULTON. Do you feel that the United States should enter into a race with any other country in the field of advancing military art into outer space?

General GAVIN. Sir, I do not think we should enter into a race. We ought to go on our own and let the people race with us.

Mr. FULTON. I am glad to hear you say that.

Finally, my feelings have been, and I was laughed at on the committee last year, that possibly the next major war in the world will take place in outer space and be without casualties, that it will be a system of counters, that we can tell when we are licked when they knock out enough of our satellites. Is that possible?

The next war, instead of being a holocaust, which everybody is predicting, to me may be a war without casualties at all, by merely having military counters which are then destroyed and leave the country open to attack and nobody makes the attack because it is too late.

I was on the cruiser "Boston" off Guantanamo Bay last year and saw a World War II fighter plane fighting two Terrier missiles. Nobody was up there, but they certainly had a pleasant fight one afternoon.

Now, is that not possible in the next war? Instead of thinking we are going to have men involved and casualties, possibly we are going to have a war without casualties, if it should occur, in outer space?

General GAVIN. That seems entirely possible.

Mr. FULTON. Thank you very much.

The CHAIRMAN. Any further questions?

Mr. FORD. General Gavin, I gathered the impression that the military relationship with the AEC has been very satisfactory.

General GAVIN. From my point of view, it certainly has.

Mr. FORD. Would you feel that in this space era a similar set-up of military and civilian would be a good arrangement?

General GAVIN. Yes, sir; including the congressional committees.

Mr. FORD. That is all.

The CHAIRMAN. Thank you very much, General. We appreciate very much your appearance. We know you made a sacrifice to be with us.

I am looking forward to you and your Mrs. and the family being permanent residents of Massachusetts. I am hoping that I will have the pleasure of seeing you frequently up there.

For the entire committee, I extend to you our sincere thanks.

General GAVIN. Thank you, sir.

The CHAIRMAN. Will you also ask Mrs. Gavin to forgive us for taking you away from her and the children.

General GAVIN. Sir; we are looking forward to being among your constituents.

The CHAIRMAN. I am hoping you will be one of my constituents

(Whereupon, at 4:25 p. m., the hearing was adjourned until 10 a. m., Friday, April 18, 1958.)

ASTRONAUTICS AND SPACE EXPLORATION

FRIDAY, APRIL 18, 1958

House of Representatives,
Select Committee on Astronautics and Space Exploration,
Washington, D. C.

The committee met, at 10: 05 a. m., pursuant to recess, in the Caucus Room, Old House Office Building, Hon. John W. McCormack, (chairman), presiding.

Present: Representatives McCormack, Brooks, O'Brien, Natcher, Sisk, McDonough, Fulton, and Keating.

Present also: George J. Feldman, director and chief counsel.

The Chairman. The committee will be in order.

We are honored in having as the first witness today the distinguished naval officer and American, Rear Admiral H. G. Rickover. We all know Admiral Rickover; it is unnecessary to refer to his broad experience, knowledge, and so forth.

We are glad to hear from you, Admiral. Do you have a prepared statement?

STATEMENT OF REAR ADM. HYMAN G. RICKOVER,[7] ASSISTANT CHIEF, BUREAU OF SHIPS, FOR NUCLEAR PROPULSION, DEPARTMENT OF THE NAVY

Admiral Rickover. No, sir; I do not have a prepared statement, but I do have one observation I would like to make, if I may.

The Chairman. Admiral, you go right ahead.

Admiral Rickover. I am not a candidate for the first trip to the moon, but I do have a number of suggestions of people I think should go on this trip.

That concludes my observation.

The Chairman. Is there some particular person you would like to see get up there?

Admiral Rickover. Yes, but I should discuss that in executive session. Perhaps your own list is even larger than mine.

Mr. Fulton. This is a one-way trip you have in mind, Admiral?

Admiral Rickover. Yes, sir; a one-way trip.

The Chairman. Admiral, you have read the provisions of the bill, have you?

Admiral Rickover. Yes, sir; I have read the provisions briefly.

The Chairman. And you are acquainted with the purposes of the establishment of this select committee?

---

[7] Rickover, Hyman George, naval officer, b 1900; s. Abraham and Rose Rickover; grad. U. S. Naval Acad., 1922; m. Ruth D. Masters, 1 son, Robert Commd. ensign, U. S. N., 1922, advanced through grades to rear admiral; qualified submariner, 1930; assigned to atomic submarine project with A E. C., Oak Ridge, Tenn., 1946–47, continues in development atomic submarine Bur. of Ships since 1947 Recipient Egleston Medal, Columbia Engring, Alumni Assn., 1955. Address care Bureau of Ships, Dept. of Navy, Washington.

Admiral RICKOVER. I am, sir.

The CHAIRMAN. And its duties and responsibilities?

Admiral RICKOVER. Yes, sir.

The CHAIRMAN. In the field in which the committee has to work we all know you have profound knowledge. Would you care to go ahead, Admiral, in your own way, and make a statement in connection with the hearings that are now being conducted, as to the importance of action being taken or the nonimportance, as you see it; what capabilities from a peacetime angle or a military angle the exploration of space—I use that descriptively—might produce; and the necessity for such an action, if any, on the part of our Government; your views as to the type of control, whether it should be civilian or military control—just where the division should be in the world of today? Cover the whole field.

That might just give you an idea.

Admiral RICKOVER. I will try to answer your question, Mr. McCormack. I would prefer if possible that I be asked individual questions rather than to talk in generalities. I could start with whether the organization should be under civilian or under military control. Would that be satisfactory, sir?

The CHAIRMAN. Yes.

Admiral RICKOVER. I definitely believe that the organization should be under civilian control. The Defense Establishment is already too large. If you let it keep on growing, soon it will be controlling the entire country. In fact, rather than putting new agencies in the Defense Establishment, I believe it would be very desirable for Congress to require the Defense Department to justify why it has as many agencies as it does.

One of the great difficulties in running the Defense Establishment is that it is so large. So I definitely would put the new agency under civilian control.

Now that is from an organization standpoint. From a scientific standpoint, I also believe that space is more a civilian than a military matter.

There is today a complete blurring of identity between military and civilian matters. War is now not a matter for the military alone. I am sure you are fully aware that the military is merely the cutting edge of the sword, that all of us, our farms, our factories, our schools, our Government—all of our institutions contribute to the military strength of the country.

For example, there are civilians in this room, and they pay taxes. If we did not have civilians to pay the taxes, we could not have the military. So you see even civilians are necessary to carry on war. And the Congress is necessary in order to pass laws and to furnish us money.

You could look at it this way: By the time intercontinental missiles are perfected it will be possible to hit any one part of the earth from any other part from a land base. Therefore, from the standpoint of being able to wreak destruction, it is not necessary to use space.

You might make an arbitrary distinction between the civilian and the military aspects of space by asserting that as long as a given military effect can be produced by missiles which are fired from the earth, to use space for that purpose would constitute an encroachment on its civilian uses.

With respect to getting into space, it is mostly a case of finding out about it and learning to travel and live in space. From that standpoint it is, in principle, no different than the airplane, which can be used for peaceful purposes or for warlike purposes. So from a philosophical standpoint I definitely believe that space should be under civilian control.

Furthermore, if we are ever to have peace in this tortured world of ours, we must make a beginning—we must get away from the purely military applications of space. We must recognize that the marriage of the military and science is proceeding too fully and too strongly; we must attempt to stop this tendency and instead emphasize the peaceful applications of science.

Have I stated my feelings about this?

The CHAIRMAN. You have stated your views on that subject very clearly.

Do you feel, with civilian control, that in the immediate days ahead there are military implications and these cannot be ignored?

Admiral RICKOVER. The military implications cannot be ignored; but we really do not know today what the military implications of space will be. We are not going to find out until we start investigating and doing research on the problems; only then will these implications become clear. As I mentioned before, sir, there is nothing we do today in the United States that does not have some military implication. When one claims that space has military implications, well, he can likewise claim that our farms have military implications, that our factories have military implications. When we focus on one aspect of a problem we tend to see it out of proportion and we do not realize that nearly everything we do today has military implications. On the basis of its having military implication the Department of Defense could take over everything in the United States, including the Congress.

The CHAIRMAN. The important factor in any agency that is established, whether civilian, or whatever the military does in connection therewith, or independently, is the type of man we put in charge.

Admiral RICKOVER. Yes, sir; the most important element in setting up any agency is the man you put in charge.

There are three aspects to the problem: One is the man you put in charge. The second is where the responsibility for the agency resides in Congress, and the third is where it is placed in the executive branch. But by far the most important aspect is the man in charge because, if he is a good man, it makes little difference what the organization is or where it resides in Congress. The latter two may hinder him to some extent but they will not stop him from doing a job.

But an ineffective man with a perfect organization and even with unlimited sums of money, will not be able to do this job well. The man is the most important factor.

In our country, because we tend to put so much faith in organization and in spending large sums of money to accomplish things, we frequently forget the importance of the individual.

You must always bear in mind that everything in this world is done by human beings or through human beings.

I would not be too concerned with the type of bill you pass, the type of organization you provide, if I were sure that the man placed in charge is a dedicated man who did not surround himself with self-seeking people, or with committees or boards composed of people

who are themselves self-seeking. I am sure you are aware of that. This to me is the important thing.

The CHAIRMAN. Have you an opinion to express as to whether any agency that might come out of these hearings and the Congress should be on a high level as far as power to make decisions is concerned and the authority to carry them out?

Admiral RICKOVER. The administration has recommended that the new agency be made part of the NACA, and I am sure that in making this recommendation the administration has weighed all factors and all considerations and considers this to be the best way of doing the job.

I do believe that the man in charge should be given full responsibility to make decisions, he should not be tied down by boards or advisers.

One of the comments I would like to make about the proposed bill—perhaps there is a later version of the bill than the one I have read—is about the Board of 17 advisers—that these advisers may recommend to the President who the Director of the agency should be, and that the Board shall meet four times a year. It seems to me that you are pretty much tying up the Director by such a board that meets occasionally.

Now the question whether to have a permanent group of people running the job or a group that comes in occasionally was thoroughly thrashed out in the hearings on the Atomic Energy Act in 1946. After extensive discussions with leaders from Government and from industry it was decided that there should be a full-time group, and this is why the Atomic Energy Commission today is composed of full-time Commissioners rather than a board that meets occasionally.

I do not consider it is good to have a large group of people who meet only rarely, and expect them to be effective in advising or running an agency. It would be better if the Director were nominated by the President and confirmed by the Senate. I do not think you should depend on any outside board to make such a recommendation or to be in the position of judging all of the actions of the Director.

The CHAIRMAN. Do you think that any agency should be headed by a commission or headed by a director?

Admiral RICKOVER. The agency should be headed by a director. This is provided for in the current draft of the legislation. I am merely addressing myself as to how he is appointed, how he is advised, and how he operates.

The CHAIRMAN. The reason I ask that question is because you referred to the five full-time Commissioners of the Atomic Energy Commission.

Admiral RICKOVER. Yes, sir. I do not say we should have five full-time commissioners for this new agency. I recommend there be one man, a director. If you do set up a joint congressional committee for this agency, the Director and his staff should report regularly to your committee. My experience in the Atomic Energy Commission has been that the Joint Congressional Committee on Atomic Energy is far more familiar with what goes on in atomic matters than are the advisory groups of the AEC. The congressional committee is not only more familiar with these problems, it is also far more effective. I believe the proposed congressional committee for the new agency could assume this same position.

The CHAIRMAN. Admiral, for the benefit of the members of the committee will you explore the possibilities of the utilization of outer space, first, in connection with peacetime purpose, second, military purposes, having in mind the military aspect of the present situation that confronts the world?

Admiral RICKOVER. A number of military witnesses, Mr. McCormack, who are far more qualified than I am to talk about the military aspects have testified to your committee. But as I see it, what we are doing now is attempting to learn more about the science of space. Our venture into space is a search for the truth, a search to find out about the laws of nature. I do not know what we are going to find, nor where this will lead us. There is absolutely no doubt that we will benefit from this work even though we cannot tell today what these benefits will be.

In any new scientific ventures we cannot tell at the time what is going to come out of them and we should approach them on that basis. We should not decide right now, today, that we are going to build large numbers of spaceships, that we are going to appropriate billions of dollars, that we should set up a huge agency. We should start this program in a modest way. We should give it enough money to do all the necessary research to start off with.

Now, research is not expensive.

Through constant discussion between the Director of the agency and the congressional committee a mutual decision can be reached as to how much to do and how far to go.

If you overburden this agency from the very beginning with a large number of matters, failure may result. I repeat: I would start the agency in a small way and with not too much money. If you start it with a lot of money, you will attract many people into it whose object really is to get in on the ground floor, and these will not necessarily be the proper people, and the work will suffer.

Do not forget, too much money can actually slow the work, because it takes time to spend money.

I see no need for a vast crash program, nor do I believe that the agency should immediately start to set up a large number of its own laboratories. There are many existing facilities in the United States that could be used. The agency should use all existing facilities, both governmental and industrial, to the maximum extent, before it creates new facilities. If we keep on permitting every agency in Government to set up all of its own facilities, pretty soon there will not be enough space left for cemeteries.

The CHAIRMAN. You have pretty strong views, based on your knowledge of the operation of the Atomic Energy Act, as to the part the Joint Committee of Congress plays therein. You have pretty strong views on the joint committee concept, have you not?

Admiral RICKOVER. Yes, sir.

I think the joint committee concept is a fine one and I believe if you were not guided so much by political considerations you would probably establish joint committees in Congress for most things.

The CHAIRMAN. I would not challenge that theoretically, but there are many practical difficulties, Admiral. You are absolutely correct, in my opinion, theoretically. We have joint committees in the Massachusetts Legislature and I am sure other legislative bodies do. But you then have many practical considerations which call for the

committee setup as we do have in the general rule of the committees of the House.

I personally would prefer the joint committee idea because it prevents the duplication of witnesses appearing, and is timesaving. I know all of that. But then there are other difficulties. If you are a member of 2, 3, or 4 committees and have 2, 3, or 4 meetings at the same time, it is pretty hard to be in all of them, and particularly in the Senate, with a body of 96 Members where each may be members of 3 and 4 committees. There are many practical difficulties.

Admiral RICKOVER. You have another practical political difficulty that most Members of the Congress want to be on the Appropriations Committees. You get around that partly by having 2 committees, 1 in the House and 1 in the Senate.

The CHAIRMAN. Of course, money is power.

Admiral RICKOVER. Yes, sir.

The CHAIRMAN. Theoretically, in my opinion, and I cannot speak for anyone else, you are absolutely correct. But there are many practical difficulties in having all committees joint. I am addressing this to a committee of this type.

Admiral RICKOVER. I defer to you as a politician, Mr. McCormack.

Mr. KEATING. We all do.

The CHAIRMAN. Would you say that the duties confronting this select committee and the special committee in the other body are more pressing now than those which confronted the select committee in connection with the Atomic Energy Act of 10 years or more ago? Not that that was not vitally important, but we had pretty much of a monopoly at that time, whereas as may not have today.

Admiral RICKOVER. I do not believe the problem facing your committee is as important as the one which faced Congress in 1945 when the May-Johnson Act was being considered. You were then faced with a problem where it appeared there could be utter and imminent destruction of the world from the uncontrolled use of atomic energy. I do not think the present problem is as urgent as that one was.

The CHAIRMAN. My question was not based on that point of view but from the idea of the necessity of this committee acting with promptness in making its recommendations. In those days we had pretty much a monopoly, based on the practical development that had taken place.

In other words, it is safe to say the Soviet Union is looking into this subject very seriously, too, from their angle.

Admiral RICKOVER. I agree that your committee should act with dispatch to get the agency started, but from the standpoint of the national danger, national urgency, your problem is not of the magnitude that confronted the Congress in 1945 in connection with the Atomic Energy Act, and for this reason:

The urgency for the space agency is said to come not from any civilian applications, but from military considerations.

Suppose a war were to break out today. We probably could not fight even that war with missiles, and yet missiles are much further advanced than any possible military weapons which might be used from space. We would have to depend to a great extent on protecting our country by SAC and by our naval striking forces. These are the only real deterrents we have today. We will have other deterrents in the future, such as Polaris submarines. But if a war broke out today, we

certainly are not in the position to defeat the Russians by the use of missiles. Missiles have not yet reached the operational stage except in the newspapers, and particularly around appropriations time. If this is so, then why do we have to think that space is so particularly urgent right now? The agency should be set up, definitely. It should be done with dispatch. But I do not believe that it is something that should have overriding priority today from a defense standpoint.

You must also be careful in considering this issue to recognize that each of the three services is trying to carve out a niche for itself in future scientific developments. They see the rapidity with which science is advancing, and each of them would like to seize onto something which is attractive and which offers potential so it can be used to bolster its own prerogatives and so help it in the struggle for appropriations.

This is a very natural thing, and typical of any vital organization. The military must not be blamed for this any more than other agencies of the Federal Government that try the same thing. Some of the urgency comes from the desire of each military service to establish beachheads in future scientific developments.

The CHAIRMAN. Mr. Brooks, do you have any questions?

Mr. BROOKS. Yes, I have a few.

Referring to your expression of "marriage of civilian and scientific forces" in sponsoring and developing new inventions in the scientific field, you therefore feel that such efforts should be civilian controlled. I agree with you. I think so, too. But we must all recognize—is it not true?—that the motives which enable us to get the money and to assemble the forces for these developments are largely from the military.

Admiral RICKOVER. Yes, sir; that is true.

But you are saying, "Here we are in Congress, and we are inadequate to decide measures on their own merit, and we also are using the excuse of military necessity to get money."

I agree with you that all you have to do is place a military connotation on anything and then add the words "Russian communism" to it and it has a lot of sex appeal. But if you want to do this job in a proper way—and that is your job as a Member of Congress, and I see you understand that point—why do you not stand up and, as a matter of principle, vote money for science and not necessarily have it tacked onto the military?

Mr. BROOKS. Well, you have a representative government; you have to be practical about it. I am not going to answer your question. I will let you answer it.

But there is no doubt that the money comes from military achievements rather than civilian developments; is that not right?

Admiral RICKOVER. Yes, sir.

Mr. BROOKS. I want to develop this thought in reference to the education of our scientists. You have had experience in dealing with our own scientists. Are you able to measure the grade, caliber, ability, and capability of our scientists in competition with foreign scientists?

Admiral RICKOVER. I think it is pretty well known, sir, that up to and through World War II we in this country were largely dependent on the scientific developments and on the brains of scientists from other countries. The figure which is generally used to estimate the scientific

excellence of a country is its proportion of Nobel Prize winners. We do not come out too well on such a basis.

Since the war there has been considerable improvement in the United States in developing our own brainpower, but unfortunately we have a built-in system of inferior primary and secondary public school education controlled by professional educators who are not scholars which prevents us from doing as well as the European countries in the development of scientific talents. These are the people who take hold of our youngsters in school and teach them that life is all happy, that all you have to do is to learn how to get along with people. They have charge of our youngsters at an immature age, from 6 to 18, and they teach them that they are going to be taken care of anyway, so there is no use striving to do anything hard because the important thing is to get along, to "adjust" themselves. And that pretty much ruins many of them.

This accounts for the fact that we do not have as many good scientists in proportion to population as European countries have.

I am sure you are aware, Mr. Brooks, that our college graduates have about as much knowledge as the secondary school graduates of Europe, and this is the situation which we must rectify.

In fact, I think it is the most important problem facing the country and the Congress.

Mr. Brooks. You are very pessimistic with reference to education, then, of scientists?

Admiral Rickover. Yes, sir, I am very pessimistic. I believe it is the most pressing problem that faces us, and I think if you were not too concerned about political repercussions, instead of having a committee of this kind you would probably organize a committee to investigate what goes on in education in this country and do something about it. I think it is already too late to prevent the Russians from getting ahead of us in education. But if we act rapidly now, if we act effectively, we may be able to redress this impending imbalance 10 to 15 years from now.

Mr. Brooks. Well, you surely would not suggest that the Federal Government take over education and dispossess what you call the professional educators from their jobs, would you?

Admiral Rickover. No, sir, I do not advocate the Federal Government getting into education. A good deal of money is being wasted on education by teaching the children a lot of frills, and by unnecessarily ornate school buildings.

What you could do in Congress is to permit scholars to set up a national standard for education so that parents could find out what their children should learn in school and be able to judge their children and judge the teachers. I would not force anything on the schools, I would make these standards permissible. I would also take control of our educational system away from the "union" of educationists.

Mr. Brooks. When you say "set up standards" what do you mean by that?

Admiral Rickover. As I have mentioned to you previously, sir, for about $50,000—and I know that you do not like to fool around with peanuts like that—for $50,000 you could find out what is being done in education in other industrial countries of the world. You could get an authoritative statement and not depend on the United

States Office of Education, which is controlled by the "union" of educationists.

You could find out what is being done elsewhere and then ask yourselves, "Are other countries doing more for their children than we do for ours?" You could say: "Here is a standard which we recommend to the people." That is about all you could do.

Mr. BROOKS. What would you do with your $50,000 if you go that amount?

Admiral RICKOVER. For the $50,000, I would have scholars analyze what is being taught in all advanced countries of the world, by age groups. I would then say: Here is what the children in Germany, France, or Sweden learn by the time they are 16 or 17; this is what they study; these are the kinds of examinations they must take when they leave high school; this is the ability that they require of their teachers. And instead of applauding when some educationists say we should teach our children to play with dolls——

Mr. BROOKS. So you would not exercise supervision, but you would let our own people know what is being done in other lands?

Admiral RICKOVER. That is right. I would let them know what is being done in other lands. I would exercise no supervision. I would say: "This is what we find is going on in other lands. This is what a 17-year-old knows in Western Europe. It is up to you to put pressure on your own school boards to see that our children are taught at least as much." This is what I would do.

Now, this can be done for $50,000. I hate to mention that sum because I understand Congress devotes about 1 minute for every $2 million appropriated, and I am taking up too much of your time.

Mr. BROOKS. Let me come down a little bit more to the fundamentals of these hearings here.

You feel that the emergency in the development of the space craft is not as great as the emergency in 1946 in the framing of legislation to handle the development of atomic energy?

Admiral RICKOVER. That is correct. I do not consider this emergency as great.

Mr. BROOKS. There has been a lot of testimony before this committee to the effect that the future domination, the future control of the world is tied up in the proper solution of this matter. What do you say about that?

Admiral RICKOVER. This may be true ultimately, but I do not think it is that urgent today.

Mr. BROOKS. You mean, it is not as quickly upon us as——

Admiral RICKOVER. As the possibility of destruction by atomic bombs was at that time. The very people who are telling you of this urgency are the same ones who are responsible for developing IRBMs and ICBMs. Now, then, this amounts to stating that they are going to have effective space weapons before they have missiles ready for war. It is not tantamount to that?

Mr. BROOKS. I rather agree on that, too, but you are not minimizing the importance of pushing forward at once with these developments, are you?

Admiral RICKOVER. No, sir. I firmly believe we should. I agree with the purposes of your special committee, I agree with setting up an agency, and I believe in getting on with the job just as fast

as possible. But I would not be stampeded into saying it is the most urgent thing in the United States.

Mr. BROOKS. Do you not think also that you would give them all the money that they could reasonably use on these projects?

Admiral RICKOVER. Yes, sir, I would do that. But you will find that in scientific ventures you do not need large sums of money to start off with. It is in the hardware stage that you need all the money. If you start in too soon with the hardware stage then you can waste a great deal of money.

Take my own case. When I started out I was only one person, and we gradually built up, added one person, then another. We started off with very small sums of money. I would let this agency prove itself and not set up a vast organization and start in going full blazes on everything. I do not think it is necessary or even desirable.

Mr. BROOKS. Do you feel that the NACA has proven itself already?

Admiral RICKOVER. The NACA has done a good job, sir.

Mr. BROOKS. And we should support it with adequate funds, do you not think, immediately?

Admiral RICKOVER. You are talking of the existing NACA?

Mr. BROOKS. Yes.

Admiral RICKOVER. Oh, yes.

Congress has been very generous not only with NACA but with all branches of the Federal Government. When the history of the past 40 or 50 years is written you will be known as the most generous people who ever inhabited this country.

Mr. BROOKS. This is a rather doubtful accomplishment.

Coming back, the Advance Research Project Agency is a brand new agency.

Admiral RICKOVER. But new research does not necessarily require large sums, sir.

Mr. BROOKS. What I mean is that the Advance Research Project Agency has not proven itself yet. This stipulation in the present bill would eliminate the Advance Research Project Agency, would it not?

Admiral RICKOVER. You mean in the Department of Defense?

Mr. BROOKS. Yes.

Admiral RICKOVER. I stated before, sir, that I believed that the major part of this job should be done by a civilian agency. I also stated that you might go even farther and find out what other things you can take out of the Department of Defense besides this.

Mr. BROOKS. The civilian agency you refer to would be the National Advisory Committee for Aeronautics, is that it?

Admiral RICKOVER. I was merely referring to the general idea of a civilian agency as opposed to a military agency. The administration has recommended it be combined with the NACA, and this is, of course, something for Congress to decide—whether you set it up as a completely separate civilian agency or whether you do it in the way the administration recommends.

Mr. BROOKS. In that agency, whether it be civilian or otherwise, you would certainly have the military represented?

Admiral RICKOVER. Yes, sir. No matter what the agency is, whether it is included within NACA, or whether you set up as a separate civilian agency, I would have the military represented somewhat in the way it is represented in the Atomic Energy Commission.

As you know, they have a Military Liaison Committee which meets with them regularly and sees to it that the interests of the military are taken care of.

When the Atomic Energy Act was being considered by Congress in 1946 there was much fear that a civilian agency would not adequately take care of military interests and requirements. That was the reason for the establishment of the Military Liaison Committee.

The fears of the military have turned out to be groundless. The Atomic Energy Commission has amply taken care of military requirements, and officials from the Department of Defense, both military and civilian, have frequently said so. In fact, the military have probably gotten more money for the development and manufacture of atomic weapons because of the existence of the civilian Atomic Energy Commission than they would have otherwise been able to—because the Atomic Energy Commission is a separate agency and uses its own efforts to augment the efforts of the Department of Defense.

In the case of weapons research and development I am certain we would not be so far advanced if we had left it entirely up to the military. The fact that the Atomic Energy Commission is a civilian organization makes it easier to obtain good scientists and engineers in its laboratories.

In the case of nuclear propulsion for naval vessels we definitely would not be anywhere as far advanced as we are today if it had been handled primarly in the Navy. We would not have gotten the necessary funds and the required degree of support. The Navy still supplies only a small portion of the money for research and development in this field.

So I say that anyone who fears that a civilian space agency will be detrimental to the military should find out how the Atomic Energy Commission has worked out. If I were responsible for space matters in the military and if I had no intent but to get the job done fast I would grab at the chance to have it assigned to a civilian agency.

Further, you must remember that once the Atomic Energy Commission finishes its research and development on a project it is turned over to the user—whether he is a civilian user or a military user. So I cannot see why there could be any objection by the military to a civilian space agency. In fact if they are smart they would be urging this on your committee.

Mr. Brooks. I helped write that legislation years ago.

Admiral Rickover. That was a very fine way to do it.

Mr. Brooks. But in this instance, would you have the Navy, for instance, represented?

Admiral Rickover. I would not have the services individually represented. I think you would be going contrary to the whole trend in the Defense Establishment. I would have the Department of Defense represented and let the Secretary of Defense decide for himself how he wants to do the job. I would not tie him down.

Mr. Brooks. You would support it with a military committee in liaison?

Admiral Rickover. Yes, sir. And not tie it down so it definitely has to be members from each service.

Mr. Brooks. I think it is vitally important that the military know what is going on there, so that they take advantage of developments.

Admiral RICKOVER. I agree with you. I want to be sure you understand me sir. I stated that I was for having the military actively represented, but I would not tie the Secretary of Defense down and force him to appoint a member from the Army, the Navy, the Air Force, and the Marines. Let him decide on how he gets his representation. This is the point I was making.

Mr. BROOKS. You mean, give him more latitude?

Admiral RICKOVER. Give him the latitude to decide on the representation he wants because, after all, you are holding him responsible, and if you hold him responsible you ought to let him do the job in his own way.

Mr. BROOKS. That is all, Mr. Chairman.

The CHAIRMAN. Mr. O'Brien.

Mr. O'BRIEN. Admiral, you touched briefly on your own experience and said you started with a small appropriation?

Admiral RICKOVER. Yes, sir.

Mr. O'BRIEN. I think we all know what a magnificent job you have done from such a small beginning, moneywise. I would like to ask this question, and I hope you will not think it is too abrupt or too pointed. But I have been disturbed by suggestions in testimony that people are given a job to do, they do a good job, and then suddenly there is a change. There is not the continuity that there should be, which leads up to this question:

Are you assured of being retained in the Navy during the next few years to finish building a nuclear Navy?

Admiral RICKOVER. Do you want an answer that is equally as abrupt as your abrupt question?

Mr. O'BRIEN. I would be delighted; yes, sir.

Admiral RICKOVER. The answer is "No, I am not assured."

Mr. O'BRIEN. You have no assurance whatsoever?

Admiral RICKOVER. No, sir.

Mr. O'BRIEN. I would like to ask you this question, and I think it ties in with what you have said so far:

It is not true that one of our weaknesses in this country has been too much reliance upon what we call mass production? We get a certain conventional weapon, we will say, and we can outproduce any nation. But we are now entering a field where mass production is not the answer. Is that correct, Admiral?

Admiral RICKOVER. That is correct.

There is a great degree of obsolescence of equipment, a greater degree than there ever has been, and, of course, that degree of obsolescence is increasing all the time. This, of course, is where the money is spent. Large sums of money are not spent in research and development; the big money is spent in production.

On the other hand you have industry that gets geared up to do a job, and they like to turn out tanks and planes just as fast as cigarettes. It is pretty difficult, once you start on assembly line operating, to shut it off. And this is the great danger—forces build up to keep the production lines rolling, even when the equipment being turned out may be obsolescent.

You are stating the matter in a somewhat different way than I did, but we are thinking about the same thing. I would spend all the money that is necessary on research and development because, as we

well know, the amount of money we spend that way is relatively insignificant. But I would stop compounded duplication between the services in the manufacture of production items. This is where a considerable amount of money gets spent.

Of course, the larger the Defense Establishment becomes, the more connections it has with industrial and scientific and educational organizations, and the more pressures are exerted on it. It is an ever-growing spiral. This is what I meant by the Defense Establishment being too large.

If Congress really wants to save money, it is going to have to cut down the size of the Defense Establishment, it is going to have to see to it that everything that can possibly be done by the civilian economy is done by that economy and not by the Defense Establishment.

Another aspect of this is to the one of management. The people who run the military are the operators. I will confine myself to the Navy because I know more about it than I do about the other services. Officers who are used to command at sea come to Washington for short periods of time. They are given positions where they control technical decisions. Now, I maintain that only people who have some technical qualifications should be in positions where they make technical decisions. A great deal of money is wasted when wrong decisions are made by people in military authority, whose subordinates have been trained or have learned to obey military authority, and so will not always say what they really think. Scientific and technical matters cannot be solved by military orders. Nature knows no rank.

I am sure that we could get our prototype atomic energy ships, the nuclear ships, built faster if they were not in the military. If I had been able to build the *Nautilus* entirely in the AEC, I could have done that job faster.

Actually, what I wanted for the *Nautilus* was eventually done anyway, as it has been for the other nuclear ship prototypes. But much of my time has been spent fighting off people who come in just like on a transmission line every 2 or 3 years and who have to be educated. Then when the are educated, off they go and some other officer comes up on the transmission line.

Is that a good speech?

Mr. O'BRIEN. That was very good.

Admiral, we have heard the phrase "leapfrog."

Admiral RICKOVER. Yes.

Mr. O'BRIEN. It has been used a lot.

Admiral RICKOVER. Yes.

Mr. O'BRIEN. Is it not a fact that is what the Russians did to us? We were just assuming they were catching up in the nuclear field and they had the research scientists actually working ahead, and they suddenly unveiled these accomplishments?

Admiral RICKOVER. May I answer that in a broader way, sir? The Russians, as you well know, have a plan for world domination, and they have been working on that plan for the past 30 years. There are changes in government, there are changes in methods, but they resolutely go ahead toward that same goal.

We have no such national plan. We have prided ourselves on being democratic. Some take that term to mean that anyone can do anything he wishes. Now there are limits even to democracy, because if

you let everyone do anything he wishes, he will ultimately destroy himself and the Nation as well.

I do not mean by that that we should have military control. You can tell from the tenor of my remarks that I do not believe that. But the Russians have done two things which, in my opinion, are outstanding.

One, they have recognized that in this modern scientific age they must train people technically and scientifically, and they have done an outstanding job. As an example, they are graduating more astronomers from one university in Russia than we graduate throughout the entire United States. They are graduating 5 to 6 times as many metallurgists as we are. Metallurgists and astronomers are the very people we need for the space program, but we do not have enough of them. This, the Russians have accomplished by offering additional incentives to study astronomy and metallurgy.

We have deluded ourselves into believing that a man must live in a democratic atmosphere, in an atmosphere of freedom, to be a good scientist or a good engineer. But this is not necessarily so. We see evidence of the work of the Russian scientists and engineers, yet we still refuse to believe that they are capable. The reason, I suppose, is that it takes human beings too long, much too long, there is too much inertia in our thinking, to change fast enough.

To give you a minor example which illustrates that freedom is not necessary for scientific work, there is the famous case of the biologist in Nazi Germany. He was asked why did he not get out of Germany while there still was time, and he said, "The Nazi Party gives me all the guppies I need to experiment with." And the ability to obtain these guppies—these are the little fish you buy in the 10-cent store—was more important to him than to leave Germany and live in freedom.

The other thing the Russians have done besides vastly improving their education—is to reduce their lead time. They have learned how to cut lead time on important military items to roughly one-half of ours.

By lead time I mean the time from inception of an idea until the finished item is rolling off the assembly line, ready for use. And they have done it in a very simple way.

They have put a man in charge of a project and said, "Joe, you do this or else." And they do not bother him while he is doing the job, provided he produces.

But what do we do: First, we never put anyone in charge. I defy you to find anyone in the Federal Government that has any final responsibility for anything, a clear-cut responsibility. I know that Members of Congress have tried for many years to find such an individual, but you cannot locate him. Certainly not in Washington.

How can you possibly have real responsibility, particularly in the military where the people keep on changing all the time? So if something goes wrong, the man occupying the desk at the time can say, "Well, the man that was here before me started it—he is responsible." And the man who started it can say "I left the job before it was finished, so I'm not responsible." This freedom from responsibility is a marvelous invention.

So we in the military have a "union," too. This is our union—that we are not around long enough to be responsible for anything. You

must have responsibility if you are going to get a job done. And once you give a man responsibility you have got to see to it he is not bothered too much by the pure administrators who are always making sure that the many minor rules and regulations are carried out exactly. Just like the requirement every month to collect for personal local telephone calls. You could say, "Well, I will get busy and write a letter to somebody to stop this foolishness," but it takes too much time, so you pay 10 cents every month. It is that sort of thing.

Mr. O'Brien. Thank you very much.

Admiral Rickover. Have I answered it?

Mr. O'Brien. You certainly have. I appreciate it.

The Chairman. Admiral, you have under your direction two major laboratories now?

Admiral Rickover. Yes, sir. I have the Bettis Laboratory of the Atomic Energy Commission in Pittsburgh which the Westinghouse Co. operates for the Atomic Energy Commission, and the Knolls Atomic Power Laboratory at Schenectady, N. Y., which also belongs to the Commission and is operated for them, by General Electric Co. There is also the Windsor, Conn., Laboratory of Combustion Engineering, Inc., which is working on a submarine plant for us.

The Chairman. What do you do for the Navy?

Admiral Rickover. What do I do for the Navy?

The Chairman. Yes.

Admiral Rickover. Well, I draw my pay from the Navy.

The Chairman. I was not asking from that angle, Admiral. I wanted to get a picture for the record.

Admiral Rickover. I have dual duties, sir. My primary duty is my assignment by the Secretary of the Navy to the Atomic Energy Commission. In that capacity I am responsible to the Commission for the design and development of nuclear reactors for the propulsion of naval vessels.

In the Navy Department I am Assistant Chief of the Bureau of Ships for Nuclear Propulsion. My job is the design and installation of nuclear propulsion plants in naval vessels.

For the first one of a new type nuclear propulsion plant, I am responsible for the complete propulsion plant from the reactor right through to the propeller. For follow ships, that is, for the second and subsequent ships, I am responsible for the reactor plant.

I am also responsible for the design, development, installation, and procurement of all the materials that go into these plants and for setting up and training the industrial organizations that make them, for training the shipyards in nuclear ship applications, for training the crews of our nuclear naval vessels, for seeing to it that what Congress wants us to do is done, for using competitive bidding, and so on. Does that answer it?

The Chairman. Well, yes. I wanted to get into the record what broad jurisdiction and responsibility you have. You have both peaceful and military objectives?

Admiral Rickover. Yes, sir. I am also responsible for the Shippingport atomic power plant. This is the first large-scale central station atomic power plant built in this country. It delivers 60,000 kw. of electrical power. It is generating electrical power for the city of Pittsburgh right now.

The CHAIRMAN. That is for peacetime services, as I remember.

Admiral RICKOVER. Yes, sir; however a reactor does not know the differences—whether it is supplying electricity for a naval vessel or for civilian use. There is not much difference; the same design principles apply to both. What is used in one is adaptable to the other.

The CHAIRMAN. How many assistants and help—I put the word "help" not in the sense ordinarily used—are under your jurisdiction?

Admiral RICKOVER. I have about 100 scientific and technical people at headquarters. You do not need many people, because if you build up to much of a staff then your time is taken up with them—stenographers start in crying and all that. You do not want a lot of people around, you want just a few people: you use as many outside organizations and people as you can.

The CHAIRMAN. When you use outside organizations and they make any discoveries or advances does the Government get the benefit?

Admiral RICKOVER. In accordance with the Atomic Energy Act, any inventions or discoveries that are made ipso facto belong to the Government because it is all being done with Government money—I believe the revision of the Atomic Energy Act in 1954 tends to modify that to some extent.

I strongly urge that in this bill you make it mandatory that anything that is discovered belongs to the United States Government, and for this reason: If you do not do so, you will start a fight between the advocates of public control and private control.

I would hate to see developed a private versus public fight for ownership of the air. I would definitely prevent that. I would provide in this act, since all of the research and development is to be done with Government money and to discourage industrial organizations from trying to encroach on it, that the air belongs to the people of the country, because it is the people's taxes that will pay for the development of space.

If you state this clearly in the law, you may stop some of the difficulties that have arisen in the atomic energy game. If you recognize this now, if you have somebody on your staff get into this problem and make it very specific that these developments belong to the people of the country and not to anyone else, that should prevent some difficulties.

The CHAIRMAN. Admiral, you will have the opportunity, as other witnesses, to edit your testimony.

Admiral RICKOVER. Not after the newspapers get hold of it.

The CHAIRMAN. I know if we did not have the newspapers we would be in very bad shape. I know you will agree with me on that.

Admiral RICKOVER. Yes, I do.

The CHAIRMAN. We all have our bones to pick with them occasionally.

Admiral RICKOVER. Yes, sir. It is very fortunate that we have them to watch what we in the executive branch do and what the committees in Congress are doing.

The CHAIRMAN. In your editing you can elaborate on any of your testimony, and particularly in connection with, but not confining it to, your last observation about the possible improvements that we could make in this over the Atomic Energy Act in the light of their experience, and they were pioneering.

Admiral RICKOVER. Yes, sir.

The CHAIRMAN. I would like to have you elaborate on that as to what suggestions you think could be made.

Admiral RICKOVER. Yes, sir.

The CHAIRMAN. As to the work done in the committee, and we all will read these hearings many times.

(The elaboration above suggested is as follows:)

UNITED STATES ATOMIC ENERGY COMMISSION,
Washington, D. C., May 7, 1958.

Hon. JOHN W. McCORMACK,
Chairman, Select Committee on Astronautics and Space Exploration, House of Representatives.

DEAR MR. McCORMACK: At the time of my testimony on April 18, 1958, before your committee you asked that I submit comments for the record on patent provisions for outer space legislation.

Of course I lack the expertness to recommend specific legislative language, but I would like to make some general observations. I believe that one can distinguish clearly between patent rights arising from discoveries made with the expenditure of public money and those which are developed privately. In the case of inventions conceived during the course of a Government contract or similar relationship, strong provision should be made for the patent rights to be vested in the Government. A provision such as this does not freeze patents because the Government has continuously licensed others to use such patents in the interest of the country as a whole

Whenever a private party conceives of an invention or discovery and no Federal funds are involved in the work, he has a rather sacred constitutional right to the exclusive use of his invention or discovery. I do not think that writing a provision in outer space legislation which would award the Government title to patents developed with the use of Government funds would, in any way, infringe upon this right.

Perhaps some may think that this oversimplifies the matter but I have long felt that the patent provisions of the many laws surrounding Government research work could be simplified to a greater extent.

I do feel strongly that no provision of the law setting up the space agency should ever be construed to confer on any individual a right which could in any way impede or restrict the use of relevant technology by our Government for domestic or for international purposes. An unequivocal statement to this effect in the law would be an earnest of our intention to help other nations.

I hope these comments are of help to you.

Sincerely yours,

H. G. RICKOVER,
Rear Admiral, United States Navy.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. Admiral, one of the main duties of this committee is to make the necessary recommendations providing for research into problems outside of the earth's atmosphere.

Going back to this question of urgency, I understand you are of the opinion that a crash program is not necessary at the present time, and that this program is not urgent enough to demand appropriations of large sums of money. Am I correct in that?

Admiral RICKOVER. Yes, sir.

Mr. NATCHER. You mentioned the sum of $50,000 as a starting amount.

Admiral RICKOVER. No, sir; no. I was talking about another subject.

Mr. NATCHER. Education?

Admiral RICKOVER. Mr. Brooks and I had previously discussed the establishment of standards for public-school education. The $50,000 was for that purpose.

Mr. NATCHER. That pertains only to education?

Admiral RICKOVER. That pertains only to education.

Mr. NATCHER. Admiral, what suggestions would you have as far as appropriations are concerned in this particular field as to amounts? Should the amount be large or small?

Admiral RICKOVER. I cannot answer that question specifically, sir. I do know this: that research does not take a large sum of money. It is the production of hardware that does.

The CHAIRMAN. You are talking about basic research?

Admiral RICKOVER. Yes, sir. Even a lot of applied research does not cost too much.

The point was made before about not rushing into the manufacture of large quantities of hardware items, because today everything becomes obsolescent so quickly. Research is not going to cost too much money.

The principle I was trying to establish was: Don't start off with a big full-blown organization, staffed with all sorts of people, with a big public-relations staff, and all that. Start it off in a small way and let it build up. Let the agency have faith and confidence in the committee you are going to appoint, that they can come to the committee with their problems and that they will get quick action. Make it flexible. Do not just say, "Here is a lot of money to spend."

Has it not been your experience that whenever you appropriate large sums of money it is always spent?

Mr. NATCHER. Admiral, I am a member of the Committee on Appropriations, and the statement that you made concerning appropriating large sums of money, and apparently small sums, certainly does not apply to two of my good friends, my Chairman, Mr. Cannon, and Mr. Taber. They are two of the members of the committee that believe in holding appropriations down, and we also have other members on that committee that do, also, Admiral.

Admiral RICKOVER. Yes, sir; but you also have a lot of experts coming to you and telling you that unless you appropriate the last penny they ask for the country is going to fall. Then you do not know what to do.

Mr. NATCHER. Admiral, you are not one of those persons that believes that Russia should place in orbit 48 satellites that will every hour and 15 minutes drop a note on the steps of every capitol of every State in the United States informing the people there as to weather conditions, and then say, "Well, we are a little behind"?

Admiral RICKOVER. No, sir.

Mr. NATCHER. You believe as far as our satellite program and our general missile program is concerned that we should have ample appropriations at the present time, do you not?

Admiral RICKOVER. Let me put it this way, sir:

From a defense standpoint I believe that we will have effective missiles which we could use for returning an attack by the Russians before we will have effective means of retaliation or attacking the Russians by means of space weapons.

Does that state my opinion of it?

Mr. NATCHER. Yes, sir.

One of our greatest achievements of modern day government, you will agree, was placing in action our nuclear submarine, and you are to be commended on the fine part you played in that program. Now, comparing that particular project with the project we have under

consideration here, Admiral, how does it compare from the standpoint of the starting days? Did you have the necessary interchange of knowledge as far as our allies were concerned?

Admiral RICKOVER. There was no knowledge available to be exchanged at that time in that particular field. But what I did have was this, which is more important than getting access to knowledge: I surrounded myself with 7 or 8 people who were smarter than I was. This is the sole criteria I use at all times for hiring people. I will not hire anybody that is not smarter than I am.

Then we had access to all the knowledge that was available in the Atomic Energy Commission and elsewhere in the United States. People did not come to us bearing this knowledge on silver platters; we had to go out and find it for ourselves. This is getting to be a rather uncommon thing now.

Apparently the way to lick all problems today is to go to Congress, get large appropriations, and depend on trained scientists waiting to be hired to come and work for you. Life is just not like that. It is not that way in science, it is not that way in the military, and it is not even that way in politics.

I know what Congressmen have to do to get elected: You have to struggle and you have to scratch. When a man wants to do a job in science he also has to scratch.

Mr. NATCHER. Admiral, from time to time we hear statements to the effect in this country we are not pooling our scientific knowledge with our allies, we are not deriving the benefits that we should receive as a result of this pooling of knowledge.

Admiral RICKOVER. That is correct.

Mr. NATCHER. You feel we are deficient as far as that phase of the program is concerned?

Admiral RICKOVER. I definitely do. To have a true entente, a true working together with the Western European countries we should exchange all manner of information with them. It is very foolish of us not to do that.

Mr. NATCHER. Admiral, in your opinion does science deserve a place in the Cabinet at the present time?

Admiral RICKOVER. Well, that is a hard one. Does science deserve a place?

I do not know that I can answer that question. The question arises because scientists are more vocal and articulate than a lot of other people—you hear more from them. But I would rather trust my destiny to a committee of Congress than I would to a committee of scientists.

Does that answer your question?

Mr. NATCHER. That answers it, Admiral, and I want you to know that I am inclined to agree with you.

Thank you, Mr. Chairman.

Mr. FULTON. We all agree.

Admiral RICKOVER. I am sure you agree because I am saying a nice thing about you.

The CHAIRMAN. But we have to rely on testimony from gentlemen like you and others in your field and in the scientific field, which sort of lets us apply what little commonsense we have.

Admiral RICKOVER. Well, you have to recognize what the scientist really is. He is a man who is interested in learning new things, in

developing a new formula. But unfortunately he is generally so engrossed in that formula, that when he evolves it he thinks the whole problem is licked, and he wants to go on to evolve another formula. But what he has actally done with his formula is to donate a legacy of terrifically hard, painful problems to the engineers which will take up their time for many years. I have to take that scientific formula or concept and try to translate it into a workable and reliable piece of hardware.

When a scientist makes a mistake, he takes an eraser and erases it; but when an engineer makes a mistake, he has to wear it around his neck where everyone can see it. That is the difference.

The CHAIRMAN. I am not going to get into that broad discussion now.

Admiral RICKOVER. By this time you should have many scientific qualities, having heard so many scientists.

The CHAIRMAN. You are unnecessarily generous.

Mr. Sisk.

Mr. SISK. Admiral Rickover, I would like to read one sentence here and ask if you agree with it.

> One of the most frustrating problems concerning American current activities in space projects is what arises in connection with the difficulty of pinning down responsibility for progress or lack of progress.

Do you agree with that?

Admiral RICKOVER. I definitely do, but that applies to any field, not only to the space field. It applies to the grocery field, too.

Mr. SISK. Do you feel that the bill which we have before us, in any event, will solve that situation with reference to space?

Admiral RICKOVER. I am trying to be impartial.

Mr. SISK. I refer to the matter of pinning down responsibility. We are talking here about space now.

Admiral RICKOVER. No, sir, it does not touch on that at all.

Mr. SISK. The bill which we have before us does not touch on that?

Admiral RICKOVER. Any more than any other bill that you have passed assigning functions to agencies of Government. This bill is no different from the others; I do not see where Congress has been very effective in getting responsibility to be assumed in other fields. Why do you then think that in space, which we know so little about, you will all of a sudden get people to accept responsibility?

Mr. SISK. All right. Let me ask you this:

Do you have a suggestion or recommendation to make to this committee? We were given a responsibility to come up with something in order to pin down responsibility. What is your recommendation?

Admiral RICKOVER. I have tried to hint at solutions.

I would say this: One of the reasons I recommended against military control, is because the military man is changed too often. I said you could not get adequate responsibility where the man did not stay around long enough—where there was a constant change of personnel. I do not know whether you were here when I made that statement.

For the civilian space agency you have the same problem.

This is what I would do if I were on the Appropriations Committee: If a man came up and asked for an appropriation for a certain project, I would say, "Whose idea is it? How far is it along? Who is going to be responsible? Is he going to stay on his job for the

duration of the project? When will it be finished? Will it really be operational or will it still require several years of testing? Will you report to us each year how close you are to meeting your original schedule, and why you are behind? How much will it cost? Will you personally take responsibility? And what do we do to you if you don't succeed?"

Try that and you may get a reduction in requests for appropriations.

The CHAIRMAN. Admiral, on the question of men not being around long enough, that could be taken care of in the Defense Department, could it not?

Admiral RICKOVER. Oh, yes.

The CHAIRMAN. We have known this for years. That is not anything new. I was on a subcommittee that looked into that in 1945, the Riehlman subcommittee.

Admiral RICKOVER. On research and development. I remember that.

The CHAIRMAN. As a matter of fact, I had a very important part in bringing that subcommittee about.

Admiral RICKOVER. You had an important part in getting the report printed, yes, but I think that is where it stopped.

The CHAIRMAN. I sat in on all the hearings.

Admiral RICKOVER. I have read the record.

The CHAIRMAN. Those are human qualities. In no matter what walk of life you are bound to meet them. But the question is to try and reconcile them, and I remember we recommended very strongly the establishment of a corps within the departments where young men or officers could devote their whole life to the field of research and technology, and again with the opportunity of advancement. That is a human trait.

If I were in the Army today or the Marine Corps or the Air Force, I would like to go ahead if I were making it a career. That is human. I could see where men would want to get into some branch where the opportunity for advancement was more rapid. Again, it is a human trait.

So that could be taken care of within the Defense Department, could it not?

Admiral RICKOVER. Yes, sir, it could.

The CHAIRMAN. We cannot do everything by legislation. We could, but we should not drive it down their throats.

Admiral RICKOVER. You cannot drive it down their throats. But if the chairman of the Appropriations Committee says something to a Government agency, they listen. You are listened to more than you realize.

The CHAIRMAN. Suppose the chairman of any committee, without appropriations, might be wrong.

Admiral RICKOVER. Why should you be any more wrong than a bureaucrat?

The CHAIRMAN. I cannot answer that question. I have accepted that we are all human beings and it is human to err.

Admiral RICKOVER. You tell me you sat through many days of hearings, and I happen to have read every word of the Riehlman committee report. The committee put a great deal of effort into it

and it was a fine piece of work. You finished that job and then were not interested enough to put those recommendations into effect. That is where I indict you.

The CHAIRMAN. Of course, the putting into effect was 95 percent administrative. Under the law they had the power to do it within the Defense Department.

Admiral RICKOVER. But the Defense Establishment does not want to do a thing of that sort because they are still going along with some outmoded theories on how to prepare for modern warfare.

The CHAIRMAN. Without going into all that—because I see you and I basically agree—the power and the authority rest within the Defense Department to meet that particular situation.

Admiral RICKOVER. Yes, it does, and this is one of the reasons why the Secretary of Defense wants to get some more authority. I believe he wants to put some of these things into effect.

The CHAIRMAN. I have some views on that, but I do not want to get too far into that now because that is going to be one of the battles of the generation, I would imagine, from what I see in the newspapers.

Mr. Sisk.

Mr. SISK. Admiral, would you make some specific recommendations to improve this bill in order to pinpoint the responsibilities which you think so necessary, and which I agree with you are necessary?

Admiral RICKOVER. I mentioned previously the 17-man board of directors that meets 4 times a year. Of course, any suggestion that I make would require a great deal of study on your part. You might inquire about the efficacy of various boards of this kind in Government agencies, how effective they really are, whether they are merely figureheads, and whether logrolling occurs with these groups, and so on.

Mr. SISK. Let me ask you this, Admiral.

As I understand, one of your criticisms is the fact that people change and no one knows today whether he is going to be here tomorrow and cannot carry out the job in many instances.

Admiral RICKOVER. Yes, sir.

Mr. SISK. Let me ask you this:

If we provided in this bill a director and granted him the power and authority to assume the responsibility and set his term at 20 years or 30 years by law, where he could not be removed except for the normal things that would cause impeachment, such as the actual violation of law—something of that kind—would that in any sense tend to help?

Admiral RICKOVER. I do not agree with so long a term for a job of this kind. The normal tour in a commission is about 5 years. I think that is adequate. The man appointed to head an agency should come up for confirmation by Congress periodically, otherwise you can get a man in for 15 years who is doing a poor job, and you have no way of getting rid of him.

Put the man in for a 5-year term, and especially where you have a special congressional committee you can amply judge whether he is doing a good job.

This new agency is a good example where the Senate should really exercise its constitutional duties of advising and consenting. The

Senate does not do this effectively in many cases because it just does not have the time to. I am sure you are familiar with that.

But in the case of important appointments, and where there are interested congressional committees, the committee might, by a special rule set up by Congress, have the opportunity to advise the Senate whether the man is doing a good job or not.

Mr. SISK. I appreciate the statement, and I agree with that. I personally would not favor 20 years. I was just trying to find some way of overcoming your particular objection to the fact, as I understood a while ago in your discussion with some of the other gentlemen here, that we had changes too often.

Admiral RICKOVER. May I discuss this a little more?

Mr. SISK. Yes.

Admiral RICKOVER. If you could keep this field out of politics and away from other pressures, you will do good. But the tendency, as I have seen it, is that pretty soon you start getting pressures of one kind or another; they may even be political, they may be from universities, they are not always industrial.

The CHAIRMAN. They might be friendships.

Admiral RICKOVER. Yes. As a matter of fact, friendship has been known to influence politics also, Mr. McCormack.

The CHAIRMAN. True. But I simply am trying to elaborate a little. It is not necessarily confined to the field of politics. Friendship could influence——

Admiral RICKOVER. Friendship does influence it, sir. But I have found out, if a man tries to do a job and does not worry too much about himself, he does not have to worry about his friendships.

For instance, I consider that all of the members of Congress are my friends. I do not know too many of them personally, but I am sure that you are all my friends. I do not think there has ever been a single occasion where I have ever been asked to, or have ever done anything out of line for any Member of Congress, and yet you are still my friends.

The CHAIRMAN. I would not want you to say that you never did a thing for a friend, whether in Congress or out of Congress. You would not want the record to show that.

Admiral RICKOVER. Not where Government money is concerned.

The CHAIRMAN. Well, that is a different proposition. All things being equal, you would give a friend a break, would you not?

Admiral RICKOVER. Oh, yes. For instance, if I lived in your district, I would probably vote for you.

Mr. KEATING. That is the friendliest thing you could do.

Admiral RICKOVER. I would like to get back, if I may, Mr. Sisk, to discussion of the question you asked me.

I assume that Congress will probably set up a committee. I gather from the tenor of the questions and what I have read in the papers that that is so.

You should try to keep people off that committee who might be interested in it solely because of its glamour or because Members will be able to make profound statements which the press prints, and so on.

You should really try to get Members who are sincerely interested in this program, and regardless of their seniority.

At the closed hearings we had with Mr. McCormack recently, I suggested to him that he already had a pretty good job in Congress and he need not try to become chairman of this committee; he agreed with me and stated he did not want to be the chairman.

Mr. FULTON. A lot of us think he ought to be.

Admiral RICKOVER. He ought to be, but he cannot put in enough time on it. Certainly he ought to be, but he knows what I meant by that. I simply say with all of his other honors he does not have enough time to take over a committee.

The CHAIRMAN. Thanks, Admiral, for recognizing my problems.

Admiral RICKOVER. I do. And furthermore, you have done enough for your district already.

The CHAIRMAN. Can you convert some of my enemies?

Admiral RICKOVER. In 1946 the first Chairman of the Atomic Energy Commission was Brien McMahon, a first-term Member of the Senate, who had not even been in the House. It was very fortunate for this country that a man as dedicated as Mr. McMahon, and as intelligent, and who worked as hard, got the job. He never permitted any politics to enter into it. I hope in the assignment of members to this committee you will disregard all questions of seniority and political party.

The committee must become a body that people recognize has a very important national function in addition to its congressional function. It is because the members of the Joint Congressional Committee on Atomic Energy have been so dedicated that they frequently have been listened to by all of the Congress even at times when the cause they were espousing was not popular. Congress has listened to them because they felt they were doing it for the good of the country and for no other purpose.

Mr. SISK. Admiral Rickover, in view of your concern regarding the aspects of education and so on, let me ask you this:

Do you feel that at the present time we are fully utilizing our engineering and scientific capacities and manpower that are actually available to us in the United States?

Admiral RICKOVER. No, sir, we are not fully utilizing these capacities and people.

One obvious way we are not utilizing these people is because a considerable number of them go into business, where they get paid more than they do in science as in engineering. You cannot very well blame a man who has a family because he does not work in a profession where he cannot support his family.

That is true of our teachers, too. I place a higher priority on teachers, on improving their abilities and increasing their salaries than on scientists and engineers because we are not going to have good scientists and engineers unless we first have good teachers.

Again I would like to get back to the basic issue, if you will pardon me, and that issue is the quality of our teachers.

Mr. SISK. All right, then; that calls for additional pay and additional money.

I felt just a bit of criticism on your part, probably, of the fact we cannot talk in small sums around here. We, then, in Congress must see to this—will you agree?—that better salaries are provided not only for scientists and engineers who are now devoting their ef-

forts to the particular problems we are concerned with, but to the teachers at university level, and so on? Is that correct?

Admiral RICKOVER. Yes, sir; that is correct. I would like to discuss this matter in two parts.

First, the question of scientists and engineers, and second, that of teachers.

As far as the Government is concerned, I believe Congress has been generous in the pay scales for scientists and engineers. They get paid pretty well.

The Federal Government does a good job in paying professional people. I think if we were a little more strict and checked up on some of the high-paid civil service people, we would find some of them are not too well qualified. I would not worry too much about the pay of civil service scientists and engineers because, after all, once a man is able to take care of his family, he achieves a great deal of pleasure, of professional recompense, for working in his field.

The scientist and the engineer who really does his job leaves a lasting monument. He can take pride in his accomplishments, and that is worth something, too. Money is not everything.

I think you have done pretty well with the present salary scale for scientists and engineers in Government. I will leave that and get on to teachers.

For our teachers we certainly do not do enough. We entrust the future of our children to them and yet treat them as second-rate citizens. This is where we could use some Federal money. You could set up standards for teachers, and urge them to qualify to these standards. Then I would have the Federal Government augment any deficiency in teacher salaries in those States which do not pay their teachers adequately. But this additional money should go directly to the teachers and not through State Boards of Education or professional educators—those who require our teachers to take courses in how to teach plumbing, fly casting, window opening, and such trash.

This is the pernicious thing that is contained in some of the aid-to-education bills. It is not all lack of money. Money could be spent better in helping teachers to become qualified to do their jobs. Then, if the States are not rich enough to pay them adequately, and provided the teachers can demonstrate proficiency, let the Federal Government make up the difference in salary directly to the teachers.

Mr. SISK. Do I understand you to mean that in the Federal education bill we might put some provision to provide for better paid teachers instead of, let us say, patios and swimming pools?

Admiral RICKOVER. Yes, sir.

I was at a meeting the other night in Baltimore, and a contractor who erects school buildings told me: "I tried to sell them the idea they can build some of their school buildings simpler and cheaper. It is going to hurt me financially to put up cheaper school buildings because my fee depends on the cost of the contract. Nevertheless the professional educators will not let me build the cheaper ones. They want to have expensive frills because they like to be in charge of fancy structures."

These educationists are pure administrators and they mostly think in terms of large facilities, not of intellectual matters. It is not

necessary to have large expensive school buildings. In the early days of the Atomic Energy Commission they found that they could not even put up a school building on a lump-sum contract. They put up a school building at Hanford, Wash., on a cost-plus-fixed-fee contract at a very high cost. This was eventually investigated by the Joint Congressional Committee—why a school building could not be built on a fixed-price basis.

I am not in favor of elaborate buildings. I would rather have a good teacher in a barn than a poor teacher in a palace.

Excuse me for sticking to this subject, but if Congress really wants to do the most important thing to help the United States, you would get after the question of teachers' standards and salaries, and what the pupils must know when they get out of school. I would have a national examination and I would have every child take that examination when he finishes high school, and see how well he does. Then his father and mother could tell whether the schools have done a good job.

Congress has set up laws for what goes into people's mouths, but you will not even provide for a recommendation for what is to go into their heads.

Mr. SISK. Admiral, I fully appreciate your concern with that. I think I have some concern on that score myself, as far as the direction the education program has gone.

Let's get back to the immediate future with which we are concerned in this space age in which we live, and that is the full utilization or what we may be able to do from the standpoint of Congress in fully utilizing the present existing scientific and engineering brainpower which we possess. We discussed the salary question because that was the first thing you mentioned. You actually wound up by saying that you felt we paid rather well as far as Government was concerned.

Admiral RICKOVER. Yes, sir.

Mr. SISK. Then somewhere a recommendation or a program to utilize fully this brainpower, which I think is important, can be developed.

Admiral RICKOVER. I do not think you can do this by legislative fiat, sir. It depends almost entirely on the man you put in charge. You cannot sit in a congressional committee and tell a man how to run this job. You can ask him questions; you can ascertain whether he does a good job; but you cannot put that into the law, because it is a subjective matter.

I urge, based on my own experience, that you do not let this new agency get started full blown. Let it get started modestly. Let it develop as circumstances warrant.

Mr. SISK. On the educational problem let me ask you this:

Going back into history a little bit, and referring to the fact that, as a country, we have a quite short history, we have created a nation that is certainly considered to be one of the leading nations of the world, and we have created a lot of good things for people. We have a lot of ingenuity, I think. You do not think that our education has always been wrong, but we have recently defaulted?

Admiral RICKOVER. I feel we have been living off our capital and not entirely off our current earnings. People came over to this rich, vast continent and have used its resources too wastefully, and without

enough consideration for our posterity. Our standard of living today is not based altogether on what we earn; it is based on using up irreplaceable natural resources. If we really lived on what we actually earned, we would not have so high standard of living.

The countries of Europe have had to husband their resources for the past 300 years and they found out the only way to get along on meager resources and still have a reasonable standard of living was to properly educate their people.

For instance, the countries of Western Europe have an educational system based on the lessons of 2,500 years of western civilization. In the past 50 years we, in this country, have broken with that system of education. We have gotten away, a great deal, from the basic rigorous studies: mathematics, physics, chemistry, science, history, languages. We have broken with this rich cultural past. The object of our public schools has become to make the children happy—"happy ants" as Senator Flanders says. Unless we change quickly and get back to training our youngsters in a rigorous, hardheaded manner we are in for a great deal of trouble. We must not permit our children to be deluded that life is all fun.

Mr. SISK. Do you agree with some of the testimony here before this committee a few days ago that actually we are still ahead of other countries of the world in basic research, astronomics research, and so forth, but actually today we may be behind in hardware? Do you agree with that statement?

Admiral RICKOVER. I am just a simple naval officer. When I see the Russians putting a sputnik in orbit with a payload much greater than we can get up, in my untutored and unsophisticated way I conclude that the Russians are ahead. I know of no other way to judge. So what I see is different from what I hear.

Mr. SISK. I go back to the question asked you by the chairman of our committee when we started the hearings this morning as to the peril which we face and the importance of the problem to the next generation.

I felt at that time that you were rather downgrading the importance of it.

Admiral RICKOVER. I believe you are touching on two separate subjects. I said that for the immediate future we are not going to find protection in space ships and space cadets. We are going to be protected by the military forces we have now and those we are now developing, particularly missiles.

I thought I made that clear—that, in my opinion we will develop operable missiles sooner than we will develop space vehicles which could be a controlling factor in warfare. This is what I mean.

The CHAIRMAN. My impression is the same as Mr. Sisk's of what you said, that you did not think there was so much urgency on the part of this committee.

Admiral RICKOVER. I said I did not think there was so much urgency for the space agency as there was in 1946 for the Atomic Energy Act. That was my comparison.

The CHAIRMAN. I think you failed to consider what I had in mind from the angle of the time element, because in 1946 and 1947 the Soviet Union were not anywhere near as far advanced, so far as we know, in the atomic energy field as we were.

Admiral RICKOVER. I believe we can get ahead with this job without very large expenditures of money at this time. I think it boils down to that.

Many of these new developments just take much time to accomplish. I believe you were talking about a crash program, whether we should enter into a crash program.

The CHAIRMAN. The word "crash" is used descriptively in the sense of an effective program, not a lagging one.

You know the history of the Manhattan project pretty well?

Admiral RICKOVER. Yes, sir.

The CHAIRMAN. You know there were many who doubted that that should be gone into.

Admiral RICKOVER. There is no doubt as to whether we should work in the space field.

The CHAIRMAN. I mean, many opposed the Manhattan project.

Admiral RICKOVER. Yes, sir; I know that.

The CHAIRMAN. And you know it was a gamble.

Admiral RICKOVER. Yes, sir; know.

The CHAIRMAN. I know, because I was one who had to help raise $1.6 or $1.8 billion in 2 fiscal years without the Hitler government knowing we were doing it. We were told at that time it might be $2 billion thrown down the drain.

Admiral RICKOVER. But you know, Mr. McCormack, a man is always put on the defensive if he opposes anything. Do not forget that. He is in an unenviable position. I certainly am not opposed to this new agency and its proposed work, you understand, but traditionally the man who is an optimist and supports everything that is proposed always comes off best.

The CHAIRMAN. We are not discussing that.

Admiral RICKOVER. You are discussing that, really. You say you are not, but you really are. It is difficult for a witness who tries to throw some balance into a discussion where many others talked about it in grand terms. It is an awfully hard position to be placed in.

The CHAIRMAN. It is just like being against motherhood.

The CHAIRMAN. Just to give you a little basic thought in my mind, as a result of experience. Of course in the legislative field we have experiences, too, and encounter many difficulties in the passage of legislation. I can remember the Selective Service Act, 3 months before Pearl Harbor, passing the House by one vote. I led the fight for it. Everyone who voted against that bill was just as good an American as I, but there was that difference of judgment.

One of the basic things, of course, that I advocate, whether right or wrong, is that if I am going to err in judgment in these days I prefer to err on the side of strength rather than on the side of weakness.

Admiral RICKOVER. That decision, of course, is one that Congress must make. I can only give you my thoughts.

I will try to summarize them.

I think this matter of space is important. It should be run by a civilian agency. It should get the money it needs, but I say you do not need a crash program, and I doubt that it will get ahead faster by appropriating large sums of money right away.

I would rather have the agency organized in a moderate way at first, have the people in it become partners with their own Joint Congressional Committee and then mutually work out what they have to do.

That is what I am saying. I am not against such an agency. I want to make that very clear.

The CHAIRMAN. You have clarified my thoughts with regard to your testimony on the urgency of creating by law the agency which will administer this.

Admiral RICKOVER. Yes, sir.

The CHAIRMAN. Mr. Sisk, may I ask one question without interfering?

Do you think from the view point of decision-making that the agency head should be on high level?

Admiral RICKOVER. You mean in the Government?

The CHAIRMAN. Yes, as close to the President as possible, access to the President.

Admiral RICKOVER. You might do this, but ultimately you get where every decision has to go to the President, and obviously that is not desirable.

The CHAIRMAN. He is the Commander in Chief and the President of the United States. We know his powers under the Constitution.

Admiral RICKOVER. I might suggest you start it off with the same status the Atomic Energy Commission has. That is a pretty good status, and I believe the President does pay a great deal of attention to it. Then see how it works out.

When you pass the act for this agency you must assume it is a trial piece of legislation. Start it out, give it standing, and see how it works out. Change it later on as experience indicates.

The CHAIRMAN. In the light of the experiences of the Atomic Energy Commission, with which you are well acquainted, if you had that knowledge and that experience 10 years ago would you put the Atomic Energy Commission on a higher decision-making level?

Admiral RICKOVER. No, the Atomic Energy Commission is high enough right now.

The CHAIRMAN. But the Atomic Energy Commission is higher than what this bill proposes. You know that.

Admiral RICKOVER. You asked me that question before, and I told you the decision to put it in the NACA has probably been made by people who had access to all of the facts. The agency could also be made a separate purely civilian agency, but this is something you have to decide.

The CHAIRMAN. That is true. But I mean, whatever agency it is put into, do you think they should be put on a high level so far as decision-making is concerned, and access to the President?

Admiral RICKOVER. We are dealing in a field we do not fully understand yet. I am sure everybody agrees with you that it is highly important and essential, so I would start it high up, give it as much standing as the Atomic Energy Commission. It needs no higher standing.

Does that answer your question?

The CHAIRMAN. Yes.

Admiral RICKOVER. You could do it one of two ways: You could set up a separate civilian agency or you could elevate the NACA—whichever one you wish.

The CHAIRMAN. I want you to answer the questions. It gives me evidence which I can then evaluate.

25973—58——17

Admiral RICKOVER. I would put it as high as the AEC, but that does not necessarily mean it has to be extensive, sir.

The CHAIRMAN. Oh, no.

Admiral RICKOVER. Again I get back to the fact that the importance of an agency is not necessarily measured by the number of people it has. This is the dilemma, this is the thing you have to watch. In fact, if you make it too large, you may harm it.

Mr. O'BRIEN. Will the gentleman yield?

Mr. SISK. Yes.

Mr. O'BRIEN. I would like to clear up my understanding, Admiral, of this urgency. I think I understood you to say that this problem is urgent, but you believe we would reach our destination quicker and more efficiently if we take the road labeled "Research" than if we take one just cluttered up with the hardware?

Admiral RICKOVER. That is right.

Mr. O'BRIEN. Is that right?

Admiral RICKOVER. Yes. Let the hardware come when we see we have something worthwhile. Let's not start in with hardware.

Mr. SISK. Is it your opinion then, Admiral, that the fact the Russians were able to put substantially greater amounts of hardware into orbit than we were was due to the fact that they are ahead of us on basic research?

Admiral RICKOVER. In the space field; yes, sir. It is definitely my opinion that the Russians are ahead of us in that particular field, and that was due to the vast amount of effort they have placed on research and development.

Mr. SISK. I think that is rather important in the light of some testimony we have had before, and I think it is fine to have disagreement.

Admiral RICKOVER. I am talking as a layman. I read in the paper that they placed in orbit an object several times as heavy as we are capable of. If there are two people in a prize fight, and the first one punches five times as hard as the other you say the first one is the stronger man.

Mr. SISK. I appreciate your statement.

Admiral RICKOVER. I do not care what other explanation you get.

Mr. SISK. There is one other line of questioning, Admiral, and I do not know to what extent you may wish to comment on this. If you do not desire to comment at this time, simply say so. That line of questioning is this: In view of your experience on the job you have to do—and have been doing very excellently, I might say—what do you feel might be the application of nuclear propulsion to space vehicles?

Admiral RICKOVER. You are aware, Mr. Sisk, this is not my specific field of responsibility. But I believe that ultimately if we do get space ships, they may be propelled by atomic reactors.

You know, of course, that not much thrust is needed to propel a ship in space. Nuclear power may also be used to launch space ships. It may be that the best way to launch space ships and then power them in space is by atomic energy. It certainly should be looked into.

Mr. SISK. Do you feel we are at present doing all we should be doing about development and research in that type of program?

Admiral RICKOVER. One never does enough in research on anything. That can always be said. There is a program underway. It has certainly not suffered from lack of appropriations. I think the problem is lack of adequate scientific and engineering manpower.

I am convinced from my experience in the Atomic Energy Commission that no one who has been able to prove he could do a job and was ready to do so was ever denied money by Congress.

Certainly, in my own field, Congress has been more than generous to me. I get all the money I ask for—all that I need.

How do you like that for a statement from a bureaucrat?

Mr. SISK. The concern I have is not whether it is the fault or lack of fault of Congress or someone else. I am concerned whether or not we are proceeding with the proper type of reactor program. I realize you may be hesitant to make some comments here, but I would appreciate your very frank statement.

Admiral RICKOVER. Have I demonstrated any hesitancy up to now?

Mr. SISK. I might say, Admiral, I appreciate your frankness.

Admiral RICKOVER. No, I am not hesitating at all. There are certain fields that just cannot be pushed too fast.

For example, the big problem in atomic reactors is the harmful radiation effects on materials. It takes 3 to 4 years of testing in a test reactor to find out whether a sample of material will stand up under radiation.

In a missile engine, the materials need only operate for a few moments, so the problem is vastly simpler from a materials standpoint than it is in a nuclear reactor. In a missile the material can be used at very high stresses; it can be partly destroyed, all that is necessary is that it last for just a few moments. But in an atomic reactor the materials must last for several years. So it is significantly more difficult materialwise and takes a much longer time to design and develop. You cannot just order the materials for a reactor to be developed; it takes time, and money alone will not solve the problem.

In the last 20 to 30 years we have improved the ability of some materials to withstand temperatures only a few hundred additional degrees Fahrenheit. The curve of possible increased temperature is flattening out.

It is an extremely difficult problem. That is why there is not more progress. There are materials that are good for every other purpose except in a reactor. Place it in a reactor and very quickly it swells. It loses its shape. It closes the heat transfer passages. It burns out and releases a great deal of radioactivity. It takes several years to find all this out. That is why it is not the kind of a job we can do fast.

Mr. SISK. Mr. Chairman, just one more question and then I will conclude.

Do you agree or disagree with the statement attributed to a prominent scientist that the problem of developing nuclear propulsion for a vehicle of this type would be easier to accomplish now than the development of the atomic and hydrogen bombs were at their inception?

Admiral RICKOVER. No. My opinion, for what it is worth, is that it will be more difficult to develop propulsion for a space ship than it was to develop the atomic bomb or the hydrogen bomb.

Here is why: In a bomb the most difficult part is the development of the scientific formula. The bomb designer does not have to worry about his materials lasting for a long time. They need last for just a very small fraction of a second. The development of power reactors is far more difficult from a materials standpoint than the development of the bomb.

Mr. Sisk. Thank you, Admiral.

The Chairman. Mr. Fulton.

Mr. Fulton. Admiral, we are glad to have you here, and we know the good work you have been doing out around Pittsburgh and in highlighting the nuclear submarine program.

You have been on the stand now an hour and 45 minutes.

Admiral Rickover. I am still going strong, sir.

Mr. Fulton. I would say that, from your remarks you would say that this program should be conducted on a basis of putting vehicles into space, regardless of military considerations; military considerations should come second, is that not right?

Admiral Rickover. That is correct, sir.

Mr. Fulton. Then you would say in order of importance, not of priority, that education in the United States to you is Congress' most important program. Secondly, the proper use of our United States resources is next, in your mind. And thirdly, the problems of outer space are probably last. Is that right?

Admiral Rickover. Yes, because if we solve our educational problem, we are then on the way to solving all the other problems. That is, we solve our resources problem, also. We cannot solve any of these problems unless we have highly educated and intelligent people. This is the basis for my priority.

Mr. Fulton. Your exposition is that the Manhattan project which later became the Atomic Energy Commission should be considered in this instance as an example for our national space program. Is that not right?

Admiral Rickover. That is correct, sir.

Mr. Fulton. And that, under the Manhattan project, one of the basic elements of it was that the authority and responsibility were centered, which you like?

Admiral Rickover. Yes, sir.

Mr. Fulton. You likewise emphasize the fact that this is a recent research and development program rather than a manufacturing or production program, do you not?

Admiral Rickover. Yes, sir; certainly at the beginning.

Mr. Fulton. Another point that you made was that you seemed to put more emphasis and more weight on the person who ran the program than the particular agency or structure by which the program was implemented.

Admiral Rickover. That is correct, sir.

Mr. Fulton. So, if a program is set up, you want a direct responsibility both to Congress and to, possibly, the President or the administration by any particular agency that is set up, so that we will not have an advisory committee wandering around and later causing us trouble. Is that about right?

Admiral Rickover. That is correct. He should have advisory committees, but the advisory committees should not be groups of meddlers, nor should they control him.

Mr. FULTON. And he should have a responsibility which Congress controls and the particular agency should control.

Admiral RICKOVER. Yes, sir.

Mr. FULTON. So that agency does not have to fight the advisory committee?

Admiral RICKOVER. That is right. In other words, you notice the gist of my testimony is I have placed a lot of faith in Congress.

Mr. FULTON. Thank you. May I ask then, when you suggest a Manhattan-type project setup, would you not have in mind a military man as head of the Manhattan project rather than a civilian of a scientist type, or a management type; is that right?

Admiral RICKOVER. It does not matter whether he is a military man or a civilian, a scientist or a manager. I do not think you can separate these things into pigeonholes. A scientist can be a good administrator, and an administrator may have learned a great deal about science so that he can run the job.

As rule, I would not put a scientist in charge because, generally, the scientist has used his time fully in scientific pursuits, and is not too familiar with administration. I certainly would not put a pure administrator in, a man who knows little about science and engineering.

Mr. FULTON. Would you put in a businessman or would you put in somebody in Government?

Admiral RICKOVER. I would rather put a man from Government in.

Mr. FULTON. Why would you not put in a businessman?

Admiral RICKOVER. The businessman has been trained to have a different set of values than are needed for this purpose.

Mr. FULTON. Would he not be competent to run a large research and development project such as this, which would have a great deal of management and many business contacts to make?

Admiral RICKOVER. Yes. He may have too many business contacts to make.

Mr. FULTON. It sounds as if you are suspicious of the businessman.

Admiral RICKOVER. No, sir; not especially. I am suspicious of everybody.

Mr. FELDMAN. Including yourself?

Mr. FULTON. Seriously now?

Admiral RICKOVER. The businessman generally comes to the Government for 1 or 2 years; you will never get this job done with transients in charge.

Mr. FULTON. How many men in the country do you consider are competent to head this agency for the large job of research and development that is to be worked out?

Admiral RICKOVER. There are not too many. I testified in your closed hearing I thought there were possibly 15 to 20 people in the United States who would be capable of handling a large scale research and development job of this sort effectively.

Mr. FULTON. But you would not want to submit a list of those names you felt were competent?

Admiral RICKOVER. No, sir; because there would probably be 173 million different opinions on a list of this sort.

Mr. FULTON. Then on the question of money, you would keep the money in low amounts, aimed specifically at research and develop-

ment, for scientific talent, and not for the production of military hardware. That is another point.

Admiral RICKOVER. Yes, I would keep the production of hardware at a minimum to start off with, because in order to make this hardware there must be a vast establishment. You can easily be wrong. So the money may go for the construction of large scale and expensive facilities and hardware.

I would use existing facilities, either governmental or industrial, if at all possible.

Mr. FULTON. Suppose that you put a space satellite or vehicle into orbit and put it out about 26,000 miles and gave it a speed to match the rotation of the earth. It would actually just stay over one city, would it not?

Admiral RICKOVER. Yes, it would. You could ultimately control a space vehicle so that it could stay over any particular part of the earth.

Mr. FULTON. So we could then actually, in the United States, put up space vehicles that would just go right around with the earth and remain over any particular city of the whole world all the time?

Admiral RICKOVER. Yes, sir; you could.

Mr. FULTON. And never move. Could you not do that?

Admiral RICKOVER. That is correct.

Mr. FULTON. How close do you think we could bring those to any cities of the world and not get into trouble on the ground it was invading their territory or causing them some qualms about their defense—100 miles, 200 miles?

Admiral RICKOVER. I have no particular idea about that, sir. You know that the present law goes back to Roman times, that the man who owns a plot of land owns everything above it and below it. The extent to which he owns it above and below has never been clearly defined.

This is an issue that should be settled from an international law standpoint. If you can settle that issue you probably will not have any more wars. You can then settle the business of disarmament, too. This problem of space may force a new look at other international situations. If we can solve this problem, we may be solving other problems, also. That is a major reason why it should be a civilian agency; a civilian agency can more readily lead to a peaceful solution.

Mr. FULTON. In your position, you would emphasize research and development to find out the scientific facts; you would then oppose at this time a shot at the moon for propaganda purposes or a hurry-up or crash program for a lunar shot, would you not?

Admiral RICKOVER. I would oppose anything for purely propaganda purposes. I do not think that propaganda ultimately does as much good as some think it does.

For instance, it is said that sputnik has propaganda value. The sputnik was a fact. Propaganda has nothing to do with fact; it has to do with distortion of fact.

Mr. FULTON. Did not the sputnik going up first impress you? Why should we not then in the United States try to get to the moon first before Russia does?

Admiral RICKOVER. I was impressed. But the real lesson of sputnik was not that the Russians were able to get an object in orbit 2 or 3 months ahead of us, but the fact that it became obvious to our people

that the Russians were able to get a much heavier payload up. That is not propaganda. It can be called propaganda, but it really is not. There is not distortion of fact.

Mr. FULTON. The question comes up, then: If you emphasize purely the scientific in the missile field and space vehicle field, would you do the same in the nuclear submarine field, because with Russia having over five hundred submarines at the present time and we having so few nuclear submarines, do you not think that we in the submarine field in the United States should start with a greatly expanded hardware program?

The point is this: If in the environment called the sea which is necessary to the United States in its security, you have an expanded program that is producing hardware of a nuclear type and a faster type of submarine, why then in the environment called air, and in space, which is necessary for the United States security, should we not have an expanded program of hardware?

Admiral RICKOVER. We started off in our nuclear submarine program with research and development. We did not build large numbers of nuclear powered submarines until we had proved them.

Mr. FULTON. Then in what period of time would you envisage that this program should greatly expand itself in order to have an array of missiles, or whatever they are, in order to meet anything that any foreign power might be able to throw against us?

Admiral RICKOVER. That would depend entirely on what progress we make in research and development. As soon as research and development demonstrates that a particular object could be put into production, I would do so. But I would not start in building large quantities of space vehicles until I knew what I was doing. This was our aproach in the nuclear submarine program.

Mr. FULTON. You would not, then, go into a program at this time of an ICBM with a nuclear warhead nor would you expand the guided-missile field on the intermediate range, 950 or 1,500 miles?

Admiral RICKOVER. No, sir, I did not say that. The missile field is much further advanced than the spaceship program. So is the nuclear powered submarine. We have considerable technical foundations on which to go ahead and take chances.

What I am trying to say is that we do not yet know enough about spaceships to go into large-scale production. I would want some of the technology to be proved before we get into a large production phase.

Mr. FULTON. You would not, then, try for a space vehicle that could be used for reconnaissance purposes at this time in, say, some quantity so we could see what is going on in the world?

Admiral RICKOVER. I would first like to find out if I could build one before I would start building large quantities of them.

Mr. FULTON. Thank you very much.

Mr. O'BRIEN (presiding). Mr. McDonough.

Mr. McDONOUGH. Admiral Rickover, I understood you to say that we were not advanced as far as Russia in basic research development.

Admiral RICKOVER. In this field, sir.

Mr. McDONOUGH. In space technology, you mean?

Admiral RICKOVER. We are not, sir.

Mr. McDONOUGH. That does not apply to atomic technology then?

Admiral RICKOVER. I am not familiar with the atomic aspects of

nuclear weapons, that is, the comparison between the Russians and the United States. It is my opinion that they are not any further advanced than we are in the nuclear power aspects. We see no evidence that they are.

I am basing my opinion simply on the evidence, on the evidence there is.

Mr. McDONOUGH. The reason I made that point is that General Medaris and Dr. von Braun both stated that we were equal with Russia in basic research and development.

Admiral RICKOVER. In this field?

Mr. McDONOUGH. In space technology and in the development of space exploration. They admitted that the operational situation in Russia was slightly more advanced because they had thrown a heavier satellite into orbit than we have. Now they are both right in the field, and I would say they ought to know.

I was a little surprised to hear you say we were not equal on basic research, because, after all, both the United States and Russia are certainly following along the same basic natural laws. We both know it. The throwing of a satellite into space by Russia is done by using the same principle that we do in this country.

Admiral RICKOVER. Mr. McDonough, my opinion is based entirely on what they have done. I have no other way of judging. What I see is different than what I hear.

Presumably General Medaris has information that I do not have. I only know from the published statements. As far as I am concerned, the Russians have done a better job than we have in this field, and I believe it has taken them many years to reach this point. You just do not do it by deciding today that next year you are going to place a heavy payload into orbit.

Mr. McDONOUGH. You mean they have done a better job in throwing satellites into orbit?

Admiral RICKOVER. In my opinion, they have done a better job than we have in research and development in space matters and in the related aspects of placing objects into orbit. That is why they were able to launch one with a heavier weight.

Mr. McDONOUGH. Both Dr. von Braun and General Medaris also admitted that we have the industrial know-how, we have the manpower and the technical and scientific brains in this country, if they are marshaled and coordinated. Do you agree with that?

Admiral RICKOVER. I am not sure about that. I am not so sure we have enough highly trained people to do some of these very difficult things; one reason being, we are tackling too many problems, and we are spreading our qualified people too thin; we are duplicating too much.

If there is any genius to what the Russians have done, it is that they have concentrated on a smaller number of what they consider essential items, and they do these well. Trained people are necessary to do a job well. There is a great danger that by tackling too many problems at one time our talent is dissipated. A certain type of drive is needed in a project that is going ahead and is meaningful. There is the need to train people, to have them become dedicated to the job; it is not numbers of people that count.

This is where we make a mistake. We depend too much on numbers. One good scientist or engineer is worth a hundred mediocre ones. We just cannot equate quality with numbers.

We must not delude ourselves that the Russians are not ahead of us in this field.

Probably General Medaris and Dr. von Braun know more about this than I do. I get the same type of intelligence you get, and what I see, as I said, is different than what I hear. As I have no other explanation, I naturally assume the Russians have done a better job.

I am familiar with what the Russians have been able to do in education in the past 30 years. That, to me, is proof of why they are ahead.

Mr. McDonough. How is the space technology in the Navy compared in progress to the Army and the Air Force?

Admiral Rickover. Well, space belongs to the Air Force, sir.

Mr. McDonough. You, however, have developed the Vanguard and shot that after several failures.

Admiral Rickover. How does the space research work in the Navy compare to the others? Probably the Army has done about as well in space as either of the other two services.

Mr. McDonough. We have the three major services all devoting a lot of attention to this matter, and there is competition there, and there is a certain amount of interagency jealousy, I suppose, in that competition as to who is going to be first with what.

Do you think this is a good thing, or should we concentrate this effort, put it under one command, one direct line of authority, and proceed that way?

Admiral Rickover. I understand the purpose of your bill, with which everybody seems to agree, is that the major research and development responsibility will be centered in one agency. I think you should do it this way. One agency can assemble competent people more readily than several agencies competing with each other.

I do not mean by that the military should play no part in it. When we get to the stage where we are producing military items, the military should have responsibility too.

Mr. McDonough. The bill provides for a board of 17, with one man from the Defense Department. Is that sufficient?

Admiral Rickover. I would have more than one from the Defense Department, sir.

Mr. McDonough. Would you have a representative from each one of the major services?

Admiral Rickover. No, sir. I was asked that question before. My recommendation is to let the Secretary of Defense decide what military members should be on the board. I would not specify that they must be from the Army, Navy, or Air Force.

Mr. McDonough. As the organization now exists, with the Secretary of Defense, Dr. Killian, and Mr. Johnson, do you think that organization is accomplishing anything at the present time?

Admiral Rickover. It is out of my field, sir. It is a new organization, and I am not familiar with what it has accomplished.

Mr. McDonough. You are familiar with nuclear power, having developed the *Nautilus*. Do you think that we can send a spaceship in orbit easier with nuclear power than we can with chemical power?

Admiral Rickover. Not at the present time, sir.

Mr. McDonough. Do you think we could send one with chemical power into orbit?

Admiral Rickover. Well, we have sent one up with chemical power, and we have not sent one up with nuclear power.

Mr. McDonough. I mean a space ship, not a satellite.

Admiral Rickover. Nuclear power for a space ship is certainly not developed at the present time for doing that job.

Mr. McDonough. Are you familiar with the chemicals that are used?

Admiral Rickover. I am generally familiar with them from reading technical publications, sir.

Mr. McDonough. That is all.

Mr. Fulton. Will you yield? Admiral Rickover are you getting around to this question?—is there a possibility that the Russians have developed atomic power to the point where they can send a spaceship into orbit?

Admiral Rickover. My opinion is they do not have it.

Mr. McDonough. Do you know?

Admiral Rickover. I do not know. It is my opinion that they do not possess it.

Mr. McDonough. First, you said the big thing in atomic power is radiation.

Admiral Rickover. Yes, sir.

Mr. McDonough. And to prevent radiation to the occupants of the spaceship is one of the big problems, plus the weight of the reactor.

Admiral Rickover. That is right.

Mr. McDonough. What would be the minimum weight, in your opinion, of a spaceship with one man?

Admiral Rickover. I am not technically qualified to answer that question.

Mr. McDonough. What is the minimum weight—you know more than I do about nuclear power. How much of a reactor would you need to send a spaceship up?

Admiral Rickover. My field is nuclear power for ships, where we use machinery which is heavier than we would use in an airplane or in a space ship, where we are limited to much lower weights.

The Atomic Energy Commission, in conjunction with the Air Force, as you know, has been working for some time on that problem. It has not yet been solved. I thought you were getting at the point that the Russians might have the capacity to launch a spaceship or place in orbit a very heavy object by means of nuclear power; my best judgment is that they do not.

Mr. McDonough. That is merely a presumption on your part; you have no assurance?

Admiral Rickover. Well, it is a presumption based on what we know they have done in the entire field of atomic power. We do not know that they do not have a nuclear powered submarine, but we have seen no evidence that they do.

Mr. McDonough. Just for speculative opinion, why do you think Russia has not shot any more satellites into the air since they shot the two, and there has been a long period of suspension there. We have three of them now, and they do not have anything. Why?

Admiral RICKOVER. I do not know. I imagine they may be working on placing something in orbit which surpasses anything they have launched so far.

Mr. McDONOUGH. Spectacular.

Admiral RICKOVER. Yes. But it needs to be more than spectacular, sir. If it is spectacular, it also means a great deal of scientific and engineering work had to be done to make it spectacular.

The CHAIRMAN. It might also surpass what they have heretofore done?

Admiral RICKOVER. Yes. I see no point to their placing additional missiles in orbit unless they were heavier or they wanted to get more information from animals or possibly from human beings sent up in them. I certainly believe they will try, as soon as possible, to get a human being into space and have him return to earth so they can find out what went on.

Mr. FULTON. Will the gentleman yield?

Mr. McDONOUGH. Yes.

Mr. FULTON. You have said that space belongs to the Air Force. As a fellow naval officer, I would suggest to you that it does not belong to any military service and does not even belong to the Americans.

Admiral RICKOVER. I was joking, sir. The simple way of dividing the world is to say that anything on land belongs to the Army, anything in water belongs to the Navy, and anything in air belongs to the Air Force.

Mr. FULTON. But when you get beyond the air out into space, to whom does it belong?

Admiral RICKOVER. Of course, this is the big problem and will come on us soon.

One of these days an object from space which has been launched by one country or another will land in somebody's backyard; then the problem will reach real proportions.

Mr. FULTON. So you really do not feel, then, that space is an object for military exploration or dominion, but rather it is a field for scientific exploration; is that not correct?

Admiral RICKOVER. Yes. I would like to see space considered as belonging to all nations, just as the high seas do. You cannot separate its military aspects from the purely scientific, the peaceful aspects, sir. They are intertwined. You cannot make a real distinction.

Mr. FULTON. You do not mean that either one of them is going to dominate space, but rather, under a general space agency which might be set up by Congress, there is to be developed a national space policy which is to be both civilian and military?

Admiral RICKOVER. That is correct.

Mr. FULTON. And if possible, under President Eisenhower's arrangement, our national policy should be that space should be used for peace and not for war?

Admiral RICKOVER. And I do hope we take advantage of this new element to help bring about peace, to use it as a bridge for peace.

The CHAIRMAN. May I interject?

Mr. FULTON. I am through.

The CHAIRMAN. To say that is the Lyndon Johnson policy, too, as enunciated by him weeks ago.

Mr. FULTON. Yes, but the Admiral would disagree with Senator Johnson I believe, in that you would have the United States develop its own space program and national policy and not do it under the United Nations or another international agency?

Admiral RICKOVER. That is correct. We have not even been able to agree on how to exchange scientific information with our own allies in Western Europe. Then why would it be wise to take on, at the outset, a vastly more difficult type of problem.

Mr. FULTON. So you would just have a United States national space policy, not an international one?

Admiral RICKOVER. I would start off today with the development as a function of the United States. I would try simultaneously to get agreement from all nations that space not be used for military purposes. As far as research and development are concerned, we will not get ahead very fast if we start taking everybody in on everything at the very beginning. Duplication in research is healthy—it is beneficial to have other countries working on the same thing in research. But I definitely would be for complete exchange of information in this field with everyone.

The CHAIRMAN. Mr. McDonough, are you through?

Mr. McDONOUGH. Yes.

The CHAIRMAN. Mr. Keating.

Mr. KEATING. Admiral, right along that line, do you not think it is imperative that the nations of the world agree that outer space shall not be used for military purposes, and that an enforcible agreement be reached to that effect?

Admiral RICKOVER. Well, I, of course, agree with the first part of your statement; but if you know how to get an enforcible agreement, then you have licked the entire problem.

Mr. KEATING. Of course, I do not, but do you not think that should be our aim?

Admiral RICKOVER. Yes, definitely; and not only for space. Perhaps we can use space as a means for starting it. Perhaps it offers a new approach that can be used to trigger an agreement.

Mr. KEATING. Do you not think that our country should take the lead in that?

Admiral RICKOVER. Yes, sir. I would always have our country do that. Traditionally, the United States has taken the lead in trying to make peaceful arrangements with other countries—the various nonagression treaties and other pacts. That has always been our position. We were instrumental in getting the two Hague Conventions started. We certainly should take the lead.

Mr. KEATING. In that connection, would you not favor a congressional statement of policy similar to something which I have introduced, and others no doubt, to the effect that it is the sense of Congress that outer space should only be used for peaceful purposes?

Admiral RICKOVER. Yes, sir.

Mr. KEATING. Do you not feel that would have a salutary effect, both in this country and in other countries?

Admiral RICKOVER. It would have a salutary effect in this respect: That foreign policy is now almost the exclusive province of the President. It would be good if the chosen representatives of the people made such a statement of policy, to show how deeply our people feel about peace.

Mr. KEATING. Now I want to pursue a little bit more your statement in which you said, rather facetiously, as you say, that space belongs to the Air Force.

Do you look upon space as different in kind or simply different in degree from the air?

Admiral RICKOVER. I will go back to what I said earlier. The dividing line between military and civilian uses could arbitrarily be set at the altitude a missile reaches to travel a distance of 12,500 miles. That height is easily ascertainable. For a missile whose range is 12,500 miles there is a band of altitudes available for the missile flight pattern. The altitude chosen will depend on many factors. The interrelation of these factors will result in some maximum permissible altitude for a missile flight of 12,500 miles. The maximum height, probably in the order of several hundred miles could be used as a dividing line between the military and civilian utilization of the space lanes. The distance of 12,500 miles is the maximum distance a missile would be required to travel. The earth being 25,000 miles in circumference, 12,500 miles is the maximum distance between any 2 points on the earth. I would accept that height as the limit for military uses.

Mr. KEATING. As the limit?

Admiral RICKOVER. As the demarcation. It is not a scientific demarcation, but from a practical standpoint of delineating the difference between the military use and the peaceful use, I would accept that height.

Mr. KEATING. That is surface miles?

Admiral RICKOVER. Yes.

Mr. KEATING. How many miles is that straight up?

Admiral RICKOVER. It is several hundred miles up. I am not giving you the exact figure, but it is somewhere around that. For the missile to travel a distance of 12,500 miles it must go up several hundred miles, something on that order. It can be figured out exactly. I would make that the dividing line between the military and the peaceful uses.

Mr. KEATING. That is the first specific suggestion for a definition we have had.

Admiral RICKOVER. You are just as capable as I am of formulating a definition. You asked my opinion. I have given some thought to this matter.

Mr. KEATING. I am very glad to have you give it.

Admiral RICKOVER. You might possibly consider the figures as analogous to the 3-mile limit for international waters.

Mr. KEATING. But that does have the merit of being specific, that is, measurable?

Admiral RICKOVER. Yes, you can measure it because a missile fired under given conditions must follow a definite trajectory to reach 12,500 miles. I do not know what the exact figure is.

Mr. KEATING. It is readily computable?

Admiral RICKOVER. Yes.

Mr. KEATING. But not by members of this committee.

Admiral RICKOVER. Oh, yes, you could do it. I do not know what kind of a school you went to.

Mr. KEATING. Then you would say that of that area which we would designate "outer space" that that has elements and character-

istics which would make it different in kind from that area below that area, would you not?

Admiral RICKOVER. Yes, sir. This is an arbitrary definition, you understand, it is simply an idea. I am sure you can get other witnesses who could tell you, "Well, you can make the dividing line at the ionosphere or the stratosphere"; there could be many other definitions. This is simply an idea for marking the distinction between military and peaceful uses of space.

Mr. KEATING. In other words, if you were defining where the area would be limited to peaceful uses, and you were doing it on your own, you would fix it at that point?

Admiral RICKOVER. Yes, sir.

Mr. KEATING. We have had evidence here from both Army and Air Force officers, and now you are the first Navy officer to appear before us.

Do you believe that, in view of the fact that the rules and missions, the present services, do not contain anything about outer space as an area which could be a future battleground, that there should be a redefinition of the rules and missions of the three armed services?

Admiral RICKOVER. Now you are getting into the subject of reorganization. I though the subject of this committee was space. I prefer if I may, sir, not to get into any discussions on reorganization.

Mr. KEATING. I do not want to ask you anything you prefer not to answer.

Admiral RICKOVER. I would rather not, because this is a matter the Administration is handling in its own way.

Mr. KEATING. I did not mean to have my question relate to the reorganization act that has been recommended by the President. I did not mean it to have any relation.

Admiral RICKOVER. Because it does touch on that, sir, and I would prefer not to answer it.

Mr. KEATING. I would not want to press you.

Let me ask you this: With relation to this particular space agency which is envisioned in this bill, I agree with you about the unusual character of that section which says that this 17-man board—

may make recommendations to the President with respect to the appointment of the Director and the Director shall not be appointed until the Board shall have had a reasonable opportunity to make its recommendation.

Have you ever known of any similar provision in other legislation?

Admiral RICKOVER. I am not certain, but I believe the law setting up the National Science Foundation may have a similar provision. But the National Science Foundation has an entirely different function—it deals with pure research which generally has no urgency because you never know ahead of time what you will learn from pure research. In my opinion the new agency should not be hampered by such a large board which meets occasionally and also nominates the Director. This agency will have urgent development work to do, besides research.

Mr. KEATING. If you require that the Board make the recommendation in the first instance?

Admiral RICKOVER. Yes, sir.

Mr. KEATING. You would be inclined to think that would hamper it?

Admiral RICKOVER. Yes. The President is the executive. It is up to him to nominate the Director. He is at liberty to go for advice to

17 people or to 17,000 if he wants to. I do not know why you have to tie him down in this case.

Mr. KEATING. You place great stress upon the designation of the Director.

Admiral RICKOVER. Yes, sir.

Mr. KEATING. As perhaps the No. 1 and most important element.

Admiral RICKOVER. There is no other issue as important. If you get a good director who knows what has to be done and wants to do it, and who will not let obstacles stop him, you will get the job done—the board of 17 will not do it. In fact a large mandatory board may hinder him. A friendly congressional committee, which he will surely have, will be his greatest help and ally. This will certainly be the case for the first few years, and until the agency becomes "political."

Mr. KEATING. I gathered that overall in this legislation you have the feeling that the Director was not placed at a sufficiently high level or given sufficiently high authority.

Admiral RICKOVER. I answered that in reply to a question Mr. McCormack asked me as to whether the man——

The CHAIRMAN. The agency.

Admiral RICKOVER. Whether the agency or director should not have the same status as the Chairman of the Atomic Energy Commission. I am not discusing the dual job that Mr. Strauss the Chairman of the AEC has. That is, he is personal adviser for atomic matters to the President and also Chairman of the Atomic Energy Commission. But as I stated to Mr. McCormack it was my feeling that the head of the new agency should have as much status as the Chairman of the Atomic Energy Commission.

Mr. KEATING. That leads me to this question: Admiral Strauss, as the Chairman of the Atomic Energy Commission, as I understand it, does attend Cabinet meetings and could be said to have Cabinet status. Is that not your understanding?

Admiral RICKOVER. I think that is pretty much a personal relation with the President. The President has decided to have an adviser in atomic matters, and he chose Mr. Strauss because he has great confidence in him. But whether he does that or does not for this agency, should not, I think, be stated in the law. That is a personal relationship with the President.

Mr. KEATING. That is the question I have in mind. I personally feel that this is such an important area that the director of this agency should have the equivalent of a Cabinet status. Now, do you think that that is a matter for the President alone to determine or is it something to which Congress should give its attention as a guide?

Admiral RICKOVER. I do not agree with you that this agency at the present time should have Cabinet status. Traditionally, Cabinet jobs have not been established until after the need appeared. We started out with only four Cabinet members when the country was formed, and the number slowly increased. There has always been a definite need before a new one was created.

You may be doing a great deal of harm if you set this agency up too big and too vast at the start. The people who will run it may become too involved in the administrative aspects of the agency instead of doing the job itself.

I can tell you from my own experience it is pretty good to be unknown and small in the beginning, because then you can go ahead and get

the job done without others finding out what you are doing. When they find out what you are doing, they try to interfere and take charge.

Mr. KEATING. On the other hand, you can go too slow in this area.

Admiral RICKOVER. Well, presumably, the agency is going to have a committee to help it composed of people with the same good will as you have here at this meeting. They cannot do this job by themselves. If they are to do a good job they are going to have to depend on the congressional committee, that is their safety and their assurance—that is enough.

Mr. KEATING. You and I fundamentally differ about this point, so you cannot answer my question.

Admiral RICKOVER. Yes, sir.

Mr. KEATING. Then answer this question if you can: You said that in your opinion there perhaps were only 10 or 15 men—I think that is accurate——

Admiral RICKOVER. Some number like that.

Mr. KEATING. Some number like that who would be qualified to be the director of this agency, and you said you thought that man should come from Government. Why do you say from Government?

Admiral RICKOVER. I say from Government because you cannot take a man who has been in industry, with the philosophy he has developed, with the friendships he has made——

Mr. KEATING. We have covered industry. I am talking about science, public administration.

The CHAIRMAN. Education.

Mr. KEATING. Education, or some other field.

Admiral RICKOVER. You could if the man were good and he had made up his mind to stay on that job to his dying day. This is really the criteria. You cannot get a good job done in these fields unless the man feels he is to be there forever—and acts accordingly. I would like to see a politician——

Mr. KEATING. We have the shortest tenure of anyone.

Admiral RICKOVER. Well, this is a good chance for one of you to get a good job.

And I used "politician" in the sense that it is good to have a man who has learned how to get along with people, who can size them up, and who understands how to get things done. If you have a good politician and he made up his mind to stick around, he could do a good job.

Mr. KEATING. Well, you got a good thought there. We will have to pass that along to the President.

Admiral RICKOVER. Are you thinking about it?

Mr. KEATING. I want to deal for a moment with your statement to Mr. O'Brien in answer to, as he put it, a blunt question, and you gave a blunt answer. That is true all through the Armed Forces, is it not?

Admiral RICKOVER. Yes, that is true in the Armed Forces. Normally the people in the Armed Forces will put in a 2 or 3 year tour of duty.

I can tell you this categorically: It would have been absolutely impossible for me or the other people in my organization ever to have come near doing our job with that system of rotation. It cannot be done; we are just fooling ourselves to believe otherwise. This is why I chided Mr. McCormack about his 1954 report. He did a darn good

job in those hearings. But then he stopped, and this is what I have against him—he did not follow through.

The CHAIRMAN. How do you know we stopped?

Admiral RICKOVER. Well, I have not seen any results.

The CHAIRMAN. Just a minute. Ninety-five percent of the recommendations could be accomplished administratively.

Admiral RICKOVER. Yes; sir; they can.

The CHAIRMAN. All right, now, you had better go over to the Defense Department and ask them why they did not farm it out.

Admiral RICKOVER. I am sure you have more influence with the Defense Department than I have.

The CHAIRMAN. I am like yourself; I am an unrestricted individual. I do not have much influence anywhere, my friend.

Admiral RICKOVER. That's for the newspapers.

The CHAIRMAN. You would make a good politician.

If what you say is true about the report——

Admiral RICKOVER. I think you should have followed up on it.

The CHAIRMAN. Ninety-five percent, at least, of our recommendations could be carried out administratively. Legislation is not required under the organic act, and they could have been put into operation, or any part of them could have been put into operation.

Admiral RICKOVER. I think the only people who have read your report are you and I—and the stenographer who typed it.

The CHAIRMAN. Well, there may be a lot of truth to that. And I have a higher opinion of the hearings and the report after Dr. Killian was appointed as scientific adviser to the President, because there are over 22 pages of his testimony in the report, and it gave a little idea as to his thinking.

Admiral RICKOVER. I would like to compliment you, sir. You did a good job there.

The CHAIRMAN. I do not mind being chided when I am to blame, but your chiding should go right over to that department of which you are a very important part.

Admiral RICKOVER. Yes, sir; but you have greater facility in doing the chiding than I have.

The CHAIRMAN. Well, that is a question of fact.

Admiral RICKOVER. I will bet on you. I would vote for you on that.

The CHAIRMAN. I will say this much. You are one of the men who has been able to have a breakthrough where given responsibility and carried it out.

Admiral RICKOVER. I was never given any responsibility; I took it. That is what you want to achieve—to get people to assume responsibility.

The CHAIRMAN. You took it?

Admiral RICKOVER. I am not saying this in any joking manner either. No one has any final responsibility in the Defense Department.

The CHAIRMAN. I am informed by reliable sources, and this is with the most profound feeling of respect I have. I never met you until a few weeks ago in executive session—and today—that I can remember. I do not know why, but I was always on your side when there was a battle in Congress.

Admiral RICKOVER. Yes, sir; I know you were.

The CHAIRMAN. But they tell me that the laboratories you run and the functions you perform with those associated with you are about as efficient as can be humanly approximated.

Admiral RICKOVER. There is one way you can judge that efficiency. We are placing 100 percent of all our contracts today for the complete propulsion plants for our nuclear submarines on lump sum competitive bidding, and we have built up industrial facilities to do that without the investment of 1 dollar of Government money.

The CHAIRMAN. But more than that, you have created a spirit of dedicated men and women who are associated with you, which is important. As a matter of fact, you are looking ahead 5 years, are you not, at least 5 years on young scientists and others coming into your organization?

Admiral RICKOVER. Yes, sir. I hire none but young people just out of college who have not yet been spoiled by industry. I would not hire any of you because you are too old and you have learned too many bad things. You do not have enough potential.

The CHAIRMAN. There still are a few good qualities among us.

Admiral RICKOVER. Well, there are. You give us money.

The CHAIRMAN. I will let you carry on from there, Mr. Keating.

Mr. KEATING. Admiral, I agree that it is necessary for longer tenure than ordinary for an Army or Navy officer in the type of work you are doing, and having served, as many others have, in the armed services, and being shifted from here to there, I realize the merit of what you say.

Are you advocating that principle throughout the armed services?

Admiral RICKOVER. Yes, I think we tend too much in the armed services to use the time of the people to train them so that they can do every possible job. We simply cannot do that anymore. Warfare has become too complicated.

Mr. KEATING. The argument the armed services give is that you need flexibility, that the Army or Navy officer must have a knowledge of other areas in order to be a good one.

Admiral RICKOVER. Yes, every naval officer is supposed to be able to become a good diplomat, but no diplomat can ever be a good naval officer. That is what you mean?

Mr. KEATING. In general, by a slight oversimplification.

Admiral RICKOVER. When I was younger I used to believe, too, that if you were a member of the military, you had to train yourself to do every sort of a job in the world. But it is no longer possible to do this in the military any more than it is in industry or in Congress. You get on one or two committees and you stay on them a long time. That is why you are able to do a good job.

Aren't you just as smart as the military? You probably think you are smarter, and you probably are.

Mr. KEATING. Some of us.

Admiral RICKOVER. But in this age of specialization, you cannot do everything, and that is one of the things that is wrong.

During the time I have been in my job there have been six Secretaries of the Navy, six Chiefs of Naval Operations, six Chiefs of the Bureau of Ships. As each new one comes in, I must start from scratch going over and over the same things. You cannot blame them. They have got to find out, because they are responsible for making the decisions.

But pretty soon I get to the point where I am doing nothing but explaining, and when does the work then get done?

That is the dilemma one gets into. None of us mind having people with a real purpose come in to learn what we are doing.

The last time I testified I invited the members of this committee to see some of our nuclear ship models. I would like to have the opportunity to explain them to you because you have an important function. You have not seen the models because you do not have the time. But I believe it would be of help to you; it would give you a better understanding of some of our advanced technology.

Mr. KEATING. You are very frank, and there are many respects in which I know you are telling us correctly.

Admiral RICKOVER. We could do our job much faster if we did not have uninformed interference. This is one of the things you might try to do for this agency you are setting up: You might try from an accounting standpoint, to be a little more liberal on the expenditures of small sums of money. Don't let their time be taken up with trivia when they are trying to conquer space.

Mr. KEATING. I want to ask you two questions about this specific legislation.

I gather from the way you talked about it that the way you envisioned this agency—and you will correct me if I am wrong—is that you are in fundamental disagreement at the moment with section 6, which defines the functions of the agency in so far as subparagraph three is concerned, where it gives this agency the authority "to acquire, to construct, to improve, to repair, to operate, and to maintain laboratories, research and testing sites, and facilities" and so on.

Admiral RICKOVER. No. sir. I am not in disagreement.

Mr. KEATING. You are not in disagreement?

Admiral RICKOVER. I was voicing a note of caution—that they be required to certify, when they request new facilities, that they cannot find suitable existing ones either in industry or in another agency of Government.

The way I like to run my job is to have a minimum of people at headquarters, to place the work out to the field and not build up a large staff at headquarters. This is what I mean. The agency must have authority to acquire facilities but it should be used sparingly. They must, of course, be able to come up with requests for appropriations to acquire facilities, but the committee should be very careful to ask: Why do you need this? Why do you not use existing facilities or people? Because if they start in doing everything themselves, they will be swamped with the administrative aspects of the job.

Mr. KEATING. That is the paragraph which gives them complete operating authority, and you would not deny them that; in the basic legislation?

Admiral RICKOVER. No, sir.

Mr. KEATING. But you would caution the Appropriations Committee to watch that very closely?

Admiral RICKOVER. I would include a clause in the legislation that they try, to the maximum extent possible, to use existing facilities and people. It is not necessary for every Government agency to have its own empire.

Mr. KEATING. I think that is good advice.

Now, referring to this board, it is a 17-man board, and it does meet 4 times a year.

The CHAIRMAN. At least.

Mr. KEATING. At least four times a year. It is intended to be a temporary part-time group. Do I understand you to feel that it would be better not to have a part-time and to have a full-time board?

Admiral RICKOVER. I do not favor a large board, sir.

Mr. KEATING. Not that size?

Admiral RICKOVER. As you were asking that question, I was thinking about how the Russians go ahead with their large-scale projects, in which they admittedly have been able to reduce lead time. I am sure you will not find any board of 17 people meeting 4 times a year telling the man in charge what to do.

Mr. KEATING. They do not pay as much attention to boards there.

Admiral RICKOVER. I am certain of that. They pay more attention to results.

No, sir; I am opposed to this type of operation. I have seen a lot of it.

Ask the Atomic Energy Commission what impact their General Advisory Committee has had on the atomic energy program.

Mr. KEATING. How many are on the advisory committee?

Admiral RICKOVER. There are nine.

Mr. KEATING. Do you have an opinion on that?

Admiral RICKOVER. Yes, but I will not tell you.

Mr. KEATING. All right. We have the responsibility, and we believe we have, if responsibility exists anywhere, of framing legislation here. Do you think that there should be something in between, but that there should be a 3- or 5-man full-time commission to deal with the director—something in between?

Admiral RICKOVER. No, sir.

Mr. KEATING. What kind of a setup would you think right?

Admiral RICKOVER. I would have a director. I would provide for 1 or 2 committees to advise him, provided for in the law. You can even have the advisory committees submit their reports to Congress. This is done by the General Advisory Committee to the Atomic Energy Commission. They submit a report which also goes to the congressional committee.

Mr. KEATING. Of course, this board envisioned here is, I guess, something called an advisory board but—no, it is called the National Aeronautics and Space Board, and they have certain respects in which they circumscribe the director, and it says that the board must be consulted as to certain matters.

Admiral RICKOVER. Look at it from a practical standpoint. Here is this poor man trying to do a job with 17 experts who have their own opinions. If he wants to get his job done, he somehow or other has to satisfy this group of 17. Just like when a Congressman calls at my office and wants something, we act a little differently toward him, particularly if he is on the Appropriations Committee, than we do to somebody else.

The problem is to get the proper man and not hog tie him with a board. I would have one or more small advisory boards, but not a board sitting over him and telling him what to do.

The CHAIRMAN. That observation shows you are very practical, Admiral.

Admiral RICKOVER. Thank you, sir.

The CHAIRMAN. So you take into consideration position, friendships, and other things, about which I asked a question or two earlier.

Admiral RICKOVER. Don't forget, some of this politics rubs off, even on witnesses.

Mr. KEATING. He did not say he did anything, he just said he listened more carefully.

You have been very helpful. What troubles me is that we must not hamstring this director.

Admiral RICKOVER. I think you would practically hamstring him this way.

Mr. KEATING. And you are familiar with the language of this bill?

Admiral RICKOVER. Yes, sir, I am familiar with it.

Mr. KEATING. You think that particular element should be changed in some way.

Admiral RICKOVER. Yes, sir.

Mr. KEATING. Thank you.

Admiral RICKOVER. You might have 1 or 2 committees with a small number of people. I just cannot see a 17-man committee getting together 4 times a year and settling the affairs of an agency.

Mr. KEATING. I have strong reservations about that being the right way to go about it. I agree with you.

The CHAIRMAN. Of course, you have to consider the historical facts in connection with the NACA. As you know, it was set up in the early 1900's and did not have much experience, and the field was limited. The Board then created was above the Director as it is now.

Admiral RICKOVER. Yes, sir.

The CHAIRMAN. This bill changes it to where the Director then becomes the head of the agency and the Board is to advise.

Admiral RICKOVER. But you still have not made this clear line of division. What I am really advocating is putting a director in charge.

The CHAIRMAN. I recognize that, but I wanted to have the historical aspects in the record and the fact that now the Board is the head of the agency in the organization setup. It will not be under the proposal now before the committee.

Admiral RICKOVER. The Boards do not really run these agencies. They cannot.

It is just like the Board of Visitors at a service academy. The Board spends 4 or 5 days looking around. Then it has to depend a great deal on an Academy official who has been working on the project for months, to assist them with the report. You just cannot casually get into technically complicated matters and have a real technical influence on them. It cannot be done. The Director could of course use the Board as a means to help him, because when he gets these 17 members to sign something, it proves he has full scientific backing. This method is not unknown in Washington.

Sometimes administrators want boards for this purpose.

Mr. KEATING. You see, Admiral, the point I am making is that this says that the Board shall be consulted by the Director as to 4 specific matters, and those 4 matters are, for example, like any major change in policy.

Now, those are very important matters, and the Director must consult with the Board. I am not sure, but I think that might have the effect of hamstringing him, as you say.

Admiral RICKOVER. Your legislation should provide that he has to keep the congressional committee informed of what is going on. As I said previously, I would much rather have a congressional committee which puts in a good deal of time than any part-time board. So my recommendation would be to have a Director, have 1 or 2 small advisory boards, have the reports of the boards also go to the congressional committee, but do not set the boards up to have mandatory authority over the Director.

I would do still another thing: I would make absolutely certain that Congress gets full access to information from this new agency it is setting up. That is, this agency should be a true creature of Congress. You must make sure that this creature you are setting up and supporting will legislatively and financially be respective to your ideas and give you all the information you need to carry on your own duties.

Do you understand what I mean?

Mr. KEATING. Yes.

Admiral RICKOVER. I would insert that in the law.

Mr. KEATING. You would have them make a report to the Congress or at least to this committee?

Admiral RICKOVER. Yes. That is done by all commissions.

I would go further than that. I would spell out in the legislation that it is a creature of Congress.

I am discussing now the involved problem between the legislative an dthe executive about access to information. I would provide in the law that this new agency, set up by you, keeps you fully and currently informed, that it is your right to get all the information you ask of it, that it is not a privilege for Congress to get this information. Because you cannot do your job properly if you do not get all this information.

I do not see any reason for any fight between the executive and the legislative in a matter like that. I do not believe the separation of the three branches of government was ever intended to mean that Congress could not get all the information it needs in order to do its business.

Mr. KEATING. You have shown a very friendly attitude toward Congress today.

Admiral RICKOVER. Members of Congress are the only ones who have to run for office. The rest of us are all appointed.

Mr. KEATING. We have to run every 2 years.

Admiral RICKOVER. I understand. You are the only ones who stick your necks out. I don't stick mine out every 2 years; you have to.

The CHAIRMAN. Are there further questions?

Mr. Feldman.

Mr. FELDMAN. I think you indicated that the Government had a monopoly on people who might be qualified to fill the position of director of such an organization.

Let me preface what I am going to ask you by telling you that in World War I we had a relatively difficult job to marshal industry into a cooperative effort for the first time in history and create a large productive capacity. And the man who did that was a man taken from industry. I am referring now to Bernard Baruch.

Would you say we might be able to find somebody in industry just as dedicated as he was in order to do a corresponding job?

Admiral RICKOVER. You are asking several questions at one time. Let me see if I can answer them.

I do not think the analogy is entirely correct. Production is something that involves the use of factories and machines and the marshaling of facilities. An outstanding job was done, and it certainly was wise to place an industrialist in charge. But that was in wartime. The rules you use and the things you can do in wartime and the things that motivate people in wartime are quite different than those in peacetime.

The people who came in then knew they had to do a production job, they knew what the job was, they had the necessary priority, and they had everybody in the country solidly behind them.

But here you are marshaling brains and that is far more difficult than pushing production. I do not say that it has to be a man from government. It could be a man from a university. It could be a politician.

But I am afraid of a businessman coming in for a couple of years' tour of duty. I am afraid that just because he is an expert in running a business organization this does not necessarily make him an expert in doing a large-scale research and development job. The values, the objectives, and the methods in business are different than they are in government.

Some people in industry, for example, have reputations in research and development that are synthetic reputations. They are built up by advertising and by propaganda because it pays the company to do that. It casts glory on the entire organization.

Mr. FELDMAN. That could happen in any field, could it not, Admiral?

Admiral RICKOVER. You are really asking me this question: Who are the best people in our country today? Where do we go to get them?

I said government because there are a number of people in government who could do this. I said it does not make any difference whether they are military or civilian, it depends on their knowledge and ability to run things, and on an understanding of the aims of government.

Mr. FELDMAN. But you would not preclude a man from industry if you felt he had great managerial ability?

Admiral RICKOVER. No, I would not.

Mr. FELDMAN. In fact, a man from some of our large industrial concerns might be just the kind of a person who could cut through red tape.

Admiral RICKOVER. It is quite possible. I would not preclude anyone, sir. I tried to indicate I thought that on the average you would probably get a better job done by a man from government.

Mr. FELDMAN. I just wanted to clear up one or two things about the bill.

I believe, in your answer to a question by Congressman Brooks, that you stated it was necessary to set up a strong military liaison in the legislation itself.

Admiral RICKOVER. Yes, sir.

Mr. FELDMAN. Would you also set up a corresponding liaison with the AEC, which has a space program under way at the moment, or would you have the new agency take over the AEC facilities in this connection?

Admiral RICKOVER. The way I would handle it, I would let the AEC or any other agency keep on doing the work they do and not just try to take it over, but I would consider them as a contractor. Later on, if it became advisable or necessary to do so I might take the project over. But you do not have to have a liaison group with everybody with whom you do business. You might just as properly have liaison with U. S. Steel just because you use their steel, and you certainly do not need that.

If the AEC has facilities and people that can do a job, use them. If they do not do a good job, take it over, or go somewhere else, or do it yourself.

But the smartest thing that the man at the head of the new agency could do would be to take on the minimum number of technical responsibilities himself, and try to get other people to do as much as possible for him.

Mr. FELDMAN. If you need a liaison for the military, do you not need it for AEC?

Admiral RICKOVER. Not necessarily. The reason you need a liaison for the military is because you are planning to set it up as a civilian group, and the AEC is already a civilian group. There are military implications in this, and you want to make sure that the military are taken care of, and so you set up a military liaison committee to give the military this opportunity.

Mr. FELDMAN. How about the AEC—their facilities are equally important?

Admiral RICKOVER. The AEC is already a civilian agency. On that basis you would need a liaison group between any two civilian agencies in government. You have to presume that in the normal conduct of government business the people will deal with each other. The reason to make an exception in the case of the military is because it is concerned with defense. Also the military has been doing this work. In this way you tend to tie this whole thing together.

The Chairman. I take it you mean there should be cooperation between the AEC and all agencies?

Admiral RICKOVER. There is supposed to be anyway. There should be.

The CHAIRMAN. Is that what you had in mind, Mr. Feldman?

Admiral RICKOVER. If you start having too many of these liaison committees you will get into the same situation as with too many boards.

Mr. FELDMAN. Not necessarily. Could you set up one liaison operation to include both the military and the AEC, because of the AEC functions in this area? That might take care of both organizations.

Admiral RICKOVER. There is supposed to be liaison all the time between all branches of Government. You must assume that the Director of the new agency will arrange for necessary liaison whenever this is necessary.

Mr. FELDMAN. I am not talking about all branches of Government. All branches of Government are not concerned with space. The AEC is concerned with space—at least one branch of the AEC.

Admiral RICKOVER. They are only concerned with space to the extent that they are developing propulsion. The agency will have to go to other organizations besides the AEC to do things for them.

Well, you asked my opinion. Here it is.

Mr. FELDMAN. Admiral, we had some testimony from another witness stating that if we had a hundred scientists doing research we might get 10 good ideas as a yield from the work they were doing, or the research they were doing, and if we had a thousand it would stand to reason we might have a hundred ideas coming from the group.

You also stated previously that the Russians had this program of training a great number of astronomers and a great number of scientists, and very successfully. How do you reconcile that with what you had to say about having a small group of scientists? If we do not need to have a large number of scientists, why train them?

Admiral RICKOVER. I think you misunderstood me. What I meant to say was that the headquarters organization should not become too large, it should not have a large number of people, but should instead try as much as possible to have the talent in the external organizations. Otherwise the headquarters organization will become completely involved with administration, to the neglect of its real job.

Does that clear it up, sir?

Mr. FELDMAN. That does.

The CHAIRMAN. Are there further questions?

Admiral, we appreciate very much your appearance, and you have been most helpful. On behalf of myself and the other members of the committee, I extend to you our sincere thanks.

Admiral RICKOVER. I appreciate having been permitted to testify before your committee, sir.

The CHAIRMAN. You keep in mind what I said about editing your testimony.

Admiral RICKOVER. And adding to it.

The CHAIRMAN. Yes.

We will now recess and meet again at 2: 30.

(Whereupon, at 1 p. m., the committee recessed, to reconvene at 2: 30 p. m. of the same day.)

AFTER RECESS

(The committee reconvened at 2: 30 p. m., Representative John W. McCormack presiding.)

The CHAIRMAN. The committee will be in order.

We are very happy to have with us the next witness, Rear Adm. J. T. Hayward, Assistant Chief of Naval Operations for Research and Development.

Have you a prepared statement, Admiral?

Admiral HAYWARD. Yes, Mr. Chairman, I do have.

The CHAIRMAN. All right.

STATEMENT OF JOHN T. HAYWARD,[8] REAR ADMIRAL, ASSISTANT CHIEF OF NAVAL OPERATIONS (RESEARCH AND DEVELOPMENT)

Admiral HAYWARD. Mr. Chairman, members of the House select committee, I am Rear Adm. John T. Hayward, Assistant Chief of Naval Operations, Research and Development. It is the purpose of my statement today to—

(*a*) State the Navy's interest in space programs;

(*b*) Comment on the organization of a national space agency, and

(*c*) Comment on the problems connected with outer space.

During the past 6 months a great many words have been written and spoken concerning space exploration, space programs, and organizations to handle space problems. Among all these words there has emerged an implication, in certain areas, that the Navy is not interested in a space or satellite program.

This is absolutely untrue. This was particularly the case when I was having all the trouble with the Vanguard situation.

The Navy most definitely is interested in and desires active participation in a national satellite and space program. We consider that our interest would be best served by, and within, a broad program for space vehicle research and development of national scope and character.

The national space program should consist of both an integrated long-range effort establishing fundamental requirements and an immediate program utilizing existing and presently planned flight vehicles as a necessary part of the concerted national drive toward the exploration and exploitation of space.

It is the Navy's policy to support a national space program which will serve both military and scientific needs. The Navy has the strength, experience, and proven competence to make a major contribution to a national space program.

The following list highlights certain areas of Navy experience which are particularly applicable:

(*a*) Research and development experience in rocket and ramjet propulsion, particularly the development and application of solid and liquid propellent engines.

---

[8] Admiral Hayward is Assistant Chief of Naval Operations (Research and Development) He was born in New York City on November 16, 1908. He graduated from the United States Naval Academy in 1930

His early service included sea duty on the U S S *Richmond* He was designated naval aviator on September 13, 1932, and subsequently served in carrier-based Scouting Squadron 1, Patrol Squadron 2, based on Coco Solo, C Z ; the aviation unit of the cruiser *Philadelphia;* and as senior aviator of the cruiser *Phoenix*.

Prior to and following the outbreak of World War II he served as assistant chief engineer (for instruments) at the naval aircraft factory, Philadelphia, and while so assigned had duty in 1940–41 as United States naval observer with the Royal Air Force. From December 1942 until March 1943 he had command of Headquarters Squadron, Fleet Air Wing 2, on the west coast He commissioned, then commanded, Bombing Squadron 106 in 1943–44

In June 1944 he became experimental officer at the naval ordnance test station, Inyokern, Calif, where he worked on all phases of rocket development and the development of, and study of destruction caused by, the atom bomb From July to December 1948 he was Director of Plans and Operations for the Armed Forces, Sandia Base, Albuquerque, N Mex, concerned with the use of atomic weapons and integration of military requirements with the Los Alamos Scientific Laboratory.

He was in command of Composite Squadron 5 from December 1948 until June 1951. This was followed by a tour of duty with the Atomic Energy Commission (Military Application Division), a year at sea in command of the carrier escort vessel *Point Cruz;* and command of the Naval Ordnance Laboratory from June 1954 to January 1956. He commanded the giant aircraft carrier U S S *Franklin D Roosevelt* from February 1956 until January 1957, when he became special assistant to the Director, Strategic Plans Division, Office of the Chief of Naval Operations In July 1957 he was ordered to assume the duties of Assistant Chief of Naval Operations (Research and Development).

Admiral Hayward has received many decorations including the Silver Star Medal, Legion of Merit, Distinguished Flying Cross, and the Purple Heart.

(*b*) Upper atmospheric research.

(*c*) Navy space flight research programs of the Office of Naval Research and the Bureau of Aeronautics.

(*d*) Knowledge and experience gained in the successful Vanguard scientific program.

(*e*) Aeromedical and space medical research; particularly the closed-space environmental physiology and psychology; and human stress tolerances.

(*f*) Radiation research.

The foregoing list is not all inclusive. It should be noted that 72 percent of the surface over which earth satellites or manned space vehicles will fly is covered with water. This immediately indicates a requirement for a Navy contribution to the national program in the form of strategically placed ships properly instrumented and equipped to perform such essential functions as mobile launching, tracking, data collection and analysis, control, and recovery. This important operation can be conducted under conditions of maximum security and without infringing the sovereignty of other nations.

The Navy has actively participated in research and development studies and experimental developments related to space travel since 1942. In fact much of the information gathered had a direct bearing on the establishment of the feasibility of creating a manmade earth satellite. In 1945 the Navy proposed that a satellite project be initiated.

This project was formulated on the basis that we could build rockets with sufficient performance which, when combined in clusters and stages, would be able to place a small payload into orbit. This proposal was finally rejected by the Committee on Guided Missiles of the Research and Development Board as not having sufficient military requirement.

In June of 1954 the Navy, with the cooperation and support of the Army, established a satellite program known as Project Orbiter.

This program was implemented, developed some component parts and had as its goal the placement of a series of satellites into an earth orbit, the first of which was to be a 5-pound sphere at 200 miles. However, in July of 1955, Project Orbiter was replaced by Project Vanguard as a result of a technical evaluation by the Department of Defense. Thus, Vanguard became our primary space satellite program.

Project Vanguard must certainly be considered as an unqualified success. Starting from scratch in October of 1955, a highly successful flight was made on March 17, 1958, which resulted in a satellite being placed into orbit. This performance is unparalleled in the history of United States rocketry.

The foregoing statements are made as evidence of the Navy's interest and successful history in space flight and earth satellites.

We believe that satellites and manned space vehicles can make notable and in some cases unique contributions to some of the Navy's standing requirements. Some of these requirements have to do with geodesy, navigation, weather forecasting, and communications; others are of a more classified nature. We fully recognize that our sister services have equally firm and similar requirements, thus it is inescapable that overall military requirements can best be met through a national program.

It is the Navy's desire and policy to take an active part in that program.

The prime function of the space agency, to be established by Congress, is development of a comprehensive program of research in space sciences and a national space program. We have an immediate and urgent need for a program that will serve both military and scientific needs. The legislative proposal to take over and enlarge the present NACA into a new agency called the National Aeronautics and Space Agency (NASA), is, in my opinion, the logical choice. There are several minor comments on the legislative draft as now written that the Navy feels would improve and clarify the functions of the NASA and these comments will be forwarded through proper channels for consideration.

The NASA has been compared to the AEC as an example of organizational efficiency. While there may be certain comparable aspects, the NASA will have a more difficult organizational problem and this must be recognized. It is comparatively easy to delineate the areas of cognizance within the AEC, on the other hand space technology cuts across almost every known area of research and development, including, perhaps nuclear power.

It is emphasized that the agency proposed would have directive authority rather than advisory, it is therefore of great importance that the delineation between civilian and military interests be made clearly and justly to avoid jurisdictional disputes.

Through the centuries military progress has been achieved by research with the military working side by side with the scientists. Each side has benefited from this relationship.

As the President's Science Advisory Committee reported—

> in fact it has been the military quest for ultralong-range rockets that has provided man with new machinery so powerful that it can readily put satellites in orbit * * * In this way, what was at first a purely military enterprise has opened up an exciting era of exploration that few men, over a decade ago, dreamed would come in this century.

Although there are some military applications in satellites that are readily recognizable, other applications are not. However, there is little doubt that future developments in space technology will open new possibilities.

We are aware that it is a military responsibility to assure that full advantage is taken of the military potential of space.

We must assure that space is not used to endanger our security, we must be prepared to use space to defend ourselves if that is the best method.

Consequently, the military and civilian aspects of outer space are inseparable.

Finally, gentlemen, a word of caution. The space agency must plan its program as a part of a balanced national effort in all science and technology—the correct balance of emphasis must be sought. The national space program should be treated sensibly as a most important but not the only important program in the Nation.

The timetable established by Dr. James Killian and his fellow scientist is most appropriate—"early" "later" "still later" and "much later still" and within this timetable, we must continue to stand ready to cope with any threat and carry out all missions assigned.

I would like to add to this statement by saying: In the space business one must always remember the definition of the national strategy of the country, which is the use by a country of the political, economic, psychological, and military forces in peace as well as war to attain the national objectives.

It was quite obvious that the Soviet recognized this definition of strategy, for the reason last year when they put up the sputnik, this was a marvelous example of the psychological forces of the country to further their objectives.

We must never forget this definition of "strategy," because it has a great deal to do with the space agency and the fact that anything we do in it does have a psychological effect on the rest of the world, and it helps us to obtain our objectives.

The CHAIRMAN. In view of the fact that Mr. Fulton is leaving shortly for Pittsburgh, without objection the Chair will recognize Mr. Fulton to ask a few questions.

Mr. FULTON. I want to compliment highly, Admiral Hayward as the head of naval research and development for his excellent service to our country in his capacity.

Also I want to compliment Admiral Hayward and his associates for their part in the two electronics breakthroughs that are amazing in the broad new fields that are open.

Before I ask the two questions, I would like to point out that there is no description of methods, calendar, no designation of programs by name, place, service, or type of equipment.

The questions are these: On current research developments, do we in the United States have it within our power soon to monitor the whole world, including countries behind the Iron Curtain, through electronic processes of ion emission.

Admiral HAYWARD. The answer is "Yes."

Mr. FULTON. The second question is this: Don't we in the United States have the capability through electronic means soon to use the moon as a means of reconnaissance so that we don't have to wait for production of satellites in orbit or a moon shot or a landing on the moon.

Admiral HAYWARD. The answer is "Yes."

Mr. FULTON. Thank you very much. That is all.

The CHAIRMAN. Would you elaborate on the answers to both these questions?

Admiral HAYWARD. Mr. Chairman, I could. It would have to be in executive session, however.

Mr. FULTON. Those questions have been cleared by you in that particular form and I have read the questions to be exact.

Admiral HAYWARD. Yes.

The CHAIRMAN. I think after the hearing is over we ought to have a brief executive session. Is that agreeable to the members?

(Unanimous assent.)

The CHAIRMAN. Mr. O'Brien?

Mr. O'BRIEN. I would like to reserve my time.

The CHAIRMAN. Mr. Natcher?

Mr. NATCHER. Not at this time.

The CHAIRMAN. Mr. Metcalf?

Mr. METCALF. Thank you, Mr. Chairman.

I am pleased, Admiral, that you have made a recommendation as to how this organization is to be set up, and I say that the NASA is a logical choice. That is one of the things that concerns this committee. When you say it is emphasized that the proposed agency would have directive authority rather than advisory, I am assuming you are referring to section 6 (a) paragraph 2 of the President's proposed bill which says that the "functions of agencies should be to plan, direct, and conduct scientific studies," and so forth.

But the directive authority, as I understand it, would be in the hands of the director rather than in the hands of the board created, is that correct?

Admiral HAYWARD. That is correct, sir. I have looked at this legislation quite closely, checked it with the President's message and compared it to the legislation establishing the NACA.

The Director of NASA is to be appointed by the President by and with the advice of the Senate. Whereas, today, the NACA Director is appointed by the Chairman of the Committee, which is a fundamental difference. The Director of NASA should have the authority, and he should have the responsibility.

The NACA today does not normally buy vehicles. The Navy and the Air Force in the X-15 program procure the vehicles for the NACA. There is a broad responsibility proposed for the NASA agency that goes further than what the NACA has today.

I don't think this is wrong at all. There is a great sense of urgency in this business and it is not limited to just the space business. It goes into technical training and research and development. When you see what the Russians are doing today, it upsets me no end, because the effort that the Russians are making is something terrific and every American should know that it is not going to be just 1 year or 10 years, but a long, long time.

And we will have to make a national effort of this kind across the board, not just space.

The Russians make their technical decisions at a very high level. One of the things that worries me, and I have been in the research and development business for a long time, is that we don't have very many technical decisions made at a high level.

Let me give you a good example. The National Presidium of the Soviet, which is the cabinet level, sits opposite the National Academy of Soviet Science. Back in the 1940s—1945, 1946—it was at this level that the Soviet decided to go to the ballistics missiles field. Now, in our country, such decisions are made at a much too low level. The Department of Defense, and I am in the military of course, makes such decisions and this is too low a level. I feel that we have to have competent technical people at the highest level to sit in on these basic research decisions.

I would like to see the very able Dr. Killian, let me say, legalized; and his authority defined. When we look outside the Department of Defense today, we see the National Science Foundation, the Atomic Energy Commission, the Bureau of Standards, and now, perhaps, the NASA. And I feel that one of the things that should go along with this legislation—or maybe it should be separate—would be something that would tie all of these technical agencies together in the Government under a competent technical man; if you want to call him "Secretary of Science,"—that is fine.

This "Secretary of Science" should sit at the level of the National Security Council. As an example, look back over the history of the Vanguard.

Now, I am not belaboring past decisions. And of course I could have even a shorter tour of duty than Admiral Rickover was talking about if I say the wrong thing.

But that decision that we were not interested in the Vanguard, that Vanguard was going to be the scientific IGY satellite, and it was not to interfere with the missile program—what technical people, what competent real scientists sat at that level and made that decision?

And in this meeting he showed you, well, maybe we didn't understand the psychological side of the national strategy.

So, I am all for putting competent technical people at as high a level in my Government as I can. The National Presidium of the Soviet, 60 percent are graduate engineers.

Look in Congress. They are all lawyers, or practically all. Maybe we have some chemists. I don't know. But they are not many. And you are having to make decisions on technical programs that involve our entire future.

So I feel very strongly that we should do something along this line. This is good. This is a step in the right direction.

Mr. METCALF. Perhaps you feel we are not putting the director high enough in the machinery of Government in creating this NASA. Maybe he should be a secretary in the President's Cabinet.

Admiral HAYWARD. That is right. Maybe he should be the secretary of science. When you do this, you should also bring in the other physical signs of the scientific parts of the Government.

Why aren't they tied together? You have the Bureau of Standards. You have the AEC. You have all of these agencies. I was with the Manhattan District when we—the AEC came into being. Now, the AEC has had a very fine and excellent history of good basic research. They do an awful lot in the physical science business that has very little to do in some cases with the atom as such.

I feel that we have to give due recognition to the technical side of life at the highest level in our Government.

In our Government we don't have that today. When you look at the Russian system, the Russian effort, it is surprising to me that our people can relax one moment. Now we have a couple of satellites in orbit, everything is fine, we will try to go back to life as it was. But life will never be the same again.

While I agree with Admiral Rickover that the research side of the house doesn't cost much money, this is going to cost terrific effort. It is going to go all the way down to the educational side and across the whole life of the American. And we have to realize it.

I think it is your duty as Representatives of the people to get it across to the people, that it is not something that will go away with wishful thinking. We just can't buy another car this year or something of this kind. So I am very strong for putting the technical people at the highest level I can, the competent technical people.

It is a very strange thing. When sputnik went up and everything was confused I made the same proposal that you gentlemen have gotten legislation for now And I was slapped down pretty hard.

Mr. METCALF. Now, it is your idea that this Director who would be a technical man, would be the person with whom the ultimate decisions would rest, rather than the Board.

Admiral HAYWARD. Definitely. If he has the responsibility, he has to have the authority.

I think that you can make him responsible, and give him the authority. Of course if he doesn't do his job, you fire him.

Mr. METCALF. You want the responsibility for this program placed as high in the Government as possible, and in the hands of one man who is technically trained?

Admiral HAYWARD. That is correct.

Mr. METCALF. I just wanted to clarify my ideas of your recommendations, because I respect your experience, Admiral. And thank you for that.

I assume that some of these comments and suggestions that you say will improve and clarify the functions are going to include technical changes in the legislation?

Admiral HAYWARD. Yes, sir. I have a complete list, chapter and verse, of what the differences are and what we feel would help this legislation or make it more effective to do the job.

Mr. METCALF. Are you satisfied that this legislation gives adequate liaison and attention to the needs of the Navy?

Admiral HAYWARD. Well, once again, we are for a national space agency.

I think you should have more people from the Department of Defense. I don't hold that it has to be Navy, Army, and Air Force. One representative from the Department of Defense out of 17 is not enough. Just as a matter of record, the NACA, for instance, consists of 17 people appointed by the President today. Two are from the Air Force. Two are from the Navy. Two are from the CAA. One is from the Smithsonian. One is from the Weather Bureau. One is the Bureau of Standards. And then we have—well, a total of 10 Government and 7 civilians.

The Chairman is elected by the Committee, the President approves the 5-year term.

Now, under this proposed legislation, you do not have a stipulated quota from the services, and so the composition of the board is not guaranteed to enhance the collaboration with the services as recommended in the President's message.

The CHAIRMAN. What is that you said, Admiral?

Admiral HAYWARD. I was saying that as the legislation stands today, the composition of this NASA Board is not such as to guarantee collaboration with the services as recommended in the President's message.

I feel that it could be strengthened and that the Department of Defense should have more than one representative.

Mr. METCALF. The suggestion you have would include recommendations that you are making, so that there will be cooperation with the services in accordance with the President's message.

Admiral HAYWARD. Yes.

Of course, this morning the recommendation about the military liaison committee was a good one, that came from the Atomic Energy Commission Act.

That has worked very well, and there is no reason why it should not be carried to this Agency.

I think the setup with the Atomic Energy Commission is a good one. The Atomic Energy Commission is responsive to military requirements, we get in on all of the programs, and we help them.

I think that the military relationship you want with this Space Agency is similar to what you have with the AEC today.

Now, if you had this Secretary of Science, or whatever you call him, you could use the present military liaison committee that exists on the statute with the Atomic Energy Commission to be the military liaison committee with all of the science agencies outside the Department of Defense. There is no reason why this could not be done at all.

And it would be effective if we had an Assistant Secretary of Defense for Atomic Energy matters, then he could be responsible for science matters. This would make sense and would save people, incidentally, too.

I think that the legislation would be improved in this manner.

Mr. METCALF. Thank you, Mr. Chairman.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. Do I understand, then, that you think that the proposal in the legislation concerning the 17-man board would be all right if there were some adjustment in the personnel?

Is that what you are saying?

Admiral HAYWARD. That is correct.

However, if you do what we are talking about in the military liaison committee, I would just leave the Board as it is.

Of course, having started with the Commission, 17 is an awful lot of people.

Mr. SISK. That was going to be my next question.

Admiral HAYWARD. That is too many for my money.

Mr. SISK. In view of the testimony we have had heretofore, that a so-called advisory board, which might meet four times or more per year, would not be the type of board, maybe, that we should have, and it is on that point that I want to find out what your thinking is.

Should we have a commission similar to the Atomic Energy Commission where you would have 5 full-time people or 4 full-time people, or whatever it might be?

Do you think this 17-man advisory board or 11-man advisory board or 9-man advisory board, as an advisory thing, is really good?

Admiral HAYWARD. I think that a 17-man advisory board is too many. I feel it should be brought down. And if you have any doubts about the authority of this Director, he is going to be a real powerful man in the scientific and technical field.

Maybe it would be better to go to the commission-type of thing, such as the AEC. My feeling is that we should tie all of these sciences together. However, this is difficult because you have labeled this legislation "space."

From a technical point of view, everything we do in research and development can have application to the AEC, the Bureau of Standards, the National Science Foundation, and this organization. I think they should be tied together.

I do not see why it is wrong to tie them together. I do not think it is too big a job. And if you are going to have this 17-man committee, maybe it could serve better as an advisory committee to all of the technical agencies, outside the Department of Defense, under the Secretary of Science. You have the Chairman of the Atomic Energy Commission; a Director for this NASA, a Director of the Bureau of Standards, and a boss man on the National Science Foundation.

Mr. SISK. For the moment, then, let's talk about this Director.

You feel that there should be a much greater recognition of this overall program or this agency or this director—if you will permit me to put it that way—that they should be upgraded insofar as Government is concerned.

Where in the scheme of things would you put this director. Would you put him under the direction of a commission, or would you make him more or less a czar? Would you put him at Cabinet level? Would you put him subject only to the President?

Just how would you fit him into the scheme of things, Admiral, at this moment?

Admiral HAYWARD. Well, I would do this: My statement about the Russians you might misinterpret a little. I say we need at our Cabinet level a competent technical man, and I call him, for want of better words, "the Secretary of Science."

This Director, NASA, would work for the Secretary of Science. Also the Chairman of the Atomic Energy Commission and the boss of the National Science Foundation would work for him.

The Secretary of Science could sit on the National Security Council, would participate in its functions and would make—well, it would be his job and responsibility to make basic decisions such as, in the case of Vanguard, he would have said, "Gentlemen, it does not make sense to do this."

Mr. SISK. I see. That is fine.

That is why I wanted to get your ideas.

In other words, you still feel that we need a high-ranking man at the Cabinet level, or a high-ranking man to whom the Director of this agency, as well as the other agencies, would report and to whom they would be subject?

Admiral HAYWARD. Yes, sir.

Mr. SISK. Let me ask you this, Admiral: Just how serious do you consider this problem to be, as a matter of priority?

Where would you place this whole program of space exploration? Do you think it is imperative, that it is an urgent program, and that we should put a lot of urgency back of it?

Admiral HAYWARD. It is a tremendously urgent program. However, I do not confine it just to space. I confine it to the challenge that the Soviets have made to us; it is a battle for men's minds, you must remember.

I have made a study into all of the research and development that the Soviets are doing in all of the basic sciences versus what we are doing, and we are just not doing half enough.

The Russians, for instance, lead the world in, of all things, oceanography. They lead the world in mathematics. The Russians are instilling an understanding and a respect for the scientific approach

in all of their people by the teaching of science and using the high percentage of classroom time for this sort of thing regardless of whether the student is going to be a ditch digger or whether he is going to be an engineer.

Now, we have made real good studies as to how and what they are doing. If you trace back all the way the 1920 and take, for example, one field, the electrification of the Soviets, which has had a high priority since 1920. This priority project has produced real results in educational programs, research facilities, and the creation of equipment and operating systems that meet their requirements.

Now, there is a very cute curve one could always draw. That is the kilowatts expended per person in any country versus the standard of living. In such a comparative curve, you will find that we stand No. 1, the actual energy used, per person, electrical energy. Now, you can pick a lot of other things too that would do the same thing. But the U. S. S. R. has recognized the importance of the, let me say, the research and development side of life.

As long ago as 1928 Tupelov and Sokovsky convinced Stalin that they had to change their system. Their system has changed completely from what ours is.

They had a centralized research and development agency in those days. When I say centralized, it was really centralized, as most communistic things were.

They convinced Stalin that they should decentralize. When they said "decentralize" they excluded policy decisions which would be made at the Academy of Science level; however, all of the other research and development institutes—and there are 775 of them—would have the responsibilities for the state of the art in whatever field they are working in, whether it is metallurgy, propulsion, aerodynamics, and that capitalistic decision was made in 1928.

They also have competition in designs and incentives. The results of people like Djurvich and Alushkin, who have won the Lenin prize 4 or 5 times; and that is $3,500 tax free in our country's money.

Of course, they do have a double incentive, as Admiral Rickover said; they either produce or get shot. If they produce, they are rewarded. If they do not, they get shot.

But their program is terrific. And the sense of urgency that I have is to do something in our country to really help the situation, to get it across to the people, and that it is one thing that, as I say, is going to be here the rest of my life.

Mr. SISK. Admiral, I appreciate very much your statement.

It seems to me, as I have listened to witness after witness, and particularly to your discussion here, that maybe some things in the past that I remember reading about as a child are coming true, that ultimately science and technology would rule the world. And apparently Russia, you feel, has awakened to that idea, and is putting it into effect.

We have felt that morality, justice, equity, and law would rule the world, and that maybe we are being forced to revise our thinking. Is that generally true, Admiral?

Admiral HAYWARD. That is true.

Of course, in the education field, I feel that—you know, everybody describes us as a democracy, and we are not a democracy; we are a republic, which is important.

I feel that in some of our education we have gone to the mediocre. Everybody has to get a high school diploma; nobody fails. In a lot of the schools you don't give the child the right to fail any more. If he fails, he will be back in that same grade next year. You have got too many people there now anyway. So you pass him.

I am sure as a father of five children I am well acquainted with that problem.

Mr. SISK. Just two or three questions, Admiral, in reference to your statement. I would like to ask this question: On the first page you mention a national drive toward the exploration and the exploitation of space.

Now, I assume that by exploitation, you have reference to, let us say, peacetime advantages that we might gain from space. Generally, is that what you had in mind there?

Admiral HAYWARD. That is correct.

Let's just take communications. We have lots of troubles with communications, and perhaps we can exploit space from this point of view. I firmly believe that the greatest advantages in the space business are purely scientific and learning more about our environment. The military application is very limited.

Mr. SISK. Now, over on page 2 under section (e) you referred to some of the problems and some of the things on which the Navy has done special research—in space medical research, and so on.

My question is: there is a limit to the stress that we can stand. To what extent do you feel that may limit our progress into space?

Admiral HAYWARD. Well, it can limit it terrifically.

Of course, you probably read of the submarine coming back from Europe submerged. If you have ever been on a submarine, you know that that is as close to being on a space ship as you can get. In the Polaris we estimate that the maximum time we can keep those people together in a place like that is about 60 days.

This may be your time limitation. Of course, the submarine is air conditioned. And we have hi-fi. And we have steak and eggs and movies. But, after a while even that gets bad.

So, this is why we have been very concerned with this. We have physical limitations right away in space flight. A man can only stand about 17 g. maximum without being killed, and if you exceed 9 g., it is pretty rough. So we do have physical limitations, and I am sure that some of our work is going to be limited by this.

Mr. SISK. Well, now, that brings up the question which I intended to ask. Now, you speak of 9 g. What is man going to have to stand? For example, I am sure you are aware that there has been some discussion around here the last few days about shooting or tossing a man into space.

Admiral HAYWARD. Yes.

Mr. SISK. And the importance of such an effort makes it more than a stunt. I think it is important. I disagree wholly with those who indicate that it was merely a stunt.

I wonder if you would comment with reference to the problems involved in getting a vehicle or capsule, or whatever a man may be enclosed in, developed so that he can stand the pressure of that shot.

Admiral HAYWARD. In looking at the proposals for space flight, including the 117L system, and some of the others, I feel that they are on pretty solid ground. As a matter of fact, they are limited to 9 g.

and well within the temperature limitations of man. They only go up to about 150 degrees and I think it is perfectly feasible to do this.

I feel that it is most important to follow from the X15 to the X15B, this is going to be your real approach to space. I am not about to volunteer for that first trip. Like Admiral Rickover said, I too have some candidates myself to go to the moon.

Mr. SISK. I yield to the gentleman from Kentucky.

Mr. NATCHER. One of the members of the other body recently called upon a group of physicists to state what they thought was wrong with our present program pertaining to our missile and space research programs. Are you acquainted with this record, Admiral?

Admiral HAYWARD. I am, yes, sir.

Mr. NATCHER. Briefly, I would like to read just 2 or 3 short paragraphs from this report. And I would like for you to comment on this portion that I read, Admiral.

> Recent startling developments have pointed out for all the world to see that we have fallen dangerously behind the Soviet Union in the development and exploitation of science in the national interests. This hard fact was not surprising to any one who has followed recent trends in the support and encouragement of Soviet science, including education, as opposed to our reluctance to place the proper emphasis on intellectual endeavors. Indeed the past few years have seen the emergence of an anti-intellectual climate and an atmosphere of smug self-satisfaction which places a premium on conformity and finds us woefully unprepared to meet the current challenge.
>
> The root of the difficulties in which we find ourselves is in the system that places the military in such close control of scientific research and development.

Now, Admiral, how do you feel about that statement?

Admiral HAYWARD. I will give you a speech on it.

Mr. NATCHER. You go right ahead.

Admiral HAYWARD. I will answer that by saying I do not know whether anybody on the committee can answer this question as to Who was the first American Nobel prizewinner in physics? I wonder if they know? Do you know who he was?

Mr. NATCHER. No, it so happens I don't. Who was he?

Admiral HAYWARD. He was a naval officer. Michaelson was his name. He made the first measurements of the velocity of light. The National Academy of Science was founded in the United States at the instance of the Navy. We had people all the way back to Bushnell who made the first submarine. You had my friend, Admiral Rickover, before you this morning.

Well, let me tell you my own history. I started in the Navy as a sailor. I did not graduate from high school. And I won the Lifesaving Medal, and President Coolidge appointed me to the Naval Academy.

Since graduating from the Naval Academy, I studied 3 years of theoretical physics, specializing in the Einstein theory at the University of Pennsylvania. I went to the University of New Mexico. I went to the California Institute of Technology. I went to Stanford. I went to the University of California.

I worked with Doctor Lauritson in the first propellant rockets. I worked for Doctor Oppenheimer. I was head of weapons research in the Military Applications Division of the Atomic Energy Commission.

I am not unusual in any way. We have very many military people who are very competent scientists. I am convinced in my own mind.

And I am sure—General Groves would agree with me—that we would not have had an atomic weapon today if it had not been for people like the late Admiral Parsons. I do not agree at all that the Navy has throttled research and development.

The Office of Naval Research was established in 1946 to fill the gap when the Office of Scientific Research and Development was closed after the war, and has given over 50 percent, or contributed money that is involved in over 50 percent, of the doctorates granted in the physical sciences in the United States of America since the end of World War II.

So, when they try and throw the cloak and say military is opposed to science and that we throttle research and development, I object very strenuously.

Mr. NATCHER. In other words, Admiral, you maintain that that statement is wrong?

Admiral HAYWARD. Yes.

Mr. NATCHER. Let me ask you about this group——

The CHAIRMAN. You are talking about the Navy?

Admiral HAYWARD. Yes, sir. The Navy has been a technical outfit ever since the country began.

The CHAIRMAN. Well, the Navy appreciated, I think, from the investigation we made in 1954, that we found the Navy was more streamlined, you might say, to the appreciation of the importance of research and development.

Admiral HAYWARD. Yes, sir.

I appeared before you, Mr. Chairman. I was running a laboratory for the Navy then.

The CHAIRMAN. You remember those hearings?

Admiral HAYWARD. Yes, sir, I do.

The CHAIRMAN. And they were very important hearings, although not followed much.

Admiral HAYWARD. I think, however, that the other services have some real fine technical people and have done a good job. And I do not buy the idea that the military throttles research and development.

I feel our record stands open and right today. For instance, in the Office of Naval Research, we have 1,500 contracts with nonprofit organizations, or universities, based upon purely scientific and research matters. We do not tell them what to do. They come in to us with their proposal. And I will say that in the world of science in the country today, I think the Office of Naval Research enjoys one of the best reputations in the United States.

Mr. NATCHER. Admiral, let me read you another statement. I imagine you will disagree with this statement:

> In the present age of advanced technology, the defense of a country depends increasingly upon the wealth of scientific principles available for creation of military devices by training and by delegated responsibility.
>
> The military people themselves cannot be expected properly to encourage and support fundamental scientific research. Military decisions must always be taken in terms of present defense and military strength of the immediate future. Long-range commitments to scientific research having no foreseeable application will always tend to be abused and sidetracked by the military directorate.

Do you disagree with that statement?

Admiral HAYWARD. Particularly, I disagree from the Navy's point of view.

Admittedly, Admiral Burke has to weigh the fact that he may have to go to war in Indonesia tomorrow. That is true. But the decision was made by the Navy when they formed the Office of Naval Research that we would commit at least 5 percent of the Navy budget to this area, to basic research and development. Since that time we have done that.

Now, this last fall, with the expenditure limitation and all of the program troubles we have had—which have been many—Admiral Burke made a decision that, as of the 1st of July this year, we would cut out everything but research and development. That was the last thing that was going to go.

So I feel in the Navy that we have an appreciation of basic research.

And admittedly I can see what they are pointing to; Dr. Bush and a lot of people have testified here about it. That operational requirements dictate what you do, and that if you do not have an operational requirement, you do not get something. But let me point out that the Polaris missile today, with the propellant that we have, is based on basic research that we did back in 1946 and 1947 in polymers when the polyurethane, and this sort of business, was developed. The reason we can make solid propellant missiles to be launched from a submarine today is based on our work and research.

Mr. NATCHER. Admiral, this group also recommended that a department of science and technology be created with full Cabinet rank, although a department of technology and science might be preferable.

Do you agree with that?

Admiral HAYWARD. Yes; 100 percent.

Mr. NATCHER. What about this further suggestion? The group also suggested that the United States open its laboratories to scientists from all over the world, thus converting the emphasis from space war to a conquest of space, and further that the United States should unclassify a great portion of its present material.

How do you feel about that, Admiral?

Admiral HAYWARD. I agree with that.

One thing that we lack in our country is the ability to take advantage of what a lot of the other people do. Even in our own sciences, this "need to know" business is wrong. Basic communication between scientists is necessary if you are going to get ahead. Let me say the opposition understands this. The Russians spend, I would say, roughly the equivalent to almost a billion dollars in our money a year translating every technical document that comes out of the free world—every one. Even Aviation Week, which I would not classify as a technical document. It is available to the intelligence agencies of the Soviet. And it is available to them to start and know what the state of the art is in our country. They do not go down the wrong streets.

In Russia, a man in my position would be able to press a button and say "Give me a translation of the American Physical Society Journal of October 1957," and it would come up.

If I tried to get a translation of this today, I would hate to tell you how long it would be.

Mr. NATCHER. I want to thank you for your defense as far as the Navy is concerned.

I served in World War II in that branch of the service that won the war. And I am partial as far as the Navy is concerned.

Thank you, Mr. Chairman.

The CHAIRMAN. That does not come within the jurisdiction of this committee.

As an Army man, I admire the Navy. As one who served in the Army, rather, I admire the Navy.

Mr. McDonough?

Mr. McDONOUGH. You have gven us some interesting things to think about here.

I don't disagree with you on your desire to promote scientific research and development to the ultimate. But I am wondering about the progress that, in your opinion, Russa has made over a long period of years going back to 1920.

If they have. I wonder why they weren't better prepared when the Germans advanced against them? They had certainly enough resources. And if they knew how to do these things why didn't they prepare to meet a situation of that kind?

Admiral HAYWARD. This is a good question.

As a matter of fact when you go back to 1928, if you look at their 5-year plans, they were always behind in what they were trying to do. Just remember since 1920 what they were attempting to do. It is a terrific accomplishment. These people have done a terrific accomplishment. Just terrific. Now they weren't ready for the Germans, no.

That is true.

Of course some of the equipment they had, some of the things they did weren't very good.

Mr. McDONOUGH. Well, in World War I, I worked with Russian chemists here in the United States on the development of the detonator—the warhead for torpedoes—for the Russian Government, as a matter of fact, right up in the State of Pennsylvania. We produced tetranitro phenol, which up to that time had never been produced in any large quantities.

TNT was supposed to have the highest ballistics test then.

TNA—you know what that is, and where it is used. The Russian Government was buying it from the United States. They weren't even able to produce it over there. They sent their own chemists here to check to see that the specifications were met insofar as the—well, to be sure that it was acid free, that it was transportable, that it met the ballistics tests that they wanted. And that, of course, gave me an impression as a young man that Russia was not up to it.

When we had to do this for them, I felt that Russia was not up to it.

Then, following World War I, or I think it was World War I—well, shortly after Lenin—and when the first two or three 5-year plans came along, they called for our engineers by the hundreds to come over there to set machinery. Our American engineers informed us that they couldn't with all the apparatus they had, intelligently inform these Russians how to place a piece of machinery on a level base so that it wouldn't rock itself to pieces when they put power on it.

They spent many, many millions of dollars building factories with American engineers. I don't know how recently, American engineers were called over there to do a lot of things; in extracting petroleum, mining of coal, in mine production, in factories, and so forth. I have been under the impression that the Russian people do apply themselves

pretty thoroughly to a project. But they apply themselves so thoroughly to some one project that they forget a lot of others.

I think that we, on a broader and more diversified scale, are better prepared to meet the demands of material production in the event of war than Russia is even today.

Now, from what you say you don't agree with me.

Admiral HAYWARD. Right today on the production side you might be correct. But you are just emphasizing the point I made. How far they have come in those 38 years. It has been tremendous.

Mr. McDONOUGH. That is right.

Admiral HAYWARD. Well, they are graduating 60,000 engineers now a year.

With the same, roughly the same, number of teachers that they have, and roughly the same effort, we only get 25,000.

Now, our strength has always been that we have got to be able to do more with less. Just looking at the curve, the rate of progress of these people, in 10 years we will be so far behind that is is going to be pitiful.

Mr. McDONOUGH. Well, I think we should be concerned about that. But I think we can do and have done more with less than they have. They have the 60,000 engineering graduates. And they are not all voluntary students like you were.

Admiral HAYWARD. That is right.

Mr. McDONOUGH. They are students designated by the Government to train in that particular line for the state. Their whole objective is materialistic. Maybe, as Mr. Sisk said, we are a little too sentimental in our beliefs. We have got a little justice and loyalty and morality and a little more freedom and want more freedom. And we have, true, the freedom of speech and of the press in this country, and we can't do things behind closed doors like they can over there.

Certainly few people in the world knew anything about the sputnik that was coming up. But if we were to attempt to try to put a sputnik in the air or a satelite, it is known months and months ahead.

So, are we leading in the direction of this race for science—and I don't disagree—I have been in science myself, in my earlier years, and I think we need more of it. In this race for science are we losing our way of life? Are we inclined to go off in that direction, to become materialistic?

Admiral HAYWARD. No, sir. I am convinced, you see, in my own mind, that the Soviet, as Admiral Rickover pointed out, have one idea in mind. That is to conquer the world. But not the way most of our people think. Not with hydrogen bombs. I don't think it is going to come to that. They realize and see, I am sure, that it is a fight for man's mind.

This is the struggle. And just look, you may have the hydrogen bombs up to the Capitol over here, but you still may lose all of the world except right here. And if you have done that, you have lost the world.

Look at the past 13 years. Look back, and you can see how naive we were that we saved Western Europe because we were the sole possessor of the atom bomb. This is what we thought. But while we were saying this and while we sat back and thought of it, we lost a whole continent. All we had to do was to read Mr. Lenin, and he told you that the closest way to Paris was through Peking. And we

didn't believe him. We sat with our atom bombs and said, "Oh boy!"

Mr. McDONOUGH. He did it with men's minds.

Admiral HAYWARD. He did it with men's minds. He is doing it with men's minds in the Middle East. When the sputnik went over, what happened? We lost psychologically. You could have hydrogen bombs coming out of your ears and it wouldn't have done you any good. So he realizes this. This is the point I am trying to make, that the United States has to realize that it is a battle for men's minds. And when it is a battle for men's minds they have to be educated. And, of course, one of the hopes I have is that they educate every Russian, because in education, maybe, they will come to see that maybe this isn't right.

Mr. McDONOUGH. We are straying a little from the jurisdiction of this committee, Mr. Chairman.

But these are interesting things.

I agree. I think that the education may create a Frankenstein for this type of Government that they now have, and the more they get, the better I would like it.

However, they have anticipated that.

Admiral HAYWARD. Yes, sir.

Mr. McDONOUGH. They have anticipated that to the point that they want to control the scientific mind, however old it gets, up to a mature age.

Now, insofar as the bill before the committee on the establishment of this Agency is concerned, I gathered from what you say—and I don't disagree too much with it—that you think it ought to be pretty much a straight line of command with not too much diversification.

Admiral HAYWARD. That is correct, sir.

Mr. McDONOUGH. And I think that we should have more than 1 person from the Department of Defense on that group, because 1 man isn't sufficient.

Insofar as the organization is concerned, of course, our space program isn't going to start with merely the establishment of this Agency. We have already started it. We are pretty far advanced. And in the work that we have done up to now, without any legislation from Congress, except for appropriations to go on with certain research and development programs, has there been, in your opinion, much duplication in the various services?

Admiral HAYWARD. Well, that is a good question also.

Of course as a physicist, duplication is not evil, per se.

I call it parallel lines of investigation.

Mr. McDONOUGH. All right.

Admiral HAYWARD. I really haven't seen very much. For instance, the Vanguard program and the Explorer program and the experiments that we have set up, I think there has been some duplication. Of course, one of the problems that faces us is for example, the dispute that has gone on between the Thor and the Jupiter. When the decision to produce something comes up, that is when you have to make those hard decisions. And that is why I want this technical man at the high level to say, "Yes, it will be this or it will be that." Because in the research and development side of the house, this is when you are spending little money compared to, for instance, $1.4 billion in the

Thor. How much have you got in Jupiter? You have $1.5 billion in Atlas.

But the question of where duplication comes in, is primarily important when you produce them.

Mr. McDONOUGH. Are we out of the experimental stage in those two projects?

Admiral HAYWARD. Having reviewed them, we still don't have a weapon.

Mr. McDONOUGH. We are pretty much on the right side.

Admiral HAYWARD. Yes. We are going to meet them.

Mr. McDONOUGH. If anything I ask is classified, you don't answer.

Admiral HAYWARD. All right.

Mr. McDONOUGH. Are we approaching the practical side of the development of a manned space ship?

Admiral HAYWARD. I would say the X-15 program and the X-15-B program make sense.

Mr. McDONOUGH. The X-15 is North American. Is the other Lockheed?

Admiral HAYWARD. 117 (L) program is the Lockheed one.

Mr. McDONOUGH. That is a spaceship?

Admiral HAYWARD. Yes, sir.

Mr. McDONOUGH. That is more advanced than the X-15?

Admiral HAYWARD. Well, this could be open to argument.

The X-15-B has got to come back on land. And as an aviator, this is more difficult.

Mr. McDONOUGH. I think that is all, Mr. Chairman.

The CHAIRMAN. Mr. Keating?

Mr. KEATING. Admiral, you said one thing that rather startled me and I just wanted to ask you about it, because I think these physiological elements that enter into taking a man up and bringing him back, of course, are tremendously important.

I served in India where our service was attempting to assist Congressman Natcher's service in winning this last war. And one day it got to 120° there. We all felt it considerably.

You used the figure 150° as the limit of human tolerance.

For how long a period is that?

Admiral HAYWARD. Well, actually we have had men in such conditions for 35 minutes. And of course some of the fire rooms in some of our ships have run as high as 140°.

Mr. KEATING. For a matter of hours?

Admiral HAYWARD. No. I would say an hour at the most.

The 150° that I gave you is the reentry problem. And that wouldn't last more than maybe 11 to 30 minutes at the most.

Mr. KEATING. I see.

In other words, this 150° was during the reentry period?

Admiral HAYWARD. Yes, sir.

Mr. KEATING. The hottest period?

Admiral HAYWARD. Yes, sir.

Mr. KEATING. For a matter of 10 to 25 minutes?

Admiral HAYWARD. Yes, sir. And we have run programs, and so have the other people, on just what you can tolerate in this line.

Mr. KEATING. Now just one question about this bill.

You have rather leaned to the idea of favoring a Department of Science.

Admiral HAYWARD. Yes, sir.

Mr. KEATING. I don't disagree. I am rather inclined that way. But is this an alternative. Should the director of this agency be empowered to participate in policymaking decisions at the very highest level—which I think he should—should he sit in Cabinet meetings; and with the National Security Council? Do you think he should be given that high a position?

Admiral HAYWARD. Well, if he is given that high a position, then you have to tie the other agencies to him some way. The AEC, the National Science Foundation. He should have the whole ball of wax. And he is going to be——

Mr. KEATING. Well, not necessarily. Am I wrong that the Chairman of the AEC now sits with the Cabinet?

Admiral HAYWARD. Yes, sir, that is right.

For instance there are things that are done in technology that apply across the board. You take the amplification of this molecular atomic stimulation and radiation business, this can apply to space missiles or submarines. So he would be mixed up in the whole thing.

Mr. KEATING. In other words, a Secretary of Science would have a much broader jurisdiction than simply the matters which would come under the purview of this agency.

Admiral HAYWARD. Yes, sir. Suppose, maybe 5 years from now, we have a way of going to the center of the earth. And then you will want to set up an underground agency. So this can go on and on. I think it is time we tied them together into the Secretary of Science, and I would bring them all together.

Mr. KEATING. Well, now, suppose we weren't ready yet—the country, or the Congress, or the administration—to create the office of Secretary of Science, as regards this particular field of activity? Do you feel this is important enough, that the Director of this agency should participate in policymaking decisions at the highest level?

Admiral HAYWARD. Absolutely; yes, sir. It is most urgent that he do.

Mr. KEATING. Let me ask you this: If you think that—and you do—should we provide something with regard to that in this legislation or should we leave it to executive decision?

Admiral HAYWARD. I would provide for it in the legislation.

Mr. KEATING. I would too.

Thank you very much.

The CHAIRMAN. Mr. Ford?

Mr. FORD. Admiral, I wholeheartedly concur in your comments in response to Mr. Natcher's reading of the report of the Senate committee recommendations.

I know rather intimately that the Department of Defense—Army, Navy, and Air Force—over the last few years has recommended substantially greater research and development funding programs than either the administration or the Congress have approved.

Included in those recommendations and in the discussions, the military services have sought repeatedly to increase basic research to a greater degree, in total dollars and in percentage, to that which was made available.

I don't believe that the scientists per se, or certain groups of them, can put a halo over their heads and condemn the military for their views as far as science is concerned.

I agree with your application entirely.

You mentioned that the Navy and research and development have people in about 1,200 private educational institutions. I believe the Army and Air Force is comparable, if you add them all together.

Admiral HAYWARD. Yes, sir.

Mr. FORD. I would like to explore just for a minute your comment where you indicated the technical evaluation by the Department of Defense in July of 1955 made the decision that Project Orbiter should be replaced by Project Vanguard.

Admiral HAYWARD. That is correct.

Mr. FORD. Now, as I recollect the history of that—I may not be entirely correct—wasn't there an 11-man committee.

Admiral HAYWARD. The Stuart committee, yes.

Mr. FORD. Which made that decision?

Admiral HAYWARD. Yes, sir.

Mr. FORD. As I recall, the vote on that committee was by a decision of 9 to 2.

Admiral HAYWARD. That is correct.

Mr. FORD. I don't recollect the membership of that group, but it is my recollection that there were more scientists on there than there were military people.

Admiral HAYWARD. There were no military people.

Mr. FORD. In other words that committee of 11 was composed of 11 eminent scientists.

Admiral HAYWARD. Yes, sir.

Mr. FORD. That was a very important decision.

Admiral HAYWARD. Yes, sir, it was.

Mr. FORD. It was a decision which, rightly or wrongly, had us as a nation not becoming first in getting a satellite into orbit.

Admiral HAYWARD. Yes, sir. But you must, in defense of the scientists, acknowledge that the National Security Council had ruled that we could not interfere with the missile program, so this had a great influence on those technical people as to what they could use. You must remember that Project Orbiter was essentially a Jupiter missile and so they were influenced by the NSC decision.

Mr. FORD. I admit that is an element in their defense. But I refer to the fact that you can't always put a halo over the heads of scientists either, because at least 9 out of 11 of them in this case made the wrong decision.

Admiral HAYWARD. That is correct.

Mr. FORD. As far as the psychological advantage for this country is concerned.

Admiral HAYWARD. That is correct.

However, in looking at the record—and I have had a look at the record of all of that—there were many eminent scientists that attempted to really argue with the NSC decision.

They were told that there was no sense in arguing with it; this was the decision.

As late as 1956, a group of them met and wanted to argue once again with the decision. However, there were some basic technical things that favored the Vanguard decision also.

Admiral Rickover was talking about payload and orbit this morning. This is not necessarily the whole answer. When you tell me about payload and orbit, do you mean that you left the last stage with it?

The Vanguard puts 20½ pounds of scientific payload into orbit. If you left the last stage with it, it would be up to 70 pounds. The reason you separate it is purely for the scientific reason. You want a sphere. You want to get the maximum you can out of this thing, from the experiment that you are designing.

Project Orbiter could not put in the instrumentation the scientific experiments that this committee thought should be done. And also with the IGY commitment, as you remember, at that time it was a purely unclassified approach to the problem.

I am not arguing—I agree a hundred percent you can't put a halo around scientists and say they can answer all the questions. Lord deliver us if they do; because there have been a lot of mistakes they have made too.

Mr. FORD. I thoroughly agree that nothing is more objectionable than Monday morning quarterbacking.

Admiral HAYWARD. That is true.

Mr. FORD. In most cases the people who seek to become Monday morning quarterbacks were in the stands and never played in the ball game. So I have little sympathy for those who sit up there and make comments subsequent to the ball game.

But at the same time I don't think that we should now—bearing in mind that they—the scientists—may have made some mistakes themselves—all of a sudden cloak them with this omnipotence. Because they are as infallible as laymen, regardless of occupation.

Admiral HAYWARD. I make a statement always this way: it is not always the best thing to take the best technical policy, Mr. Ford. But the people who make the decision should know what the best technical policy is; what the technical answer is.

Now, there are a lot of times when the best technical answer is not the best policy, such as here, you see. But what I want to know is, Did the people who made the decision really know what was the best technical one when they made the decision?

You see, I have a feeling myself that they didn't know that Orbiter would work when they made that decision.

Mr. FORD. Well, as I recall, the people who voted against the change from Orbiter to Vanguard were very well informed as to Orbiter's potential.

Admiral HAYWARD. That is correct. Dr. Furnas was one of them.

Mr. FORD. Yes, as I recall, Dr. Furnas, Assistant Secretary of Defense, was 1 of the 2 who so voted.

I don't recall the other one. But it is my recollection that he was someone connected with the Army research and development program.

Admiral HAYWARD. Yes, sir. He was out of JPL.

Mr. FORD. At least one of those people was highly informed as to the good potential of the Orbiter program.

And Dr. Furnas, even though he wasn't connected with the program directly, was in a position where he certainly had full access to all of the arguments, pro and con.

I don't like to prolong that; but I think we must guard against fluctuating as to who is omnipotent.

Admiral HAYWARD. Yes, sir.

Mr. FORD. And I don't place omnipotence in the science ad infinitum, any more than I place it in the military or in civilians.

Because I know that in this particular case there are many who certainly would have agreed that if there was any chance of delaying or impeding our missile program per se, that they would have sided with the decision 9 to 2.

Admiral HAYWARD. That is correct.

Mr. FORD. That we should not have taken Orbiter out.

Well, I gather from your comments that what you presented to us here is your own view as to the legislation, but you seem to indicate that perhaps the Navy's views will be submitted, officially, later.

Admiral HAYWARD. Yes, sir. That is my view. And it is the Navy's view. We are for this legislation with these changes that I recommend. And we will present this officially to you.

Actually I must say we are delighted—this is the way it should be done. It shall have a strong committee in Congress to back it.

Mr. FORD. I am concerned with the provision which says that there shall only be one—that is a minimum, from the Department of Defense.

The CHAIRMAN. Not less than one.

Mr. FORD. Yes, it says "not less than 1 out of the group of 17."

Admiral HAYWARD. Let's put it this way. It should be responsible to the military. You have two paths that you can go down. You can do it this way by putting maybe more than one from the Department of Defense or you can go down and have a military liaison committee like you did with the AEC. And actually I can see nothing wrong with this.

I mean, that legislation has worked very well. And that might be better because they work day to day, the Atomic Energy Commission.

Mr. FORD. Is that a permanent group?

Admiral HAYWARD. That is a permanent group; the Assistant Secretary of Defense in the atomic matters. They work day after day on all of the programs with the Atomic Energy Commission. They live with it. Where this committee is only going to meet four times a year, they are out in the field. In order to be responsive to the military I think you should go down to the Military Liaison Committee standard yourself.

As a matter of fact, under this legislation, is there any reason why you couldn't make the same Military Liaison Committee to the AEC the liaison committee to this Agency? I don't know.

Mr. FORD. From a practical working application of the AEC setup with the military liaison committee, do you have this problem of interservice rivalry, competition, and so forth?

Admiral HAYWARD. No, sir. On this committee—and I will say, which was established of course by the statute—the present Assistant Secretary of Defense is a retired Army general actually that runs this. We have representation. We have our own research and development programs that we feed into this group.

As a matter of fact, the atomic weapon business is one of the best run and the best coordinated businesses in this whole situation. This is one of the agencies that was brought up and started—you don't have anybody making their own atom weapons at all. You don't have this problem. They are very responsive to the military.

Mr. FORD. Taking this proposal here, you infer that maybe 17 members were too many.

Admiral HAYWARD. Yes, sir.

Mr. FORD. And you tend to indicate that one from the Department of Defense is too few? Don't we get ourselves in the position of trying to restrict the size and increase the membership of the military?

Admiral HAYWARD. No, sir. What I mean is: If this agency is going to be responsive to the military, and you depend upon this one representative from the Department of Defense who sits on a committee of 17, four times a year to find out what is going on and what they are doing, they are not going to be responsive. So that is 1 reason why 17 is too many. What are they going to do four times a year? Kibitz the Director, tell him this or that? Are they just going to cover matters of broad policy? Will they present the budget? Just where do they fit in and what do they actually do?

To be responsive to the military—and I think the intent, you see, is to have the NACA—that is very responsive to us. We have no problems with the NACA. But we live with these people, remember. Their laboratory is at Langley Field. Their high-speed laboratory is on Moffett Field. We live with them all the time. I am sure the intent of your legislation is to have this same thing occur with this agency.

The CHAIRMAN. It is vitally important.

Admiral HAYWARD. Yes, it is vitally important.

The CHAIRMAN. It isn't simply a question of commonsense in the world of today that there be that close relationship, it seems to me.

Mr. FORD. Does NACA have an advisory board?

Admiral HAYWARD. Oh, yes, sir. They have 17 people.

Mr. FORD. How many of the military are on the Board at the present time?

Admiral HAYWARD. Right now NACA has 17 people. Two from the Air Force. Two from Navy, two from Civil Aeronautics Authority. One from Smithsonian. One from the Weather Bureau. One from the Bureau of Standards.

Then you have the remainder of them, 7 civilians, and you have 1 from the Research and Development; and of course the Chairman is elected by the Committee.

Mr. FORD. Of course this new Agency may have a different relationship with the military, as I envisage it. NACA today does jobs for the military. Under this new proposal, the military will be, in many cases, doing jobs for NASA.

Admiral HAYWARD. That is right. When you say the NACA does jobs for us, they do all of the basic aerodynamic work. You take the area rule that we put on our fighters and everything else, the NACA is not in the production business. The NACA is a scientific job, and their work is available to my friends, the Russians, who translate all of their documents; they are also available to our commercial airliners, to anybody in the world who wants to go down there and pay 50 cents for discussion on the area rule or anything of that kind.

Now, this committee and the NACA—I happen to have sat on one of their panels. I was the Navy's representative from supersonic aerodynamics. We work very closely with them. In this legislation, I don't see anything in there—I am sure the intent, as the Chairman said, was to have this relationship continue.

But it certainly isn't in the legislation as it exists today. It should be if you are going to tie these two together.

Mr. FORD. From a personal point of view, if you had your choice between legislation which would set it up on the basis of the AEC program or the proposal here, which would you prefer?

Admiral HAYWARD. Well, having lived under Government by Commission, sometimes it can get pretty hard. I do like the directive that you do have a Director, and I would like to have a committee of maybe 5 or 7 people. Then I would tie the military into it with this MLC approach more than anything else.

Now, this agency in order to launch some of their things obviously are going to have to go to Patrick, or the Pacific missile range. So we are going to have to be tied in from a logistic point of view.

But I think here you have 17 men meeting 4 times a year. If this is the only responsiveness, is this DOD Committee on this 17-man committee, it isn't good enough.

It should be spelled out in the legislation.

Mr. FORD. Thank you very much.

The CHAIRMAN. Admiral, back in 1954 when the Riehlman committee made its inquiry, we were trying to inquire constructively as to some of the bottlenecks and the difficulties experienced in research and development. We found that a considerable part was due to personalities in connection with the background and training of honorable and dedicated men. And we made a number of recommendations at that time which we thought were improvements in the situation. One of the recommendations that I remember we made, was the advisability of the services offering encouragement to officers like yourself, and young officers, in particular, to make a career in the service of our country dedicated to science, and technology, and its various aspects, without imposing these constant changes in tour of duty, and even to the extent of creating a separate corps, if necessary, like the Army Engineers, where officers would have the opportunity to advance.

Has anything been done on that? Has anything been done along that line?

Admiral HAYWARD. Well, of course, we are short of them. We lose them, Mr. Chairman, all the time. I mean good ones. We can't keep them. There are just so many, really.

I am sure you are familiar with our program of education along this line where all of our officers practically go to graduate school now. But it is pretty hard. You take a class as long ago as 1937 that went to graduate school—and we didn't put enough in graduate school then, I will admit—of 20 people; today you will roughly have maybe 3 left. That is the attrition.

Those people—well, in my own case it is awfully tempting some time when you want to pay your bills and everything to take a big job outside. And we are faced with this. We have stabilized the tours of duties of our laboratory commanders which the Riehlman committee recommended. We have definitely made the civilian scientist our partner.

Your committee actually investigated my laboratory and asked the Army why they couldn't run it that way too.

Dr. Bennett was the Director of it and had the responsibilities. I couldn't agree more about the tour of duty business.

However, I would hate to separate it completely from the operational side, because actually I feet that having to go to the wars and seeing the problems faced by the people, a lot of times, is a great advantage.

Now, the OSRD during World War II actually sent their people out into the field to see just some of the conditions that were faced. So, if you separate them completely, I would be more bothered. But I have to agree with you that we could do a lot better in keeping the tours of duty at, let me say, a much greater length of time.

I realize I might be sentencing myself to stay in Washington from now on, Mr. Chairman. And of course the tenure of life of the heads of research and developments of services has gotten to be very short.

My son said, "General Gavin has quit, General Putt has quit. When are you going to leave, Dad?"

I agree with Rickover on that. We could do a lot better.

The CHAIRMAN. Our investigation was not for sensation. You remember that.

Admiral HAYWARD. I realize that.

The CHAIRMAN. We weren't looking for some things to nibble at every human mistake. We weren't looking with hindsight. At that time there were a lot of difficulties that were more or less connected with the human equation. That is my impression at the time.

You say there has been a decided improvement.

Admiral HAYWARD. Well, there has been some improvement. We still have plenty of trouble, I can assure you of this, in not keeping permanency of personnel.

This is just something as you say, everybody wants to get ahead.

The CHAIRMAN. That is a human trait.

But are they affording more people the avenues of opportunity of going head, and of recognition?

Admiral HAYWARD. Yes, sir; we have. Take my case as an example. I was selected for admiral way ahead of my contemporaries.

The CHAIRMAN. Public opinion plays an important part when once aroused.

Admiral HAYWARD. Yes, sir. This is true.

Back in 1956, I was probably one of the few Democrats in Washington. They wouldn't give a Republican command of the *Franklin D. Roosevelt*, so they made me captain of that for several months, Mr. Chairman.

The CHAIRMAN. You talk about the Polaris. Can you discuss some aspects of it?

Admiral HAYWARD. Yes, sir.

It is our belief, of course, in solid propellants because we can't readily put liquid propellants in a submarine. And the Navy, during World War II, went down the line with the solid propellants. It has quick reaction time, can be maintained easier, and is just a better type of propellant for the IRBM than the liquid.

Liquid oxygen and JP–4 have plenty of problems, as well as some of the other exotic fuels that we have. Well, take this Polaris, which has a solid propellant; I feel it is the best missile in the country for this particular job.

The Polaris program is possible only because of the basic research we did on solid propellants. There are lots of problems in manufacturing large grains and casting these things. The metal parts, the warhead, and so on.

Four years ago we did not think it possible to do this. Today we do. And we have what I think is one of the outstanding missile programs in the country with the Polaris.

It worries me, however, because if we can do it, Mr. Khrushchev can do it also. And so we have to protect ourselves against this. And it worries me that everybody looks to the North Pole, when right 50 miles off our coast, why, every Russian submarine could be a potential missile-launching submarine. We have to have some defense against this.

So, it has brought some very hard decisions on the Navy, the decision not to build the new carrier, the decision to really try and do something in the antisubmarine business has been a hard one. We have been handicapped. Maybe we haven't been smart in the way we have tried to sell it to the public. We do not try to scare the people. From my point of view, this threat to the country is one of the greatest ones we have ever faced.

It has a lot of problems such as political ones. Suppose we do see these submarines out here. Suppose I track them all. What do I do about it? Do I sink them, or do I just tell everybody that there are 50 of them out there? Is there a magic number when I say "Well, look, we have a hundred out here now. What are you going to do about it?"

Maybe the day will come when we will be forced, as a country, to say that any submerged submarine within a certain radius of our homeland is a hostile act and we are going to sink them. I mean this might come.

But we have to first lick the problem technically of being able to locate, classify, and destroy these submarines if necessary. And it is a terrific problem. This is why Polaris—every day that I see Polaris in its success as it goes on, that worries me more.

The CHAIRMAN. Has the test been completed?

Admiral HAYWARD. We had a shot today. I hope it went well, I did not hear the results. We have been making flight tests and I think it would be very worthwhile if Admiral Raborn came up and had a closed session to brief you completely on it.

The CHAIRMAN. It is the firm judgment of Admiral Raborn and you and other men, other gentlemen, officers, that going ahead with the development of submarine types is advisable?

Admiral HAYWARD. Yes, sir.

Mr. FORD. Mr. Chairman, would you yield?

The CHAIRMAN. I would be glad to.

Mr. FORD. May I suggest rather than have Admiral Raborn come up here, it would be much better for us to go down there?

Admiral HAYWARD. That is right.

Mr. FORD. You would really see a first-class demonstration.

The CHAIRMAN. We will keep that in mind.

Can you give in open session any evidence as to the distance of the Polaris?

Admiral HAYWARD. Well, the requirement, yes, sir.

It is a 1,500 nautical mile intermediate range ballistics missile to be launched from a submerged submarine.

The CHAIRMAN. Probably can be extended too?

Admiral HAYWARD. Yes, sir.

The CHAIRMAN. We read a lot about satellites and that the satellites sent up, of course, were probably more or less experimental. But, friends of mine who are well versed and in whom I have confidence tell me that, while present satellites have no military significance, they could have a great future military significance; that satellites could be used and utilized for almost any purpose other than putting a human in them, if they wanted to achieve a specific purpose.

Would you care to comment on that?

Admiral HAYWARD. There are some things about satellites that people right at the moment, let us say—well, nobody has repealed Newton's law. And if you get up there on a satellite and try and drop something on the United States, if you throw it out, it is just part of the satellite.

In order to use a satellite to get something back to the earth, you have to propel it so that it has a zero angular momentum with the earth. And it is a pretty hard job to hit it. I mean hit where you want to.

However, I agree that even though at the moment all I can see from a military application is reconnaissance, communications, navigation, and intelligence purposes generally; you must remember when the airplane first flew they said this also about the airplane, that it was only going to be good for reconnaissance. So, we have to have imagination on it.

I am sure it will have military applications, but I cannot tell you in specific detail other than those I just named.

The CHAIRMAN. Is the mere weight of a satellite of importance in establishing a lead over a competitor?

Admiral HAYWARD. It is important in one basic assumption, which is the rocket thrust.

In other words, the amount of weight that one can get into orbit is a function of what we call the mass ratio. And that is E to a ratio of the velocity you need over the velocity of the exhaust gases. I won't get into technical details on it. But from this mass ratio one can calculate pretty much the thrust of the engines required to put something, a given load, into orbit. And on the basis of this, mere weight and weight along could indicate that the Russians have very fine rocket engines.

Now, of course, there are some factors—how many stages you have, and does he have the fourth stage hooked onto it—that would change it. But it is my belief that the Russians are ahead of us in rockets, particularly large thrust engines.

There is no question about it. I don't think any technical man would question that they are ahead of us. And I base this from more than just the weight of the satellite that they had, just from the rest of the intelligence we have also.

The CHAIRMAN. It is quite important that at no time are the Soviets in the position where they could hit us and we could not reach their targets; isn't that true?

Admiral HAYWARD. That is correct. This is very important.

This is why we feel in the Navy that in this war business—war is very complex now, Mr. Chairman; war covers a spectrum. It covers a spectrum all the way from the megawar or the all-out atomic exchange, down to what is going on in Indonesia and all the rest of them.

Now, this deterrent force we have, we have to have more than one

way of destroying the Soviet. If ever the Russian planner—and it is what the Russian planner thinks, not what we think—if he ever thinks he can destroy us without our destroying him, I am convinced he is going to do it.

Now, that means that this deterrent that we have cannot be the Strategic Air Command; it cannot be just Polaris; it cannot be just Atlas. You have to have a flexible posture so that you present to this man a practically impossible situation that no matter what he does in that megawar situation, he is going to be incinerated.

Now, this is the point—this is why we say Polaris is important. We don't expect to do away with the Strategic Air Command. You are going to have manned airplanes for years, the same way with the Atlas. But you are going to have a mixture and a flexible posture. And if you don't, then you always leave yourself open to having the Russians defeat you by being able to destroy a single force.

Now, I am convinced in the Vanguard situation that they knew everything we were doing. It was unclassified. They saw what we were doing. And they said, "Boys, here is a good chance." And they understood the psychological side of it. And they went down their alley.

And they will always go down the road that you neglect, do the things that you don't do; if they see a psychological advantage in it. And this is what they did there.

And if they could defeat our Strategic Air Command today—and if the Russian planner thought that, he would do it. But he can't. He has too many problems facing him.

He is ringed in by everybody. And he looks to the day when maybe he can.

So, we must have that flexible deterrent. If you just go down the all-out war business route, you are going to wake up some day to the fact that Africa, Asia, South America, and everything else is Communist, and you will be alone.

Then all you will is the choice of pulling the world down around your head, which you will never do.

The CHAIRMAN. If that ever happens, they could cause a lot of division among our people. You know, the primitive appeal—race, color, racial origin.

Admiral HAYWARD. Yes, sir.

The CHAIRMAN. But we won't go into that. I have thought of it many times. You talk about this liaison committee, on which I followed your testimony very closely.

It is hard to write into any bill language covering every possible detail, because no one knows what human action is necessary in administering a law or establishing an agency, an agency established as a result of a law. And in the world of today, at least in my mind, the military aspect has got to be given great emphasis. That doesn't mean control, however.

But the recognition of what, to me, seems to be inescapable is that in case of war we must look to you gentlemen to lead us, you gentlemen who wear the uniform. And I never forget it. The thought in my mind is that in the case of war these are the gentlemen we have got to look to, the leaders, to win the war.

The liaison committee, as I see it, without making a definite decision, would be able to bridge a lot of gaps between the civilian con-

trol—and would permit a lot of meetings where there could be quick agreements and might make more effective the operation of any agency we establish in connection with the importance of the military.

Admiral HAYWARD. I agree 100 percent with that, Mr. Chairman. I really think it is necessary and in the transition phase, this would work.

The CHAIRMAN. I will be frank. I hadn't thought of the significance of it until I listened to your testimony. It impressed me very, very much.

Are there any further questions?

Mr. Feldman.

Mr. FELDMAN. I only have one other question to ask, Admiral.

Did I understand you to say that you also believed in having such an agency responsible to a strong congressional committee or a joint congressional committee?

Admiral HAYWARD. Yes, sir.

Very definitely it has to have a strong congressional committee, and somebody that really follows the program and has a good staff. This is the Joint Committee on Atomic Energy. They have always lived in our pocket on this. This was a good idea and should be done in this business.

Mr. FELDMAN. Do you have any opinion as to whether or not the bill should have a provision making the Director a member of the Security Council or some such level?

Admiral HAYWARD. I answered Mr. Keating and I would repeat what I feel. If you don't have a Secretary of Science—and you say you put this legislation through now—I would recommend that in there you put him at a real high level, yes sir.

And then anything else that you ever did with tying all these technical agencies outside the Department of Defense together, then you would bring him into that. But at the moment, I would put him at a real high level, yes sir.

Mr. FELDMAN. Thank you.

The CHAIRMAN. There is just one feature of the bill that I would like to read. It is not a part of great importance. We pass on it. But I would like to get your views on this:

> Subject to the civil-service laws, to select, appoint, employ, and, subject to such regulations as the President may prescribe and without regard to the Classification Act of 1949, as amended (5 U S. C. 1072 et seq), and the Federal Employees Pay Act of 1945, as amended (5 U. S C 901 et seq.), fix and adjust, as nearly as consistent with the public interest and on the basis of equal pay for equal work at rates which are reasonably comparable with prevailing rates paid by non-Federal employers for similar work, compensation of such officers and employees as may be necessary to carry out the provisions of this Act.

I have no objection to that. But, on the other hand, I am wondering, from a relative point of view, how it might affect you, for example. Suppose the scientist in this Agency got the higher salary than the scientist in yours. What effect would it have?

Admiral HAYWARD. I have thought about this Mr. Chairman, having had to work under the Classification Act and having worked with the AEC. The contract operation of the Atomic Energy Commission gives you much more flexible use of your people. I feel, as a matter of fact, that it has certain advantages over the civil-service classifica-

tion setup. And if you know the scales as things exist today, at the lower rates in the GS–7, 8, 9, 10, they compared quite favorably with the outside.

It is after you get up to about GS–10 where you can't compete. You begin to lose your valuable people to industry then. This will have the effect of having the people that work in, for instance, the Naval Ordnance Laboratory; all of your good Government scientists who work under the Civil Service Act—these people could take them away from the civil-service side of the house. I am not so sure this is desirable.

The CHAIRMAN. Still, they are civil-service employees. This doesn't relate to the employees who are contractors.

Admiral HAYWARD. No. This is civil service.

The CHAIRMAN. What effect would it have on scientists associated with you?

Admiral HAYWARD. They would probably want to come to work for these people if they offered them more money, I am sure. This is what happens.

The CHAIRMAN. So that, if we keep that provision in there, it should go across the board, then?

Admiral HAYWARD. That is true.

The CHAIRMAN. Or strike that particular provision out, as much as I would dislike seeing that happen. If that stays in, we should go across the board and have it apply to all similar employees—officers, and employees that are in similar positions?

Admiral HAYWARD. That is correct. I have given a lot of thought to this and looked over past history.

The original Classification Act and the original blue-shirt employee, as you know, were not brought up. We have tried at several times as a result of the Riehlman report really to establish a scientific register under civil service, to no avail.

We have gotten some latitude. The Civil Service Commission has gone ahead, for instance; in the laboratories they would let us classify the jobs and say what we should pay for them. They did not send somebody in who was purely a personnel man and say this job should be in GS–12. They let us technical people classify what the job required.

This was quite an assistance to us. But my feeling would be that all of your Government laboratories—we have real good ones outside of the Navy, too, and the NACA—but if you wrote this provision in here, it should be written in the others. It should go across the board for the professional and scientific people in the Government. Otherwise, we are in trouble. We will lose our people. No question about it.

The CHAIRMAN. Mr. Feldman.

Mr. FELDMAN. One further question: Would you recommend, because of your experience with AEC, that corresponding liaison be set up with the AEC as we set up with the military?

Admiral HAYWARD. Yes, sir. In this manner: It is going to have to be, because some of the technical programs that this Agency will be engaged in will go across the AEC's research problems as much as ours. And this is one of the reasons for tying all of those technical agencies outside of the Department of Defense together.

Now, how you do this, or whether you just leave it up to the initiative of the Agency, whether you put it in the legislation, I would say no, I would not put it in the legislation with the AEC, because I feel that they will have to, by technical reasons, get together.

Mr. FELDMAN. We have had testimony from various witnesses to the effect that, in order to have a sustained program and one that is not necessarily immediate but will show results in the future, we would probably have to have the development of a nuclear-propulsion engine.

Admiral HAYWARD. That is correct.

Mr. FELDMAN. For that reason, it might be necessary to keep close liaison with AEC. And, if you spelled it out in the law, it might avoid any difficulties that could arise or that might possibly arise.

Admiral HAYWARD. Yes. Of course, you cannot cover all contingencies in the legislation, because we should have close relationships with the Bureau of Standards, the National Science Foundation, and so on. All of this—and the AEC, of course, is going ahead with nuclear propulsion. We will have it for rockets. This is not a hard problem. Admiral Rickover was not familiar with the program, but I am. It is easier to make a nuclear rocket than to make the hydrogen bomb. This is nothing too difficult.

Mr. FELDMAN. I realize, Admiral, that you cannot go on and spell out everything in the act, but there are some important areas. One is the military. The other is the Atomic Energy Commission.

Admiral HAYWARD. Well, all right; I hadn't thought of it, really, Mr. Feldman, along this line. I agree with you. You should cover it in some manner. I had thought more of the responsiveness to the military and the military liaison approach.

The CHAIRMAN. Apparently, on the Atomic Energy Committee, the drafters of this bill had something in mind, because they said the Atomic Energy Commission may authorize access to restricted data by the atomic-energy prospective contract licensee or prospective licensee of the Atomic Energy Commission, and so forth, and so on. So they recognized there was a relationship there. And whether that should be strengthened or not, I am not going to pass on now. So, apparently the drafters of the bill had something in mind.

Admiral HAYWARD. Yes, sir. You would have to cover that. Otherwise, it would not have any access.

The CHAIRMAN. Projecting my mind into the future, I am in quite general agreement with you. Sooner or later, there is going to be a Department of Science. I introduced a bill in the early part of the session and I made it "Department" because I recognized—well, you cannot force the "Department" upon the President. Congress could pass a law, but a wise Congress would not undertake to create an additional department unless there is responsiveness from the President.

Mr. FORD. May I ask a question there, Mr. Chairman?

The CHAIRMAN. Yes.

Mr. FORD. My views are apparently quite similar to the chairman's and the admiral's in reference to a Department of Science and a Cabinet officer. But didn't some representative group of scientists, national scientists association, or something, take a stand contrary to that in recent weeks?

Admiral HAYWARD. I don't know, Mr. Ford. But maybe they did. This is one thing about scientists; if you ever get agreement

among them you had better be suspicious. Because they very seldom agree. Look at the problem we are faced with today. Take Dr. Killian; I would be very interested to have a man of that stature at that level with his job defined. I mean, what are his responsibilities, you see.

Now he is a very powerful man today. And if he wants to stop something he can stop it. His particular position today—I mean he is ex officio.

The CHAIRMAN. It is determined by the will of the President?

Admiral HAYWARD. Yes, sir; that is correct. But what are his responsibilities?

The CHAIRMAN. I started to say that whoever drafted this bill apparently had in mind that there might be an extension, because section 8 says "For a period of three years after the effective date of this Act the agency with the concurrence of the head of the department"—there is a double negative there, but we can pass that over—"concerned and with the approval of the President"—the negative on the President—"the Commander in Chief, and the Chief Executive"—but that could be taken care of—"may transfer to itself any function" and so forth "of any such department or agency which relate primarily to the functions of the agency as set forth in this bill."

So I think that it is only a matter of time of applying the law of natural consequences when it is bound to develop into a department. And certainly it is going to get far broader than even this bill. Because you might have all these research activities scattered around where they are all related without connecting them together.

Any further questions?

Mr. O'BRIEN. I just wanted to make an observation.

I listened very carefully to the admiral and to the questions by Mr. Ford. I wanted to say, from what I have heard here in the last several days, that there is no indication that the military throttled science during that difficult period. And also all the evidence indicates to me that the military filled the vacuum to a great extent. And if it hadn't, what was a setback in the space field could have been a catastrophe.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. I think I have been asking almost every witness about this statement that has been attributed to Dr. Norris Bradbury. And I am sorry I overlooked directing the question to you. And apparently you were the person I very definitely should not have overlooked on that question.

Now, do I understand you to say that you agree with Dr. Bradbury's statement that it would be easier to make a nuclear propulsion engine, let's say, or reactor, that would move a spaceship, than it was to develop the hydrogen or the atomic bomb?

Admiral HAYWARD. Yes, sir.

Having been involved in both of those, why, I am sure it is easier, and having seen it also.

Mr. SISK. Let me ask you this: Are we progressing as we should? Are we doing the research and development work on that phase of space that is in line with the urgency?

Admiral HAYWARD. Yes, sir.

We have two very good projects, the Atomic Energy has; they have been responsive to our requirements on it.

I can go into the technical details of it. They are very well funded. We will have this, both in the straight rocket and probably in the ramjet.

Mr. Sisk. Thank you.

The Chairman. Thank you very much, Admiral.

For myself and the committee I express our sincere thanks to you.

The committee will go into executive session.

(Whereupon, at 4:50 o'clock, the committee went into executive session.)

ASTRONAUTICS AND SPACE EXPLORATION

MONDAY, APRIL 21, 1958

House of Representatives,
Select Committee on
Astronautics and Space Exploration,
Washington, D. C.

The committee met, at 10 a. m., pursuant to recess, in the caucus room, Old House Office Building, Hon. John W. McCormack (chairman), presiding.

Present: Representatives McCormack, Brooks, O'Brien, Metcalf, Natcher, Sisk, McDonough, Fulton, Keating, and Ford.

Present also: George J. Feldman, director and chief counsel.

The Chairman. The first witness today is Dr. John P. Hagen, Director of the Vanguard project of the Naval Research Laboratory.

We are very glad to have you with us today, Doctor. Have you a prepared statement?

STATEMENT OF DR. JOHN P. HAGEN,[9] DIRECTOR OF THE VANGUARD PROJECT, NAVAL RESEARCH LABORATORY

Dr. Hagen. No, sir; I have some notes I would like to speak from for the moment.

The Chairman. You may proceed.

Dr. Hagen. It is a great opportunity for me to be here to talk with the committee concerning this bill. I think the work of this select committee arises because the Russian satellite accomplishments brought into focus, and into the public eye, the Soviets' determined national effort and singleness of purpose not only to lead the world in the arts of weaponry, including ballistic missiles, but to base this effort on a broad foundation of education, research, and science and technology with the very obvious purpose of outstripping and perhaps dominating the world we know and the world that is to come. It is also obvious that the Russians have a plan for doing this and are dedicated to the task.

Now, this is their challenge to the free world. It is most gratifying to those who have directly shouldered some of the burden in meeting this challenge to have foremost representatives of the American people, such as this committee, apply their talents with vigor to the job of preparing enabling legislation.

---

However, before we figuratively leap into space we must learn well the lessons of the past, carefully examine our present needs and bring our resources forward with purpose and utilize them wisely to their maximum potential.

We should revitalize the free spirit of inquiry which is so essential to our democratic way of life. We should investigate rather than fear the unknown and allow freer range of the long too-dormant pioneering spirit which made our country great. We should also assume a mature attitude toward failures and suggestions which are indeed the price and the reward involved in ventures of great risk.

Any of these ventures in space are going to be ventures of great risk because rockets are essentially risky. The history of Project Vanguard can teach us many lessons and we should learn them well lest history repeat itself in a more unfortunate way than the relatively harmless "beep" of the Soviet satellites.

First, let us establish what Vanguard is. Vanguard is a United States project in the International Geophysical Year; its prime purpose is scientific research. The job assigned was to establish at least one scientifically instrumented satellite during the International Geophysical Year and to prove that it was in an orbit. Now, the International Geophysical Year ends on December 31, 1958, so the guidelines given us were to do the job by that date.

To do the job we established an organization and planned a program including development of a suitable launching vehicle, since no existing vehicle met the specifications necessary to do the job when we started in the fall of 1955. Our early plan had been to build around the vehicles developed by the program to do the job. That is, to establish the satellite we planned a series of 13 to 15 vehicle firings; the first 7 or 9, dependent on progress, were to be used in the vehicle test program to develop the launcher itself; and the last 6 to contain scientific satellites.

The first three vehicle test firings, in May, August, and October 1957 were all extremely successful, but none were tests of the complete three-stage launching rocket. However, they did prove to us the soundness of our paper designs for the final complete vehicle. So in July of that year we decided that the remaining test vehicles would contain small satellites on the chance that one of the test vehicles would perform so well that the small ball would be pushed into orbit.

The first tests of the full three-stage launcher were made in December 1957 and February 1958. As is usually the case, and has in fact been the case in all missile development programs, these first test vehicles did not perform to final design objectives; but that was precisely why we fired them—to find out what else needed to be done.

On March 17, 1958, the untiring efforts of the Vanguard organization paid off. The small test satellite and the third-stage rocket are in a very high and stable orbit around the earth. The satellite will last for a long time, presently estimated at not less than 200 years. Most important, the very advanced design of the Vanguard rocket proved its capability. We have assigned the eight rockets we have left to the full-scale scientific satellite launching program. With these we will attempt to launch very sophisticated earth satellites to complete our obligation to the International Geophysical Year. Now, this is a tough business and the risks are great in terms of successes and failure. Both can still be expected.

As I have related, one might ask why are we so disturbed when Vanguard seems to be doing its assigned job in an orderly fashion. This is precisely the point.

The project represented a major national and international commitment which, in our opinion, was hampered in its early stages by these things:

(1) Too low a priority in the overall scheme, (2) virtually no industrial priority, (3) piecemeal funding which caused a lot of waste motion and cast a pall over the technical area, (4) too many administrative channels and levels to go through in order to get policy decisions and funds in the time limits with which we were dealing.

Now, in spite of these problems we have developed an organization and facilities which at present constitute the only complete package unit having the inbeing capability to conduct a satellite and space program. This includes: (1) The major functions of vehicle development and launching, (2) satellite design and scientific instrumentation, (3) radio tracking and scientific data telemetering, (4) orbit analysis and data reduction.

Earlier I mentioned that our chief international competitor obviously has a plan and is rapidly applying his energies to the fulfillment of that plan. I am sure he is not wasting any talent which can be used to achieve his goal, and that he has complete plans for full utilization of all of his talent for a long time to come.

Now, as an index of the state of our planning, project Vanguard has been given no go ahead of funds for a continuing program past the end of this year. We have forwarded very comprehensive plans to higher authority over the past 6 months, proposing scientific and military application of satellite units and space vehicles as the next logical steps beyond the present IGY Vanguard program.

The CHAIRMAN. What is that statement, Doctor?

Dr. HAGEN. We have forwarded many comprehensive plans to higher authorities over the past 6 months proposing scientific and military application of satellites and space vehicles as the next logical steps beyond the present IGY Vanguard program.

The lead times involved in this type of program are long and critical. Now, we feel strongly that the Vanguard organization is a national asset which should not be allowed to waste a day. It is highly complimentary to have the Air Force and the Army combining the Vanguard second and third stages with their large Thor and Jupiter first stages in spectacular moon probe vehicles, and indicating their need to use other Vanguard-developed hardware such as guidance equipment. However, to keep the country from slipping further behind in scientific and military applications we have asked higher authority for funds to go on to an advanced Vanguard program. The current lack of specific authorization of funds to continue our job, I have brought up to illustrate two points.

First, in considering the implications of the bill we are discussing today. The country needs a master plan for the conquest of space—a plan based on a sound scientific approach; providing adequate facilities, funds, and delegated authority to those entrusted with the job; and allowing them to proceed immediately with the first steps in the program. This master plan is essential before we can intelligently discuss an organization to carry it out.

The second point concerns a basic but related problem, the so-called shortage of scientists and engineers. I feel that this problem is somewhat exaggerated and is due in part to improper utilization of the talent presently available. As a part of this problem, there is the salary inequity which exists between scientists doing roughly the same work at gross differences in salary, with the civil service classified employee always at the bottom of the heap. For instance, the top five men on the Vanguard staff, all of whom bear extremely heavy responsibilities, are classified employees who average about $12,000 per year. Similar responsibilities in industries rate from 30 to 100 percent more in salary. Now, to maintain a balanced program the Government needs good scientists and good scientists should not be penalized earningwise, nor should anyone working in government.

That is the end of the statement I wish to make. From here on I am prepared to comment on specific questions about the proposed legislation and to answer any question as best I can.

The CHAIRMAN. Do you attach great importance to the necessity of an agency being established by law that will effectively administer this particular field?

Dr. HAGEN. Yes, sir; I do.

To return to that point about master planning, we should have a very comprehensive master plan and have it keyed in time so that we do have specific plans for achieving specific purposes by a specific date; and the only effective way to carry this plan out would be to have an organization such as the one proposed in this bill, charged with the responsibility and the authority to do the job.

The CHAIRMAN. Should the agency be on a high-level, decision-making basis?

Dr. HAGEN. It must be, for many reasons. My personal opinion there is that the agency should have a board, or a group of some sort, appointed by the President and responsible to him, for policy matters. The affairs of the group might be handled better and more efficiently if this policy-controlling board or group were not a part-time group but a small full-time board determining policy for the director, and if the program directors under the director executed this policy and were responsible to him for it. The board must be of such a high level that it is responsible directly to the executive.

The CHAIRMAN. Do you realize under the bill proposed that that is not provided for?

Dr. HAGEN. Yes, sir; I do.

The CHAIRMAN. There is a board of 17, which is the old board in theory, but in practice it continues as a part-time board, meeting at least four times a year, but instead of being above the director it is now below the director in this bill. Do you realize that?

Dr. HAGEN. Yes, I realize that.

I did not mean to imply that the board would be above the director. I felt that the director should be a member and perhaps the chairman of the board.

The CHAIRMAN. Do I take it, then, instead of the single director over the agency, you prefer a commission over the agency, say, five?

Dr. HAGEN. With the director being the executive director of the group.

The reason I believe this is the following: We are in for a long history of projects with tremendous public appeal. They are going to have a tremendous urgency about them, so that the plans and the carrying out of the board's policies are bound to be continuously changed; therefore the governing board must be always accessible to the director. It would seriously hamper his operations if he had to wait for periodic, say quarterly, meetings of the board in order to proceed with radical changes in his budget or his policy.

The CHAIRMAN. There are two ways of doing that. One, a director of the board along the lines you have said; the other is the commission and then, of course, the chairman of the commission would be in a comparable position to the chairman of the other commissions. Which method do you prefer between those two?

Dr. HAGEN. Sir, I did not quite understand the question.

The CHAIRMAN. I take it you do not like the idea of the 17-man board.

Dr. HAGEN. Yes.

The CHAIRMAN. Do you believe it should be a full time small board?

Dr. HAGEN. Yes, sir.

The CHAIRMAN. Always available and serving the Government in a full-time capacity?

Dr. HAGEN. Yes.

The CHAIRMAN. There are two ways you can make a full-time commission. Say it is five members, or three—I do not care which; I just wish to have your views—you could have a commission form of an agency, or an agency under the director of the board to advise them. Which would you prefer?

Dr. HAGEN. I would prefer the commission form although I must admit that the formation of a board under the director could possibly work as well. However, the stature of the individuals on a commission might be higher than the stature one could obtain in a board under a director.

The CHAIRMAN. Have you information that the Soviet Union is engaging in great activity in this particular field?

Dr. HAGEN. The information available to us—just the released information, the kind one obtains from newspaper and magazine reports, and from the statements of the Russians at meetings—clearly indicates that they have a determined program to advance beyond even the launching of satellites.

The CHAIRMAN. Doctor, could you elaborate on the nature of the advanced Vanguard program?

Dr. HAGEN. Yes, sir.

The present Vanguard vehicle has a capability of putting a satellite which weighs about 21 or so pounds into a stable orbit around the earth. The total weight that the present Vanguard can put in orbit is about 75 pounds. That is the 21-pound satellite and the 55-pound third stage rocket casing both go into orbit, giving about 75 pounds in orbit.

Now the advanced Vanguard is a modification of the present Vanguard, principally an improvement in the operation of the third and the last stage. This would actually make it possible to double the weight one can put into the scientific package and thereby greatly increase the amount of scientific work that can be done. The advanced

Vanguard would place a 40 to 50 pound satellite in orbit and, of course, the third-stage rocket as well, or a total of about 100 pounds.

The CHAIRMAN. Are there any tests proposed in the future?

Dr. HAGEN. Of this vehicle?

The CHAIRMAN. Yes.

Dr. HAGEN. We expect before the end of the Geophysical Year to run at least one test which will demonstrate this capability.

The CHAIRMAN. Do you have any idea as to how much weight it will be?

Dr. HAGEN. The weight we expect to put into the scientific package is about 40 pounds.

The CHAIRMAN. These rockets have many capabilities, have they not?

Dr. HAGEN. Yes, sir. The Vanguard vehicle was designed from scratch as a space vehicle. It has the most advanced design in all of its stages. It is then capable of being combined with other vehicles for space research by employing larger boosters. For example, replacing the Vanguard first stage with a larger first stage, one can think in terms of very much larger payloads or in terms of having the vehicle take the payload away from the earth and explore farther out into space.

The CHAIRMAN. Is there any proposal for trying to project one to the moon?

Dr. HAGEN. There is no authorization for the Vanguard organization to do this. The only authorization is one that was reported some several months ago when the Air Force had undertaken such a project employing some parts of the Vanguard vehicle. I do not feel free to discuss their method of doing it, however, in great detail.

The CHAIRMAN. Will you state why you feel that either a commission form of an agency, or this board, full-time board that you mentioned, is preferable to the organizational setup of the pending bill.

Dr. HAGEN. The principal reason is that this will be an extremely busy group, that a great deal of their attention will be required. The full-time board, then, would devote itself entirely to this aspect of the work. Their life's work would be to see that our program in space research and exploration would be well thought out and well conducted.

Another point is that the full-time board would not have the same conflicting interest that the parttime board, I think, is bound to have. It is difficult to have a group so chosen that they can unselfishly serve two masters.

The CHAIRMAN. Do I also infer it to be your opinion that this gives a better opportunity for the assumption of responsibility and for decisions to be carried out quickly and effectively?

Dr. HAGEN. That is basic.

The CHAIRMAN. The question of responsibility is the uppermost question in anyone's mind.

Dr. HAGEN. Yes. This group will bear a heavy responsibility and one of the things that I believe is taken care of in the bill is that the necessary authority and ability for direct action be given to both the director and the group.

The CHAIRMAN. Would it be fair to say that once the agency is established it probably will be absorbed with activities within the Government in the future?

Dr. HAGEN. Yes, sir. In order for this group to function and to make the immediate progress that it must make, there certainly would have to be an absorption of some existing functions.

The CHAIRMAN. In other words, we cannot have research activities distributed among several departments and agencies. Sooner or later we have to come to a coordination, or call it centralization; is that right?

Dr. HAGEN. To a certain extent that is right. I do, however, believe that the other agencies or departments must carry on research to a point in order to support the basic research, to support their peculiar activities, and that the research carried on in other activities might be very broad and not precisely directed.

The CHAIRMAN. Of course, that can be worked out. You mean the Defense Department?

Dr. HAGEN. For example, the Defense Department.

The CHAIRMAN. Those matters can be worked out by understanding minds cooperating as such.

Have you an opinion of the level such an agency; should it be on the level of the National Security Council in relation to the President?

Dr. HAGEN. I would hope that the agency would be of such a level that the director would report to the President through the Security Council.

The CHAIRMAN. Or if there is a commission, the commission?

Dr. HAGEN. Yes, the director representing the commission, or the chairman of the commission.

The CHAIRMAN. In connection with this field—I call it field for broad purposes of description—and projecting your mind as to the importance in the future, is it of sufficient importance that it should have quick access to the Commander in Chief?

Dr. HAGEN. Yes, sir; I certainly believe that.

The CHAIRMAN. Mr. Brooks.

Mr. BROOKS. Doctor, in reference to the board which the chairman has been inquiring about, if you have a full-time board, meeting at all times, what then is the need for having a director?

Dr. HAGEN. The director would bring together the divergent thoughts of the board when he had gained an agreement on a policy and direction for action; he would then act as the executive agent in carrying out this action.

Mr. BROOKS. You would have purely an advisory board, and the director would try to get their composite views. Then after he had gotten them he would go ahead and act as a director?

Dr. HAGEN. That is a method of operation.

On the other hand, I see no reason why the director could not assign certain areas of policy study and planning to the members of the board.

Mr. BROOKS. In other words, the director would employ members of the board?

Dr. HAGEN. You might state it that way, yes.

Mr. BROOKS. This is what I am concerned with.

If you are going to have a board of 17 members meeting at all times and that board selects a director and then the director has the authority to employ members of the board, are you going to have a setup that will be workable?

Dr. HAGEN. No, sir. I was talking about a different thing when I answered your question. I was thinking in terms of the smaller, full-time group. I believe your question concerns the board as it is proposed in the bill.

Mr. BROOKS. Now, a smaller group would be more like a commission or council of five people.

Dr. HAGEN. Yes, sir.

Mr. BROOKS. They would select a sitting manager, that sort of setup.

Dr. HAGEN. Or, conversely, the director and chairman of this group would be selected by the executive office of the President.

Mr. BROOKS. The director and chairman of the board would be selected by the President rather than by the board?

Dr. HAGEN. Yes, sir.

Mr. BROOKS. Then the director would have the authority to employ any of the members of the board? The board would establish its policy?

Dr. HAGEN. The board, as a group, would establish the policy for the agency.

Mr. BROOKS. But would have no executive authority?

Dr. HAGEN. Except as that executive authority in areas is delegated to it by the chairman. The chairman of the board would have executive authority to carry out the policies of the board.

Mr. BROOKS. Then what would the director have?

Dr. HAGEN. I think of the director as the chairman of the group.

Mr. BROOKS. The chairman of the board would be the executive director?

Dr. HAGEN. Yes, sir.

Mr. BROOKS. He would be chairman of the board legislatively and executive director in addition; he could employ any members of the board?

There, though, are you not having a situation of divided responsibility in the executive branch in the execution of the program?

Dr. HAGEN. I did not believe so. I felt that the principal function of those on the board is to establish policy for the group. I did not believe that the assignment to them of other functions in the planning of the agency would interfere with them as a policymaking group, sir.

Mr. BROOKS. I am not trying to confuse you, but it would seem to me with a small group to legislate, so to speak, on the objectives of the program and then having the director as chairman to carry out that program, and authority to employ the others, you are combining the whole thing and you might as well set it up as a board to hold both legislative and executive responsibilities. What do you think of that?

Dr. HAGEN. The point that I was really getting at there was this—and this was in answer to an earlier question—that I believed the members of the Board should not be responsible to the Director for determining policy, but to the higher authority who appointed them.

Mr. BROOKS. The President?

Dr. HAGEN. The President, let us say, and that they as a group determine policy.

Now, the other functions that the Board members might perform in carrying out the planning of the Agency, I would believe, should not interfere with their stature in determining policy.

Mr. BROOKS. They would still be responsible to the President for the proper performance of these other duties, too; would they not?

Dr. HAGEN. Perhaps I have confused the issue. I did not believe that it was necessary that they do so.

Mr. BROOKS. Well, I am not going to pursue that. I just wanted to get your ideas on it. But I did want to ask you about this Vanguard organization.

You disturb me a good deal when you say unless some action is taken the Vanguard organization will go to pieces at the end of this year.

Dr. HAGEN. That is true. We have essentially completed a phase of the job on which we are working. In this work a long lead time is required to get experiments prepared and vehicles designed and built. We are now essentially completing the building of the vehicle and have before us one phase—to attempt to launch the remaining vehicles successfully. We are, in other words, phasing out certain phases of our work.

Mr. BROOKS. You are completing your mission successfully. You need the go sign at once, then?

Dr. HAGEN. Yes, sir.

Mr. BROOKS. If you get the green light right away, will that be ample time to continue your program, or even then will there be an intermission?

Dr. HAGEN. Even then there will be a slight hiatus, but it is not too late.

Mr. BROOKS. So the failure to act today is already creating some delay in your program?

Dr. HAGEN. That is correct.

Mr. BROOKS. I want to say to you today, sir, that I think you ought to be given the green light, that there should not be any interruptions in your program in the development of the satellite.

Now, what about the Jupiter-C? Is it in the same status as the Navy program?

Dr. HAGEN. The Jupiter-C is in a slightly different status. It is based on an assisting military vehicle, the Redstone. It was brought into this program as a backup vehicle when we became concerned about our abilities to match the performance of the Russians after their October and November firings. This was an insurance program.

Mr. BROOKS. I think we made a serious mistake in jumping from the Jupiter-C program over into the Vanguard program suddenly in 1956. Since that has been done you have done a successful job, but it was very doubtful to me at times that you would be successful.

Since you have done it, we would be making a serious mistake now in letting your program lapse or even subside for a while rather than be pushed ahead. Do you not agree with that?

Dr. HAGEN. I certainly do.

Mr. BROOKS. What authority do you need to go ahead with that program?

Dr. HAGEN. The authority would have to come from the office which has recently been set up in the Department of Defense.

Mr. BROOKS. From Mr. McElroy, the Secretary of Defense?

Dr. HAGEN. Or Mr. Johnson's group in the ARPA.

Mr. BROOKS. The new Agency?

Dr. HAGEN. Yes, sir.

Mr. BROOKS. I, for one, hope the new Agency does not delay in giving you the authority.

Now, you say the maximum weight you can carry, usable weight, would be 40 pounds in the Vanguard? Now, does not the Vanguard have greater possibilities than the lifting of 40 pounds of usable weight?

Dr. HAGEN. Not in its present form. It is part of our planning to make this Vanguard vehicle capable of putting even larger satellites in stable orbits. To do that, however, we would have to modify the first stage. We have considered this and we know how to modify the first stage to put a few hundred pounds into an orbit.

Mr. BROOKS. That was the real reason for the switchover to Vanguard, because we thought it had greater possibilities of developing a capability of carrying a much heavier satellite; that was it, was it not?

Dr. HAGEN. Yes, sir.

Mr. BROOKS. And will we be able to develop that Vanguard to the point where it will carry a missile of a thousand to 2,000 pounds in usable weight?

Dr. HAGEN. Yes. What is required is an orderly progression to take the first step, the improved Vanguard I mentioned earlier, which will bring us up to 40 pounds, and then to replace the present booster, which uses the GE engine, with a larger booster. If this were done we could put a satellite that weighs anywhere between two or three hundred and a thousand pounds in an orbit around the earth.

Mr. BROOKS. When are we going to start work on a missile that will carry a satellite of 2,000 pounds so as to offset the science and the effect of the Soviet missile?

Dr. HAGEN. There are presently in existence plans which I should not discuss in detail in an open meeting, to make even larger satellites.

I would like, however, at this time, to make a short point and that is this: The weight of the satellite is not always the important number. The important thing is the quality of the experiments and the weight and perfection of miniaturization of your equipment.

I sincerely believe that we have techniques in this country, and are using them in the Vanguard effort, which will make it possible for us to put much more equipment in a package of a given weight than our competitor. So, again, it is not really the total weight that counts, but the number and quality of experiments, and the degree to which you have miniaturized your electronics.

Mr. BROOKS. But the ultimate is to increase the size of your satellite and to increase the ability of the satellite to carry, we will say, the weight of a man?

Dr. HAGEN. Yes, it is.

This brings out another point that I would like to lay a little emphasis on. All of us believe that the ultimate goal here is to put a man in a space vehicle. What that man will do when he gets there is something that needs to be determined on the plane of a policy and a plan.

However, the important thing is this: We should not allow our feeling of competition with our present adversaries to make us lose sight of our belief in the dignity of the human soul, in the rights of individuals. We should, therefore, never subject an individual to almost certain destruction when we have the capability of putting into satellites experiments which will determine the exact nature of outer

space—the effects of the primary cosmic rays, for example, and the effects of extreme radiation upon the human body—and when we can also experiment in the laboratory to determine the mental and physical effect of weightlessness for a certain amount of time on the human body. We should do all of these things before we put a man into a vehicle and shoot him off into space.

Mr. BROOKS. I think you have made a splendid statement in that respect. I agree with you fully.

Now, out of your 13 to 15 vehicles, how many have you fired thus far?

Dr. HAGEN. I did not bring the count with me. There have been test vehicles through No. TV–4, which means that there have been 6 test vehicles fired, the last 1 having in its nose the small test satellite that is now in orbit. We have ahead of us 8 vehicles capable of putting up the large IGY spheres.

Mr. BROOKS. When are you going to fire the next one?

Dr. HAGEN. The newspapers, I understand, are reporting that it will be Thursday of this week.

Mr. BROOKS. You have not decided it, have you?

Dr. HAGEN. No, sir; I have not, but I will state that it is going to be very soon.

The CHAIRMAN. Do you challenge the probable accuracy of the newspapers?

Dr. HAGEN. I think we can just wait and see.

The CHAIRMAN. You said in the near future?

Dr. HAGEN. In the very near future.

The CHAIRMAN. That does not mean weeks?

Dr. HAGEN. That does not mean weeks.

Mr. BROOKS. So we can expect some action down there at Banana River soon?

Dr. HAGEN. Yes, sir.

Mr. BROOKS. Yesterday in a newspaper interview you referred to the fact that the Vanguard satellite would probably be up 200 years before it comes down. Is that your mature judgment?

Dr. HAGEN. It is. It took us a long time to arrive at that conclusion, because the orbit is so stable that the changes in it are hard to measure. The mere fact that the changes are hard to measure indicates the lifetime is going to be long. In the month the satellite has been in orbit we have closely observed the rates and the period at three well spaced times, and from that have been able to draw a firm conclusion that the lifetime will be at least 200 years.

Mr. BROOKS. Is that because of the peculiar ellipse that orbit has? Is that one of the reasons?

Dr. HAGEN. The reason for the long lifetime is that the perigee, or least distance from the surface of the earth, is 400 miles. This is, the important number in any satellite orbit, because the thing that makes the orbit decay is the drag in the residual atmosphere. Now, the density of the atmosphere decreases rapidly as you go up from the earth. So the larger you can make the perigee distance, the longer the lifetime is going to be.

Mr. BROOKS. And the perigee is not changing a great deal, then?

Dr. HAGEN. It is staying very, very constant.

Mr. BROOKS. Now, what are we going to do with a satellite up there 100 years or 200 years from now?

Dr. HAGEN. I like to think that our grandchildren and our grandchildren's children are still going to make use of that satellite. It has in it a small radio station operated by solar cells; that is, the electricity is generated in the satellite by the sunshine.

As times goes on we will use the perturbations in the orbit of this satellite for determining the shape and size of the earth and for measurements on the density of atmosphere and the way that density varies with the activity of the sun. Our descendants will be even more adept than we are in observing and in interpreting these things, so it is hopeful that this will be of use to mankind.

Mr. BROOKS. You do not have any serious thought that that radio is going to be operating 200 years from now, do you?

Dr. HAGEN. I would be very hesitant to make a prediction as to how long that radio will operate, but I believe it will operate for a very long time.

Mr. BROOKS. Do you think our descendants will be blessing you rather than abusing you for putting a satellite up there for 200 years?

Dr. HAGEN. Provided they are not members of the Federal Communications Commission and concerned about the radiation coming down.

Mr. BROOKS. Are we not making some effort, though, to be able to bring those things down so that satellites won't be running around this earth here for 200 years uncontrolled and perhaps a real menace to us?

Dr. HAGEN. It does have great significance to those of us in the program. Space will be filled with deadened, useless satellites after a while. This is going to constitute a menace in more ways than one. We are considering ways and means of bringing these things down. Now, that is not an easy job. You have something moving at 5 miles a second, several hundred miles from you, and you must shoot up a missile to destroy it.

However, you do not bring it down. Even though you break it into small pieces, these small pieces will still circle the earth in orbits. They will experience a greater net drag effect and in time will be cleaned out, but the point is that once you put something in orbit around the earth it is a most difficult thing to remove it.

Mr. BROOKS. It would seem to me, then, that that is one serious concern the world should have, that no nation place uselessly in orbit satellites and parts of satellites to run around this world for several hundred years which will be a constant and serious menace to anyone who lives on earth.

Dr. HAGEN. Yes, sir; that is true. I believe there should soon be set up an international commission, or at least there should be a conference on an international basis to establish, by treaty if necessary, limitations on what one can put out into space and what kind of radio transmitters one can put in these things.

Mr. BROOKS. That is an almost immediate need, is it not, because every time a nation puts up a satellite that menace increases; is that not true?

Dr. HAGEN. That is true. The number of satellites that can possibly be in the air in another year or two is counted far beyond the fingers on your two hands.

Mr. BROOKS. That is what I am afraid of.

The CHAIRMAN. Mr. Metcalf.

Mr. METCALF. Dr. Hagen, in your response to some of the questions the chairman was asking about the organization of the Commission, a Director, or these various setups that we can have, I think you made it very clear how in your opinion this should be organized.

But I do not believe you commented on one of the proposals that we have a Secretary of Science and Research in the President's Cabinet. I wonder if you will comment on that.

Dr. HAGEN. Sir, I think it would be a very fine thing for science in this country and, therefore, for the country as a whole, to take such a step.

We are living in a technological age. Our very existence depends upon our continued advance in science and technology. I am sure it will become more so as time goes on. Just as you now have a Secretary of Commerce, I do believe that we would all benefit by giving science the stature of having a Department of Science.

Mr. METCALF. You made made some comment about the fact you do not think all the research programs should be removed from the various agencies, but one of the proposals we have is that the Secretary of Science and Research take Commerce, Weather Bureau, Agriculture, the testing for better production of seed grains, all of these things. If the Department of Science and Research is created, would you leave those agencies down there?

Dr. HAGEN. On each one you would have to make an individual decision, but in each one I think you would have to take the bigger pieces.

The point I tried to make earlier is this: that in any one of the other departments, for example the Defense Department, in order that the Department not become sterile in the field, there must be within it a group concerned with basic science and scientific research. The Department, however, could call on other agencies.

Mr. METCALF. And the application of all research to various agencies such as the Department of Agriculture, which would have to have some research men in the Department to make application of the basic research in the other agencies?

Dr. HAGEN. Yes, sir; that is correct.

Mr. METCALF. You mentioned that there was clear evidence of a determined Soviet program on space beyond satellites.

I wonder if you can expand both on the clear evidence and the kind of program for space beyond satellites?

Dr. HAGEN. I will restrict my expansion to what I have read in the newspapers and have gotten from talking with Soviet scientists, and I think even that brings clear evidence.

At the time of the IGY meetings here in Washington last September, the Russians sent over their top rocket and satellite people. They mixed with the representatives of the other countries who were there, in particular the people who were working on this thing in the United States, and talked rather freely with them.

At that time it was made clear to us by the leader of the group that the Soviet program was a strong program; that it had a lot of backing at home, and that it was then their intention to attempt to launch satellites at the rate of one per month. Now, if they have carried through with their intentions, they have not been successful in putting satellites into obit at that rate. But the indications are certainly that

they had the intention, and they most probably have tried. They have within the Soviet Union, and I do not remember the exact name of the organization, a commission on astronautics which is set up to guide work of this kind in terms of long-range planning and specific guidance on the immediate program. In this respect they are ahead of us in the planning. This is the kind of thing to which I referred.

Mr. METCALF. In response to one of the questions directed to you by the gentleman from Louisiana, you said the ultimate goal is to put a man in a space vehicle. Is that what you mean by the Soviet program for space beyond the satellite?

Dr. HAGEN. Yes. And this is one specific comment I would like to make about the bill before us: I believe that in time one of the principal things that will be done in space is exploration. Now, exploration is not specifically assigned as one of the responsibilities of the agency in the bill. I think none of us could today be specific about the precise kind of exploration that would be done, or the possible benefits that would come. We do know that we are going where man has never been before, and it would be foolhardy to predict the exact benefits that will be derived. You may be sure, however, that there will be benefits.

Now, in the beginning this exploration can and must be done by unmanned instrumented vehicles. But the time will come when we will want the intelligence of a human being in place to direct whatever is being done.

The CHAIRMAN. What about this language:

> * * * solution of, problems of flight within and outside the earth's atmosphere and that provision also be made for the development, testing, and operation for research purposes of aircraft, missiles, satellites, and other space vehicles, manned and unmanned, together with associated equipment and devices.

Would you say that that language covers exploration in space?

Dr. HAGEN. I did not believe it did. Perhaps I did not read it carefully. The interpretation I placed on it was that the bill would authorize the development and design of a vehicle to do this kind of thing, but not specifically the carrying out of the exploration. This is the point I want to make.

Mr. METCALF. As I understand your testimony, you are convinced the Russians have a master plan for exploration into space beyond putting satellites into orbit, and it is up to us to get a commission or some govermental agency together to put together a master plan for us to get ahead of them in space exploration.

Dr. HAGEN. Yes, to give considered judgment as to how far we should go in this area and then to formulate a good constructive plan for achieving the goal that is determined.

Mr. METCALF. I gather from your testimony, on the basis of the priorities you were given, the appropriations you were given, and the limitations that were put upon you in the Vanguard project, we have no apologies to make for the success of that project.

Dr. HAGEN. Yes. I brought this matter up to point out that if we do go into a program of this sort it is bound to have the same appeal to the country as a whole as the satellite program had. And if this is so, we should benefit by the mistakes made in the satellite program, should recognize that aspect of the program and recognize that therefore it must have adequate funding and adequate priorities in the very beginning.

Mr. METCALF. Had there been such an agency as is proposed in the several pieces of legislation, you would have had the flexibility and the authority to go to some secretary or director and take into account the new urgency that occurred last October?

Dr. HAGEN. Yes, sir. That being so, there would have been recognition at the time of the tremendous public appeal of a program of this sort. The psychological impact of this was not fully understood at the time we were planning our program.

Mr. METCALF. Thank you, Mr. Chairman.

The CHAIRMAN. Doctor, will you submit to the committee your suggestions as to how you think the bill can be improved?

Dr. HAGEN. Yes, sir.

I have just 2 or 3 in the main. The aim back of the bill and the method in which it proposes to achieve that aim, I think, is very fine.

There is, however, the point I made earlier about not identifying exploration specifically as an objective. This, I believe, is a point which would strengthen the wording in the bill.

On page 4 there is a point where I feel I might ask a question and perhaps offer an opinion. At this point it is stated in the bill:

> The Chairman of the Board shall be designated from time to time by the President from among the members appointed under subsection (a) (2) of this section * * *

The Chairman of the Board then is limited to those members of the proposed Board who come from outside the Government. Now, as a long-time Government employee, I do not see the reason for this restriction. You will find in the Government very conscientious and capable people who are not only scientists, but who have executive ability, and I believe that they could be among the possible choices for Chairman of the Board without being concerned about a conflict of interest. I would, therefore, recommend that this restriction on the choice of Chairman of the Board not be in the bill.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. Doctor, do you agree our country is still ahead of the Soviet Union both theoretically and experimentally in most scientific and technological fields?

Dr. HAGEN. No, sir; I do not think that I could make that statement. I believe we are ahead of them in a great many things, but in other areas they are ahead of us.

In the areas of instrumentation—and perhaps you are referring to the instrumentation of such things as satellites—the devising of a sophisticated scientific experiment and the preparation of this experiment for placing in a thing like a satellite, I believe we are ahead of them. On the other hand, they are certainly ahead of us, as was indicated quite clearly, in the capability of putting X number of pounds into a satellite orbit.

Mr. NATCHER. I understand from your testimony the average salary of the top 5 scientists is $12,000. Do I understand that correctly?

Dr. HAGEN. Yes, sir. The average salary of the 5 top individuals working for me in Vanguard is $12,000.

Mr. NATCHER. I certainly agree with you, Doctor, that salary is too low. One of the things that we should do in this country, I believe, is to recognize our scientists from the standpoint of paying them what they are entitled to.

In the Soviet Union today, scientists are looked up to as well as generals and admirals. They occupy a position of great importance at the present time. Is that your information?

Dr. HAGEN. Yes, sir; this is the information that I have from what I think are fairly authoritative sources. At the present time in Russia a successful and producing scientist has a choice position. He is rewarded not only by respect and the benefits which are given to one's self, but he is also rewarded in a salary that is commensurate.

Mr. NATCHER. Doctor, a scientist employed by the Federal Government today is working under extreme handicaps and pressure. You agree on that?

Dr. HAGEN. I think a great many are, yes.

Mr. NATCHER. In fact, isn't it just a little harder at the present time to work with the Federal Government than it would be to work for some company in private enterprise, with the pressure on as it is?

Dr. HAGEN. Well, it would be difficult to substantiate that statement in detail. I think on the average, if you take people as a group, this might be true, but I am sure someone could bring up the exception which breaks the rule.

Mr. NATCHER. As I understand it, the proposal before the committee calls for the space board not to exceed 17 members. In your opinion, this particular number is too large? Is that correct?

Dr. HAGEN. I believe a smaller number would be a more manageable group, and agreement could be obtained on matters of policy much more efficiently and effectively.

Mr. NATCHER. Assuming the number is changed to 5, how should the 5 be allocated as far as the agencies of our Government are concerned, the military services, and scientists? What, in your opinion, should be the allocation, assuming the number is five?

Dr. HAGEN. I hadn't thought in terms of allocating them by position in Government. I would think the individuals would be chosen for their ability and their experience in the field, rather than to be chosen as representing some agency of Government or industry.

Mr. NATCHER. Assuming the number is 5, should the military services have 1 member or more than 1 member, Doctor?

Dr. HAGEN. Well, I would certainly think, and hope, that at least one of the members would come out of the military departments. The reason for this is that there is bound, always, to be a relationship between the functions of this Agency and of the Department of Defense. There needs to be a cross-organization, and a common use of tools and of equipment. On the other hand, a great many of the advances that I am sure will come out of this effort will have military use or value, or can be slanted toward the better defense of the country.

At the same time, the military will have hardware which will be of use to this Agency. Therefore, there will be a close relationship between the Agency and the military. I would think it would be highly advantageous to have in the Board people drawn from the military side, from the Department of Defense, who are aware of the capabilities and potentialities of groups in the Department.

Mr. NATCHER. Doctor, in your opinion, does science deserve a place in the Cabinet at the present time?

Dr. HAGEN. My earlier answer to that was "Yes."

Mr. NATCHER. How long will it be, Doctor, before we can take one of our satellites out of orbit, or can we do it today?

Dr. HAGEN. You mean to remove it. We cannot do it today. I think if one were—let me put it on a personal basis, it is easier then. If I were assigned the task and given the necessary tools to try to do this, I would expect it to take something on the order of a couple of years, at least, to be at the point where I would make the first test of the technique.

Mr. NATCHER. Thank you, Mr. Chairman.

Mr. BROOKS (presiding). Mr. Sisk.

Mr. SISK. Doctor, a little while ago you discussed the fact that we might ultimately have quite a flock of satellites in orbit. There was some discussion of the menace involved. From what I have been told, there is quite a bit of space out there, quite a bit of room involved.

To what extent do you consider even a substantial number to be a menace. What do you mean? A menace to those of us here on earth or a menace to later space travel? Would you interpret it a little further, if you are in a position to do so at this time?

Dr. HAGEN. I don't in any way consider it a menace to future space travel. As you say, space is a tremendously big place, and the chance of colliding with an odd satellite in the future is bound to be very, very small. But I think the astronomers should be concerned about the corruption of space with these things. Astronomers are tidy people and they like to keep track of everything in space. It is going to present a great problem to know what each of these things is, especially those large enough to register on their photographic plates.

The principal concern I would have, however, has to do with the defense of the country. You can only guess that as time goes on, we will be more and more concerned about the possibility of missiles coming from somewhere on the other side of one ocean or another. We will have to do the same kind of warning devices that we have today for planes, to identify these things as they come along. The distinction, for a quick look, between a satellite going overhead or coming at you, and a missile or a meteor is not very great. It will take a careful look to determine in a very short time whether the object you see coming is some old satellite, an ICBM coming from across the water, or a stray meteor coming into the earth. However, we are going to have to do this. Filling the air with a great many dead satellite bodies is simply going to make that task extremely difficult.

Mr. SISK. Any opposing nation or any nation with whom we might be at war, of course, would be confronted with exactly the same situation, because certainly they will have instrumentation, and will have their radarscopes, and so on, too.

Dr. HAGEN. Yes.

Mr. SISK. In summation, then, the menace which you discussed with the gentleman from Louisiana has to do with the potential threat to peace?

Would that be a proper summation of it?

Dr. HAGEN. I think that is a proper statement, properly interpreted. It has to do with the national defense, and the desire to keep the situation as cleanly defined as it can be, so that there can be no accidental starting of a war, for example, by an improper interpretation of the meaning of something you see coming over.

Mr. SISK. Doctor, I understood you to say earlier that you did not feel we were making proper utilization of our scientific and engineering knowledge in this country.

In what way do you see application in the proposed legislation to improve that ultilization?

Dr. HAGEN. Among the great improvements that could come about could be the consolidation of the effort under one agency or at least consolidation of the planning of the effort within an agency so there can be more effective use of manpower. We would then get away to some extent, I trust, from the situation where we have groups of people with certain capabilities built up here and there throughout the country and being held against the chance that a piece of work or a contract were common to the group. The number of scientists and engineers that we in this country are holding in that state, I am sure, is a large number, a fair percentage of the total of top capability.

Mr. SISK. You do not anticipate a consolidation of the various teams of scientists under a program of this kind, do you?

Dr. HAGEN. No, I meant more the consolidation of the purposes, so that plans would be clearly made for carrying the work forward and the various groups could then be intelligently brought together and applied to the different parts of the plan. To a large extent today we are operating without that kind of plan. It is a matter of improvement in the use of people through planning their movements rather than having each go off in his own direction, hoping that altogether eventually we will bring forth the thing desired.

Mr. SISK. You have no particular criticism, or maybe you do, as to the divisions of these various teams. For example, a team operating at the Redstone Arsenal, your own particular team, a team in Los Alamos or somewhere else. Do you feel that tends to expedite the work, or do you feel that that division possibly breeds delay?

Dr. HAGEN. The answer depends upon the answer to another question, and that is: What degree of planning has been done to begin with? Certainly if the planning is well done, the distribution of the effort in 2 , 3, or a half-dozen different places will not adversely affect the efficiency of carrying out the plan. The plan itself is the thing which determines the efficiency.

Mr. SISK. So that this high-level agency, then, will actually become a coordinating group, to coordinate the work of the various teams; is that a proper analysis of it?

Dr. HAGEN. I would like to believe that, to a degree, this is the way it would operate. However, the Agency should have its own laboratories, field stations, and launching facilities. It should be possible for it to be a self-contained agency. However, in order to prosecute the work in the most efficient manner today, they would have to go to other assisting agencies to carry out some of the projects.

Mr. SISK. Doctor, you made the statement a little while ago that Russia had been able to develop an engine with sufficient thrust to project a much larger payload, object, or otherwise, into space. You indicate they are well ahead of us in that particular feature. On the other hand, you felt when it came to instrumentation possibly we were ahead of the field.

Why would you say that? How do you know that? Are we simply alibiing a little bit? In this, I don't mean to be critical about you. I recall last fall, immediately after the Russians launched the sputnik, when I was asked questions in certain meetings, I said, "Yes, we will have a satellite in space shortly, and I am sure ours will be better instrumented."

When I sat down and analyzed it, I think I was simply alibiing. Are you prepared in an open meeting to say on what you base your statement?

Dr. HAGEN. Yes. I am not afraid to state on what I base the statement. It is built upon something that is intangible—upon my observation of the Russian scientists, while they were here in this country, upon watching them to see what they most deeply admired, in what things they showed the greatest interest. They most admired and showed the greatest interest in the experiments we were preparing and the highly sophisticated miniaturization processes that we were using to put a lot of experiment into small space. This brought out from them a great interest. I believe you can take this as an indicator that they were seeing something they themselves didn't have.

Mr. SISK. One other thing that has been of some concern to me, Doctor, has been a position of follow-the-leader we have permitted ourselves to reach. Are we in a situation today, in this space and satellite program, and, of course, it has its military application in the ICBM and IRBM, of depending almost wholly upon political initiative alone?

Why are we in a position today where we are so dependent upon political forces, upon the governmental end of it, let's say, to move ahead? I am thinking now of how we developed the airplane, and how we developed many other things that put us ahead in the world. Why do we find ourselves in this position today?

Dr. HAGEN. That is an awfully difficult question to answer. I think historians and philosophers many years from now will debate the point. But for many reasons, we in this country were somewhat adverse toward discussing space travel or taking it seriously. It was considered to be comic book material.

We didn't appreciate its full impact. The real answer, I think, to your question goes back to the matter that I mentioned before, of a proper plan. I believe we will get away from the position of following the leader—and there is a strong tendency to do this—wherein if the other fellow makes an advance you try quickly to equal or better it.

For our own good it would be much better to let the other fellow go his own way and for us to recognize that this space age has opened a new frontier and to plan what we, as a nation, want to do, and then set about doing it and not worry about when the other fellow makes his steps. If we make a real plan and make it in such a way that one step logically leads to another, we will get there in the end much quicker.

Mr. SISK. I am happy to hear you say it. That is the thing which is becoming of increasing concern to me, as I listen to witness after witness here, and we read newspaper articles. Seemingly, today, we do things simply because Russia or some other power has done

them. I think some of us, at any rate, are slipping a little bit in our incentive idea or in taking the initiative in going ahead and planning our own program and usng our own judgment to proceed as rapidly as we can toward the objective which we hope to achieve. Possibly we depend entirely too much on the other things.

You, as a leader in the field, have certainly given this some thought down through the years. Isn't it true, Doctor, that you were thinking about these things as well as other scientists a long time ago?

Dr. HAGEN. Yes, sir; that is true.

Mr. SISK. Thank you very much, Doctor. I appreciate your comments.

Thank you, Mr. Chairman.

The CHAIRMAN. Doctor, is there any consideration among scientists here or abroad of an extension of the International Geophysical Year?

Dr. HAGEN. Yes, sir, there has been a discussion among scientists and recognition of the need and the value for such an extension. It has been a very, very rewarding and pleasant experience to see this concerted action by people in many countries of the world which has brought out so many things of value. I think we should recognize that value and perhaps extend the effort.

The CHAIRMAN. Do you know of any efforts being made along that line?

Dr. HAGEN. I can't say for certain what the effort is, whether there is indeed a formal action being planned. I know there have been discussions.

The CHAIRMAN. But is it your opinion that our Government, through its proper agency, should enter into discussions if not negotiations with other countries, having in mind an extension of the International Geophysical Year?

Dr. HAGEN. I would highly recommend it, yes sir.

The CHAIRMAN. A good, healthy climate has come out of it, has it not?

Dr. HAGEN. Yes, sir.

The CHAIRMAN. And certainly the opportunity for that climate to continue through an extension might produce some beneficial results?

Dr. HAGEN. It is one way of heightening the understanding that might exist between us and any other nation that is in the organization.

The CHAIRMAN. I am not looking at it from the angle of conflicts or tensions that might exist, but the broader angle. There is no harm from anything that is good.

Dr. HAGEN. Yes, sir.

The CHAIRMAN. Mr. McDonough.

Mr. McDONOUGH. Dr. Hagen, I appreciate the information you have provided the committee this morning, and the fact that you have had experience in one of our more sophisticated thrust engines, the Vanguard.

I am curious to know if our program on developing a maximum thrust is the design of the engine or the fuels that are used. Which of the two is the more difficult to produce?

Dr. HAGEN. I think the answer to that would be dependent upon to whom you were talking. The chemical fuels people would think their job is harder, and the materials people would think theirs is harder. The difficulty is this: We are using about the highest energy fuels we can lay hands on today, safely. There are newer, more

exotic fuels which are capable of releasing more energy per pound as they burn, but there are difficulties that have to be overcome in handling these fuels. I should say that in this chemical fuel area there is a limitation beyond which one can go no further. To get even higher impulses we will have to get away from chemical fuels and employ some nuclear processes.

In making any advance in rocket propulsion, necessarily involved are problems of materials in the combustion chamber and in the nozzle of the rocket.

These materials have to withstand a higher and higher temperature and have to withstand the flow of hot gases at high velocity. This is the serious limitation in the engine itself.

Mr. McDONOUGH. But we are working on fuels that will provide greater propulsion than those we have used up to now. You say there is a limitation on the chemical fuels, but do you mean a limitation as to their maximum expansion and volatility and their ignition, the immediate ignition of them? What are the limitations?

Dr. HAGEN. The limitation is on the amount of energy you can get by burning a pound of whatever the fuel is.

Mr. McDONOUGH. Then there is a limitation on the full use of that sudden explosion in order to get the thrust, isn't there?

Dr. HAGEN. I think that problem has been fairly well worked out. The efficiency of the modern rocket engine is quite high. I can't quote the figure, but it is high compared to the efficiency of earlier engines.

Mr. McDONOUGH. We know Russia has a greater power thrust than we have, isn't that true?

Dr. HAGEN. That is right.

Mr. McDONOUGH. Is that because of the fuel or the rocket design of the engine?

Dr. HAGEN. It is difficult to say. It could be either. That is, one could take the fuels and methods that we now use and, by building a bigger engine, get the thrust that the Russians must have had to do what they did.

However, that whole problem would be greatly simplified if a more exotic and a higher energy fuel were used. Which approach the Russians used we, of course, have not been told.

Mr. McDONOUGH. To what extent have we used hydrogen gas as a propellent?

Dr. HAGEN. This has not been used, to my knowledge, to any degree. Ideally it is a good thing to use. One of the ideal propellent combinations would be hydrogen burned with oxygen, both carried in liquid form in the tanks. Herein rests a problem in that the hydrogen liquefies at a very, very low temperature, and there would be difficulties in handling hydrogen in the liquid form. However, this is one direction in which we can and will move to get higher specific impulses out of rockets.

Mr. McDONOUGH. In other words, you don't think we have reached the maximum in the use of hydrogen as a propellant?

Dr. HAGEN. No.

Mr. McDONOUGH. There isn't any other gas that we know of that would expand as quickly, is there?

Dr. HAGEN. Our propulsion people have been studying this problem assiduously for a long time, trying to find chemicals which will, in burning, release larger amounts of energies than those now in

hand. I don't believe they have come up with anything which would be an improvement over hydrogen burning with oxygen. The point I was making, though, is that burning hydrogen with oxygen would increase the specific impulses by maybe 15 or 20 percent over what we presently can achieve. So the increase that we can look forward to in even the best of the chemical fuels is not a great increase. It is on the order of 15, 20, or 25 percent. What we really need, and must develop for really long-range work in space, is an improvement far beyond this. So we have to look at something other than chemical fuels.

Mr. McDONOUGH. Speaking about the design, and presuming that we have the maximum in fuel, is the principle of a rocket engine the use of thrust against the earth into the atmosphere, and against the atmosphere into space after you have left the earth? Is that the principle of it?

Dr. HAGEN. It works against the attraction of the gravitational field. Therefore, the key element in the design of a rocket is to reduce the deadweight, the weight of the tanks, and the engine body, and to put as much of the weight as possible into the payload. The rocket then works against the gravitational field and carries the payload out away from the earth. In the satellite case, once it gets it away from the earth, the rocket has to do another job, and that is to give the satellite a high enough velocity to make it stay in orbit. In a space vehicle going to the moon, most of the energy is required in working against the gravitational field to get it out as far as the moon. There is one other point that you may have in mind, and that is the reason the rocket itself works; this is the principle of action and reaction.

A rocket goes forward for the same reason that a rowboat goes out from under you when you jump from it. The escaping gases have momentum and that momentum must be conserved.

The only way to conserve it is for the rocket itself to go forward.

Mr. McDONOUGH. In other words, the maximum thrust against it is reacted with the maximum thrust toward it, and you have to neutralize that. You are repelling the law of gravity instantly, as quickly as you can.

Dr. HAGEN. What you are doing, in order to get around gravity, is making this reactive force against the rocket equal or exceed the force of gravity, and the rocket then will rise.

There is another point that should be made here and that is that the rocket doesn't work because the exhaust is pushing against the atmosphere. The rocket would work best out in empty space, where it is exhausting into a vacuum. The fact that the atmosphere is there and the exhaust pushes into that actually makes the rocket less efficient. Our rockets work better after they get up out of the atmosphere.

Mr. McDONOUGH. But you must, to get there, push against the atmosphere.

Dr. HAGEN. No, sir; if the atmosphere weren't here, we would get away from the earth easier.

Mr. McDONOUGH. But due to the fact that the atmosphere is here, you must push against it to get away from it.

Dr. HAGEN. It hinders the motion and makes the operation less effective.

Mr. McDonough. You have the resistance at the nose and you have the gravity at the base.

Dr. Hagen. And the effect of the atmosphere on the exhaust is to prevent it from getting out of the rocket fast enough, and therefore the reactive force isn't as great.

Mr. McDonough. Are you familiar with, and are we developing, antimissile missiles?

Dr. Hagen. We mentioned that a bit earlier in a way of talking about an antisatellite missile. The only thing I would care to say this morning is that this is a difficult task but it is not something that can't be done.

Mr. McDonough. If we had an armed spaceship for military purposes, and it was out a distance of 500 miles from the earth where it would be in orbit, how could that armed spaceship shoot an object at an enemy spaceship in space?

Dr. Hagen. The same way that one ship at sea could shoot at another. He would have to do a good navigational problem. He would have to know his motion, he would have to know the distance and the velocity of the target, and when he would have to do a careful calculation of the effect of the attraction of the earth, for example, on whatever it was he shot out. But it would be feasible, for example, to put out a rocket which would travel from point A to point B.

Mr. McDonough. In space?

Dr. Hagen. In space; yes.

Mr. McDonough. Your spaceship will be traveling at, let's say, 18,000 miles an hour, and your power to eject that object from the spaceship to hit another spaceship would have to be at a greater speed than that.

Dr. Hagen. No; it is all relative. It would be much easier to shoot that object away from the spaceship than from the surface of the earth, because the gravitational attraction of the spaceship to the object would be very, very small, owing to the very small mass of the spaceship.

Mr. McDonough. Thank you very much, Doctor.

Mr. Brooks (presiding). Mr. Fulton?

Mr. Fulton. We are glad to have you here, Doctor, and I want to, as a member of the Navy Reserve, congratulate you on your success. The program has been moving according to schedule, and, as you have very adequately stated today, the context of the Vanguard program was that it was a part of the geophysical year, and it was to move on a planned procedure to have implementation to obtain scientific knowledge. It was not in the sky rocket class, nor was it in the lady-out-of-the-gun class either, as has been said here. There is no doubt, is there, that we have, in our United States program, tried a much more scientifically aimed instrumentation, than the Russians? We are really trying for a scientific purpose to find what can be learned from the orbiting of an earth satellite.

Dr. Hagen. Yes; that is correct. The entire emphasis has been upon the scientific value of the experiment.

Mr. Fulton. Under those circumstances, then, it is really unfair to compare our type of program with that of the Russians, as unfair to us to compare ours to theirs as it is to them to compare theirs to ours.

Dr. Hagen. I believe so.

25973—58——22

Mr. FULTON. I say that in all fairness. The question then comes: When did it become apparent to you that the Russians had changed the aiming of their program for the Geophysical Year?

When did they decide, according to your information, that they were doing something else, that they were going to take a chance and get a speedup in order to take a shot at an earth satellite in orbit?

Dr. HAGEN. I think the way to answer that is this: From the very beginning, our program was clear and open. It was openly decided to go into the program. It was openly announced by the President in July of 1955 that we were, indeed, in the program, and he stated our objectives. From that time on, the program was carried forward strictly as a science project in the International Geophysical Year.

The Russian program, on the other hand, was not so openly announced. It wasn't until the conference in Barcelona in September of 1956, I believe, that the Russians made the announcement that they were also officially doing this job as a part of the International Geophysical Year.

(EDITOR'S NOTE: Review by this committee staff shows a series of reports on Soviet satellite plans were published in the New York Times from 1951 on. See our report of May 21, 1958, pp. 204–208.)

I think events have proven that it is fair to presume the Russians started their efforts long before they made their announcement, and their effort was based upon the use of military vehicles which they had in hand at that time and we did not.

Mr. FULTON. So that actually what happened is that we then in the United States participated in the Geophysical Year on a very open, frank, free basis, with inspection being made by the scientists of Russia as well as all other countries, of the equipment that we had in the United States as well as the progress which we were making; is that not right?

Dr. HAGEN. That is correct; yes, sir.

Mr. FULTON. Then the Russians, on the contrary, concealed theirs, and, instead of cooperating on the same, frank, open basis, it became apparent at one time to even our own scientists that we were not receiving their open, free cooperation; is that not correct?

Dr. HAGEN. That is correct. And they did not make an open statement of their intention until this meeting in Barcelona, Spain, in September 1956.

Mr. FULTON. Under those conditions, it seems obvious that, for the defense of this country, there should have been a policy set which would determine what should have then been given to the Russians as a matter of information, and what should not have been given to the Russians. The reason I say that is as soon as it became apparent to our scientists that they were not dealing as openly as we were, and we in the United States then continued on our same open, free and easy way, we weren't being too smart; were we?

Dr. HAGEN. I would like to develop that point a little bit. It is too complex to give a "Yes" or "No" answer. I think it can be argued that the agreement in the IGY was that the experiments themselves, when done, would be freely described, and the results of the experiments would be freely exchanged. The procedures for accomplishing this were set up by the international IGY organization; and they are, in brief, that the results of the experiments are turned in to world data centers and to the international IGY organization in Brussels.

Mr. FULTON. Would you at this point in the record, rather than going into the details, as this meeting is getting late at this point, put in the system used by the IGY in a statement in the record at this point.

Second, would you, with the chairman's permission, put in a report of your entire calendar for the Vanguard project on its association and cooperation with the IGY.

Next would you put in a history as to the correlation of how you have met that calendar to date.

And would you likewise give us a calendar for the future on your stepped-up Vanguard proposed program.

In addition, would you give us an estimate of the various cost factors on your proposed stepped-up Vanguard program.

Likewise, if we could, to see a comparison between the Russian programs and our own programs on these earth satellites from your own point of view.

Next, I wish you would put into the record a glossary or a dictionary of the terms that you have used here of a scientific nature because we on this committee are obtaining the first official use, I believe, of many of these terms that are now being used among scientists.

I would like to ask further that, with the chairman's permission, each witness who has appeared here make his own definitions for his statements and his testimony on these scientific terms that are now becoming current.

(Material requested in the foregoing is as follows:)

1. Requested an explanation of the IGY policy on information exchange. This question was referred to the National Academy of Sciences, and the following letter constitutes their reply.

NATIONAL ACADEMY OF SCIENCES,
NATIONAL RESEARCH COUNCIL
OF THE UNITED STATES OF AMERICA,
UNITED STATES NATIONAL COMMITTEE,
INTERNATIONAL GEOPHYSICAL YEAR 1957–58,
May 9, 1958.

Dr. JOHN P. HAGEN,
Project Director, Naval Research Laboratory, Washington 25, D. C.

DEAR DR. HAGEN: In accordance with your request this afternoon, I am pleased to provide the following information on the data interchange agreements within the International Geophysical Year program.

From its inception, the full interchange of data was recognized as an integral part of the program. Agreements covering the interchange of data appear in formal form in the CSAGI Guide to IGY World Data Centers. These agreements call for the ultimate possession by each of three world data centers of all IGY data. The three world data centers which have been established are located as follows: World data center A in the United States, world data center B in the U. S. S. R., and world data center C in Western Europe with branches in Australia and Japan. These data centers will not only acquire and hold the complete sets of all IGY data but will also make their facilities available to scholars and will provide copies of all data, at cost, to investigators at their request.

The flow of data to the centers is proceeding satisfactorily. The procedures vary from field to field, depending upon the problems unique to a given area. The procedures and time schedules are presented in the guide referred to above. The international cooperation which has characterized the observational aspects of the IGY is also present in the data interchange program, and data are flowing from all parts of the world. There are also under way plans for the publication of IGY processed data; such publication will make the IGY data even more readily accessible to scholars everywhere.

In view of the specific interest in the satellite area of the House committee before which you testified, the following comments may be of interest. I have pointed out that the arrangements on data interchange vary from field to field.

In the satellite area the agreements may be summarized as follows: First, each satellite launching authority must advise all investigators (using press, radio, and IGY media) of the successful launching of a satellite as promptly as possible but within 24 hours at the latest. Second, preliminary reports describing experiments and instruments are to be interchanged within several weeks after launchings. A brief descriptive report on the first two Soviet satellites has been distributed. We ourselves hope to release some preliminary reports on the first of our satellites (1958 Alpha) within the next week or so. Third, the final results of satellite experiments are to be interchanged within 12 months after an experiment has been conducted. This timetable was based in part on the problems of analyzing telemetered data and in part from experience with rocket experiments, where a similar liberal schedule is necessary. Neither launching authority has yet issued final results of satellite experiments; each has some months of working time yet available for completing the analyses and then issuing final results

I hope that the above information clarifies the question which the House committee addressed to you, and I shall be happy to respond further as necessary.

Yours very truly,

HUGH ODISHAW,
Executive Director.

2. Requested a calendar of Vanguard scheduling and how it has been met or altered. This material follows:

The original Vanguard launching target dates are shown in the second column of the accompanying table. The objective of that schedule and subsequent changes has always been and still is to maintain a working schedule designed to assure launching of a 20-inch scientifically instrumented satellite during the International Geophysical Year. The period of the IGY is July 1957 through December 1958. The scheduled dates of proposed firings have always depended on the progress in development of the Vanguard launching vehicle. Because of this factor the schedule is in two segments:

(*a*) A test vehicle series, numbered TV–0 through TV–5 The purpose of these launchings was to check the performance of the vehicle and systems during the development program. Originally 9 test vehicle flights were planned, including 3 backups to be used in case of an unsuccessful test. For instance, the December 6, 1957, test of TV–3, which did not result in a successful flight, was backed up by the TV–3 backup vehicle launching on February 5, 1958. Although this flight was only partially successful it was possible to proceed on to TV–4, which placed a small test satellite in orbit on March 17, 1958. Thus TV–5 could follow TV–4. The TV–4 backup vehicle, no longer needed in the test series, is being converted into a full-scale IGY satellite launching vehicle.

(*b*) The second phase of the schedule consists of a satellite launching vehicle series, initially consisting of 7 vehicles numbered SLV–1 through SLV–6, but now increased to 7 by the additional of the converted TV–4 backup vehicle. Each of these vehicles is intended to launch an IGY scientific satellite. Originally, it was hoped that the test vehicle part of the program would be completed in time to permit the launching of SLV–1 in late 1957. Currently this first IGY satellite launching is scheduled for the spring of 1958.

The table shows the original working schedule and subsequent changes The changes have been carefully designed to take advantage of successes and information gained in the developmental and test program as well as to accommodate the time required to solve problems. For example, see footnote 3 of the table. The future launchings are planned at the rate of roughly 1 every 4 or 5 weeks; the exact dates are classified information.

Comparison of Vanguard vehicle tentative launch schedules

Vehicles	Date of working schedule for launchings					Actual launch
	November 1955 launch	March 1956 launch [1]	February 1957 launch [2]	October 1957 launch [3]	December 1957 launch [4]	
TV-0	Sept. 27, 1956					Dec. 8, 1956.
TV-1	Nov. 29, 1956	Jan 29, 1957	Apr. 25, 1957			May 1, 1957.
TV-2	Jan 31, 1957	Mar 8, 1957	July 26, 1957			Oct. 23, 1957
TV-2BU	Backup	Apr 19, 1957	Sept 6, 1957	Backup		NS.
TV-3	Mar 29, 1957	May 24, 1957	Oct. 15, 1957	Dec. 4, 1957 [5]		Dec. 6, 1957.[5]
TV-3BU	Backup	June 21, 1957	Backup	Jan 8, 1958 [5]	Jan. 18, 1958 [5]	Feb. 5, 1958.[5]
TV-4	May 30, 1957	July 26, 1957	Dec. 16, 1957 [5]	Feb. 12, 1958 [5]	Feb. 10, 1958 [5]	Mar. 17, 1958.[5]
TV-4BU	Backup	Aug. 23, 1957	Backup [5]	NS [5]	Nov. 19, 1958	
TV-5	Aug. 1, 1957 [5]	Sept. 20, 1957 [5]	Feb 14, 1958 [5]	Mar 19, 1958 [5]	Mar. 4, 1958 [5]	Apr. 28, 1958.[5]
SLV-1	October 1957 [5]	Oct. 31, 1957 [5]	Mar 21, 1958 [5]	Apr. 23, 1958 [5]	Mar 24, 1958 [5]	([6]).
SLV-2	December 1957 [5]	Dec. 6, 1957 [5]	Apr. 25, 1958 [5]	May 28, 1958 [5]	Apr 28, 1958 [5]	([6]).
SLV-3	February 1958 [5]	Jan. 14, 1958 [5]	May 30, 1958 [5]	July 2, 1958 [5]	May 26, 1958 [5]	([6]).
SLV-4	April 1958 [5]	Mar. 28, 1958 [5]	July 3, 1958 [5]	Aug 6, 1958 [5]	June 23, 1958 [5]	([6]).

SLV-6	August 1958 [5]	Aug 1, 1958 [5]	Sept 12, 1958 [5]	Oct 15, 1958 [5]	Aug 18, 1958 [5]	([6]).

[1] Both the General Electric Co. (1st-stage engine) and the Aerojet-General Corp. (2d-stage engine and tankage) had determined that more time than that reflected in the November 1955 schedule would be required to meet the specifications on weight and performance

[2] During the late fall and winter of 1956–57 the Martin vehicle development program ran into difficulties (*a*) 1st-stage engine (GE) Scoring and burnouts, performance below specifications, and injector redesign (*b*) 2d-stage engine and tankage (Aerojet) Injector redesign, vehicle design changes that affected 2d-stage design, many rejects because of difficult component fabrication, and tank fabrication problems required new approaches (*c*) The 3d stage. Overweight and required additional development to meet weight and performance specifications (*d*) Structural· It was suspected that the structural design of the vehicle was inadequate to withstand the vibration loads. Design and production was stopped until the problem was resolved

[3] The successful firing of TV-1, which showed that the 3d-stage design was adequate, made it possible to revise the test program to include test satellite firings starting with TV-3. This is appreciably earlier in the program than had been thought possible before. The revisions to the test vehicles to accommodate these changes produced the delay shown

[4] The ability of the Martin Co. to increase the delivery of the vehicles and the provision of additional personnel at AFMTC permitted a schedule revision It was decided that the static firing of the 2d-stage engine at AFMTC accomplished no major useful purpose, thus this and several minor tests were eliminated, which, coupled with the other improvements outlined above, resulted in this schedule revision.

[5] Vehicles having satellite launch capabilities.

[6] Remaining vehicles planned 1 each 4 or 5 weeks; schedule planned to be completed by December 1958

3. Requested a calendar for the proposed advanced Vanguard program and an estimate of costs for this program. This material follows.

Brief of proposed Vanguard Post—IGY space research program (unclassified portion only) (U. S. Naval Research Laboratory, Washington, D. C.—Project Vanguard)

1. *Program description.*—Project Vanguard is the name applied to the Department of Defense satellite project designed to establish at least one scientifically instrumented spherical satellite in a sustained orbit around the earth before the end of the International Geophysical Year (IGY) (December 31, 1958). Technical management of the program is the responsibility of Project Vanguard established at the United States Naval Research Laboratory to perform this mission. This initial mission will have been completed and most or all of the available vehicles launched around the end of 1958. Because of the long lead-time required for procurement and especially the time required to plan a logical, sensible, and scientifically worthwhile space project, Project Vanguard has requested immediate authority and funds to initiate a program utilizing the in-being management and technical competence of Vanguard, built up since the fall 1955. The essential features of this program are:

(*a*) To develop satellite systems with up to 50 pounds payloads using improved Vanguard launching rockets as carriers. These rockets can be made available starting before the end of the calendar 1958 provided immediate go-ahead is authorized. The improved Vanguard is simply the current Vanguard with an improved third stage which is under development.

(*b*) To employ existing Vanguard personnel and facilities plus other diversified naval research laboratory capabilities to provide program management, scientific and operational instrumentation, satellite tracking, vehicle, orbit and scientific data analysis, and including research and development.

(*c*) To make optimum use of Vanguard capabilities by replacing the first stage booster in the Vanguard vehicles with more powerful first-stage boosters. As earth-satellite carriers these vehicles would provide payload capacities of several hundred pounds dependent on inclination and direction of launch with respect to the earth's equator and rotation. These model III Vanguards could also serve as lunar research vehicles. It is to be noted that the unique Vanguard launch facilities at Cape Canaveral provide the guidance capabilities required for lunar flights.

2. *Program functions.*—The proposed Vanguard post-IGY program is a complete functional program containing all of the elements necessary for a complete program of space research. It is especially attractive since the project is the only one in existence which has all of the combined capabilities required under one roof and a single project director. These functions include:

(*a*) *Radio tracking.*—Maintenance, operation, research and development and increased capability of the Vanguard tracking network.

(*b*) *Telemetering.*—of data on vehicle performance in addition to the prime function of telemetering scientific and/or operational data from the satellites.

(*c*) *Satellite instrumentation.*—The early satellites accrue certain obvious political impacts just by maintaining an orbit, being of a certain size or other features which will diminish in value as they become more common Then, their real value will be more rationally assessed in terms of their scientific worth. This program includes the necessary scientific skills to conduct a program to develop instrumentation of a sophisticated nature. The Naval Research Laboratory's 12 years of experience in high altitude upper atmosphere instrumented rocket research provided the know-how for Vanguard. In this area, Vanguard seems to be temporarily ahead of the country's closest competitor. Only an adequate program now, will maintain this position.

(*d*) *Payload packaging and development.*—Current satellite internal and external configurations are not the final answer. This function must be performed in conjunction with instrumentation development and in consonance with vehicle design and performance characteristics. The package is a part of the vehicle structurally and in other respects. The program includes the scientific engineering effort required for further development in this area.

(*e*) *Theory, data processing and analysis.*—This includes all aspects of the data function from theory through analysis of data on trajectories, orbits, design requirements, range safety, ad infinitum.

(*f*) *Vehicles and launching.*—The manufacture of vehicles and physical launching effort is of course, contracted for. The Vanguard vehicle development was based on previous experience of the NRL vehicle staff in developing

very high performance rocket research vehicles such as Viking. The proposed program includes development effort on the improved and advanced Vanguards.

(*g*) *Other functions* such as some communications, logistics, range use and support are performed by the three military departments' facilities as available. It is assumed that these and additional Government facilities will continue to be used and available for space-research purposes. Roughly 85 percent of Vanguard dollars are spent at private contractor facilities.

3. *Program schedule.*—The fixed points in time at which various phases of the program can be completed depend on the date the go-ahead is given and sufficient funds made available. The Vanguard-IGY program has now progressed to the point where each day's delay in authorization of a post-IGY-Vanguard program is translated into additional delay of the advanced program (this condition has existed since January 1, 1958). Delay in go-ahead also increases costs because production lines, facilities, and especially management and research teams are expensive to reassemble once they have been closed down or atrophied.

If the go-ahead were given by June 1, 1958, the first firing of the improved Vanguard (50-pound satellite) would be in early spring 1959, almost immediately after the end of the current IGY series of launchings. The advanced Vanguard (larger satellite and space research craft) series would begin in about 2 years. This assumes a very high priority on procurement and use of facilities.

4. *Program cost.*—To conduct a complete program encompassing advanced work, operations, and research and development would require a level of about $50 million a year for the next 3 years (fiscal years 1959, 1960, and 1961). The costs beyond that point would depend of course, on accomplishments, progress, and program objectives which cannot be determined precisely enough for cost estimating now. It is suggested that an annual basic level of $50 million would guarantee a very sophisticated and advanced program.

4. Requested a comparison between the Russian programs and our own programs and our own programs on earth satellites. This material follows.

We have never been told in explicit terms what the Russian program for earth satellites is comprised of. It is known, however, that the Russian program aims in rockets and satellites are similar to our own in that they are mainly directed toward the measurement of geophysical quantities and of the solar and cosmic radiation high in our atmosphere. To date the Russians have had two successful launchings. Their first satellite apparently was mainly a test satellite; the second measured solar and cosmic radiation and in addition carried a live dog as an experiment in space medicine.

The Russian satellites and launching vehicles have been larger and heavier than any of the three we have launched.

5. Requested a glossary or dictionary of scientific terms coming into official use. I am informed that the clerk of the committee is attending to the acquisition of such a glossary, and that it need not be submitted by me.

6. Requested my own definitions for scientific or technical terms used in my testimony. This material follows:

Glossary of Technical Terms Used by Dr. Hagen in His Testimony

1. Acceleration—any change in the magnitude or direction of the velocity of an object. Linear acceleration may be thought of as the rate of change of the object's speed. For example, an acceleration of 2 feet per second means that an object's velocity is increased by 2 feet per second during each second of time that elapses.

2. Backup—an alternative, a provision against delay or failure of a planned device or objective, a replacement or substitute.

3. Decay—as applied to orbits, the loss of energy by the satellite resulting in shrinkage of the orbit.

4. Drag—the retarding force exerted upon the satellite or rocket by atmospheric friction.

5. Mass—that property of matter which exhibits inertia, or resistance to change, in motion, and has weight when in a gravitational field. The net force exerted on an object, divided by the resulting acceleration.

6. Orbit—the path of an object which revolves about a larger or primary object under the influence of a gravitational field.

7. Payload—the useful weight carried by a rocket vehicle, the weight associated with the actual performance of the final objective as distinguishd from

the weight of the rocket's system itself. Example: Vanguard has in orbit some 55 pounds. Only the 3½ pound weight of the satellite sphere itself constitutes a payload.

8. Period—the time rquired for one complete circuit of the earth by an orbiting satellite.

9. Perturbation—any deviation in the orbit of a satellite due to a disturbing force.

10. Propellent—any of the substances whose chemical combination or burning produces the thrust of a rocket. Propellents of a given rocket stage consists of a fuel and an oxidizer. Depending on the particular rocket, both propellents may be either liquid or solid and may be stored separately or as a mixture.

11. Reentry—the descent into the earth's atmosphere of an object launched into space.

12. Satellite—any object in an orbit about a larger primary body.

13. Solar cell—a photosensitive device for converting sunlight into electric power.

14. Specific impulse—the magnitude of the thrust derived from burning propellents at a given rate.

15. Stage—a rocket which together with other rockets makes up a composite vehicle. A given stage is separated from the remainder of the vehicle after it has fulfilled its function.

16. Thrust—the propelling force imparted to a rocket by the exhaust from its engine.

17. Trajectory—the path of an object fired or projected from one point toward another point. A trajectory is distinguished from an orbit by its finite length.

18. Vehicle—an object or device designed to transport another object or device. A satellite launching vehicle is a device to lift a satellite payload above the sensible atmosphere and discharge it into an orbital path at a given speed.

19. Velocity—the rate and direction of a moving object. Loosely, the speed of the object

20. Weightlessness—the absence of any net gravitational force upon an object relative to its immediate surroundings. An object or creature inside an orbiting satellite, for example, will experience no weight.

Mr. Brooks. I notice particularly the indefiniteness on some of the points that have been made here this morning, when the comment had been made by Mr. Sisk to project a payload, object, or otherwise. You can't tell what that means.

Nor can you tell what you mean when you said "All these satellites going through the air." You didn't mean air, you meant atmosphere.

Dr. Hagen. Yes, sir.

Mr. Brooks. Or space.

If the gentlemen would yield, before any more members of the committee get away, and we have lost some already so they will have to be notified, the chairman asked that the committee meet again this afternoon. The time of the meeting this afternoon would be dependent on the time we recess at noon.

What is the pleasure of the committee?

It is my thought, and it is noon now, that if we adjourn now or within the next few minutes, we can meet at 2. But if we go over until 12:30 or a quarter to 1, and either one would be all right with the Chair, that then we would meet at 2:30. What is the pleasure of the committee?

Mr. Fulton. Could we suggest meeting at 2, and then if you would appoint a substitute chairman if you have to go to the floor——

Mr. Brooks. I will stay here as long as the gentleman wants to stay. If he wants to go straight through to 2 o'clock, in order for him to have the opportunity, I will sit with him and go without lunch or have sandwiches sent here, either one.

Mr. Fulton. I will only take about 5 or 10 minutes more.

Mr. Brooks. Very well.

Mr. Fulton. For example, the use of the words "vehicle," "missile," "rocket," I would like specifically explained in your glossaries, as well as what are meant by "manned or unmanned guided vehicles," "missiles in space," and whether they are powered either internally or externally.

We need some sort of a definition that we could come up with, some language that is going to be mutually accepted among the scientists and the legislators. We are each talking our own kind of a jargon.

How much money would it take you, and in what period of time would you need it, to put full speed ahead on the advanced Vanguard program?

Dr. Hagen. I think to complete the first step in the advanced Vanguard program, and to obtain a sufficient number of vehicles to do useful work, the total national cost of this would be something on the order of $50 million.

Mr. Fulton. How much?

Dr. Hagen. $50 million.

Mr. Fulton. And within what period of time? How soon would you need it? And give us the order of magnitude of the partial payments to you.

Dr. Hagen. Approximately half of this would be needed upon determination to go forward with the program, and the remainder would be required before the end of the next fiscal year.

The vehicle launching part of the program could be handled within 1 or 2 fiscal years depending upon the desires of the Department.

Mr. Fulton. There was a dispatch from Reuters yesterday, saying that the United States Government was going to make a shot to the moon on Wednesday of this week.

From your own information, and from that of your Department, can you deny that you are going to make such a shot?

Dr. Hagen. I can testify, sir, that I am not going to make such a shot.

Mr. Fulton. And nobody, to your knowledge?

Dr. Hagen. To my knowledge, nobody.

Mr. Fulton. All right, that lays another rumor aside. The Air Force is now in charge of the rocket shot to the moon, and your project is contributing by the use of certain Vanguard equipment, which we will not go into. Is that the best setup for the shot to the moon, to get it done quickly, or should there be more authority given to the Vanguard project on equal participation?

Dr. Hagen. Well, I believe that in block diagram this is a proper approach, but that the net effectiveness of the approach could be improved if more of the Vanguard techniques as well as hardware were used.

Mr. Fulton. But, as a matter of fact, when it is done on that basis, through the Air Force, using some of your hardware and equipment, isn't that robbing Peter to pay Paul? You would be having other scientific programs going ahead on the Vanguard project if you were not deprived of the materials to go over to the moon shot under the Air Force.

Dr. Hagen. Whether it would rob Peter to pay Paul would depend somewhat upon the arrangements made for the method of doing the

job. The acquisition of the hardware for this job by the Air Force, for example, would not necessarily penalize the Vanguard program.

Mr. FULTON. The inference of my remark is: Should we not prepare to have further funds given so that the Vanguard program is not penalized through part of its hardware being taken away for a specific lunar shot?

Dr. HAGEN. Yes, sir. I think my answer to that would be "yes."

Mr. BROOKS. Will the gentleman yield?

Do I understand the doctor to say that the moon shot is retarding the Vanguard program?

Dr. HAGEN. No, sir, I don't believe I said that. I said that the acquisition of the hardware, Vanguard hardware, by another service, by the Air Force, does not interfere with the Vanguard.

Mr. FULTON. But if you had further funds to go ahead with other hardware, it would facilitate your program rather than looking at the other side of it, that it is penalizing it to take this other step?

Dr. HAGEN. That is correct.

Mr. FULTON. Might I say further that I am surprised that you have dismissed so completely the possibility of meteorite contact with the satellite in your 200-year projection for its life.

How high is your apogee on that?

Dr. HAGEN. 2,463 miles.

Mr. FULTON. So for a space of 2,463 miles as a radius, you are then really saying there is very little danger of satellite collision with meteorites in a 200-year period?

Dr. HAGEN. Destructive collision. Within that period there will certainly be collisions with meteors. But, as you know, most of these meteors, even those you see as so-called shooting stars, are very tiny things. The probability is high that there will be collisions of things like this with the satellite; however, the chance of their doing much harm is not great. They can puncture the thing and go through it, and unless they happen to hit the small transistor or the oscillator, or one of the wires, they can do no damage. They can do some damage by gradually eroding away the surface of the satellite, and eroding away the solar cells. But the rate at which that erosion will take place we are now determining in the IGY program. I don't believe that it will be so high as to endanger the life of this satellite.

Mr. FULTON. On your own statement, then, as it erodes, those pieces travel right along with it, so it will really turn into just being a cloud of little vehicles, finally, and still going around, will it not?

Dr. HAGEN. Yes, but, since these vehicles will now be separate entities, the drag effect on them, because they have separated from the larger mass, will be different, and they will be spread out along the orbit.

Mr. FULTON. In answering Congressman McDonough, of California, you said the firing from missile to missile, or satellite to satellite in outer space might be like between ships. I am sure that on a military premise, you do not mean that the explosions would take place there so that you could destroy a satellite in the same way, as there is no air. If we have an explosion in outer space, then it simply means giving various minute particles either a different orbit, arc, or straight line thrust.

Dr. HAGEN. The parallel I meant to make was in the problem of the trajectories. As far as the ability to destroy is concerned, it would

be more akin to the use of shrapnel, that one could or would explode a warhead in space, and when he does so, pieces are going to fly away.

Mr. FULTON. Yes, but then you would have a tremendous number of so-called vehicles or pellets moving around up there.

It would be like running through a gravel storm.

Dr. HAGEN. Yes, sir, that is correct.

Mr. FULTON. Now let us look at your 200 years, too. To see what the limits we on this committee should set for our outer space, the taxpayers require us to keep within certain bounds. For example, on the 200 years, there are 31,536,000 seconds in a year. So at 5 miles a second for 200 years, multiply our 31,536,000 by another 1,000, gives us 31,536,000,000 miles the satellite is going in 200 years.

If it is going 31½ billion miles, it will go around the earth in—let's see how that would work out. At 5 miles a second, it is going around the earth about 16.28 times a day. So in 200 years it is going to go around the earth about 118 million times.

Isn't that a tremendous use of energy?

Dr. HAGEN. Well, due to the fact that out in this region there is so little atmosphere left, therefore so little friction, then the energy we put into this satellite is going to be very effectively used.

On the plane last night, I did some arithmetic similar to yours. I don't know whether my answer is exactly the same, but it is in the same——

Mr. FULTON. I did it while I was sitting here.

Dr. HAGEN. Period. The total distance, if the Vanguard satellite stays up 200 years, the total distance is going to be on the order of 26,000 million miles.

Mr. FULTON. I have thirty-one thousand five hundred—thirty-six thousand million miles. (EDITOR'S NOTE: Verified as correct.)

Mr. KEATING. Split the difference.

Mr. BROOKS. I think that is fair.

Mr. FULTON. The question is this, in relation to outer space, though. We have to look at the problem probably on a planetary system, because of the speeds at which we are talking, 5 miles a second. If you took 1 light year, that would be 6 trillion miles, and if the nearest star is 26 trillion miles away, the distance our satellite, that you put up, will go in 200 years is inconsequential, being only 31½ billion miles.

Dr. HAGEN. It would take the Vanguard satellite, going at the speed it is presently going, about 200,000 years to get to Alpha Centauri, one of the closest stars. It would take it in round numbers approximately 10 years to get as far as the outskirts of our own solar system. The point that this brings up is that one of the problems that we have not in this country, as far as I know anywhere in the world, effectively attacked as yet—the matter of developing thrust devices which can go in these space vehicles and slowly build up their speeds far beyond the speeds with which we are now accustomed.

Once the vehicle gets far out into space, where the gravitational fields are weak, then the application of a very small thrust over a long period of time could bring the velocity up to many, many times the velocities that we are now talking about, and these ages and years can be reduced in number.

Mr. FULTON. May I say as a compliment that I have, prior to the Vanguard shots, worked down there at the Cape Canaveral as a Navy

officer on duty, not as a Congressman, and have been impressed with the efficiency and the dedication, and, likewise, acceptance of danger of the various scientists and technicians who have been working on the Vanguard and the other rocket and missile programs.

Don't you think it is necessary that we have some sort of a policymaking body, or that we in this resolution should come up with some method of setting the policy for our scientists? Obviously, there has been no overall policy, security policy, set for the Vanguard program. This is a new field of science. Why, then, don't we have another kind of a policymaking body that will make sure we are not giving away vital secrets if the Russians aren't being open? Wouldn't you agree that that should be set out?

Dr. HAGEN. Yes, sir. I believe that this is something that should receive the kind of detailed attention which it probably cannot receive today from the very high level groups which discuss this point.

I think this is the point you are driving at.

Mr. FULTON. I might say to you that I am accidentally a Congressman. I was elected without making a speech when I was in the Pacific in World War II. I was aiming to be a mathematics teacher at one time. I have gotten diverted a little bit. Let me ask you this: Why are scientists now making these treks to Russia so much?

I understand there is one New York City scientist associated with one of the institutions, who is making his second trip to be wined and dined.

Why is he so often going to Russia? Is there any need of that?

Dr. HAGEN. I don't know.

Mr. FULTON. Not why this individual, but what is the need of them all flocking over there now?

Dr. HAGEN. I think one point in need is that we can determine very, very little about the capabilities and the plans and the hopes of the Russian scientific community by what one reads in the journals and in the newspapers; that there is only one really effective way to evaluate their performance and to evaluate their intention, and that is to have an opportunity to visit them at home, and to see what their achievements are, and to have the ability to ask questions.

Mr. FULTON. How nearly before the successful launching of the first sputnik in point of time were the Russian scientists given full and free access to all of our facilities here and your plans in the United States?

Dr. HAGEN. It happened to be about the month preceding the launching of the sputnik.

Mr. FULTON. In August, was it?

Dr. HAGEN. Starting in late August and going through September.

Mr. FULTON. Around August 26?

Dr. HAGEN. Yes.

Mr. FULTON. If that was done, it was very likely, then, that they got the latest of our developments, and the latest calendaring that we had so that not only could they see what we were going to do, but they could also calendar our operations to figure out in what length of time, competitively, they would have to act first, couldn't they?

Dr. HAGEN. Yes, I think that is probably true, they had more of an opportunity to do that than we certainly had.

Mr. FULTON. So, really, they not only had the benefit of the eagle's back, so that they, like the canary, could jump the extra 3 feet, but they

could find when the eagle was going to do it, and then they could take the jump first.

Dr. HAGEN. This is due to the method of operation. This is undoubtedly true. They had this advantage over us.

Mr. BROOKS. Will the gentleman yield again?

Mr. FULTON. Yes.

Mr. BROOKS. We actually announced the exact date that we expected to launch the satellite.

Dr. HAGEN. That was at a later date.

Mr. BROOKS. It was?

Dr. HAGEN. Yes.

Mr. BROOKS. Did I understand you to say that they had full access to our facilities here?

Dr. HAGEN. I should qualify that. They had full access to certain parts of our facilities. I should make clear that at the time the satellite effort was announced by the White House and then by the Department of Defense, it was made clear that there were certain aspects of the Vanguard-rocket which would remain classified.

Mr. FULTON. As a missile program distinguished from a satellite vehicle program.

Dr. HAGEN. Yes. And the only commitment we made was that the satellite itself and all that was in it and all of the results that came out of it, would be freely exchanged.

Mr. BROOKS. I sponsored the program to set up that base. In fact, I introduced the bill that set up the base down there at Canaveral, in Florida. Do they have complete access to that facility?

Dr. HAGEN. No, sir. I don't think one of them has ever been on it.

Mr. BROOKS. That is the point I wanted to clear up.

Dr. HAGEN. Nor do they have complete access, for example, to a laboratory here in Washington. They have been allowed to visit certain restricted areas in the laboratories, where work on unclassified things has been done.

Mr. BROOKS. Or to Wright-Patterson? Have they had access to Wright-Patterson?

Dr. HAGEN. I can't answer that. I wouldn't know.

Mr. FULTON. Could we have your agency put in, then, the calendar of the Russian visits to your installations, and also who they were, what their qualifications were, and what access they had to various types of facilities and consultations.

(The material referred to is as follows:)

On October 7, 1957, a tour of the Vanguard facilities at NRL was conducted for members of a conference on rockets and satellites held at the National Academy of Sciences in Washington This was a conference held by the Comite Special de l'Annee Geophysique Internationale. Among the visitors were three Russian scientists: Lt. Gen. Anatoly A. Blagonravov of the Soviet Army, a ballistics expert and member of the Soviet Academy of Sciences; Dr. Sergei M. Poloskov, a physicist associated with rocket and satellite experiments; and Mr. A. M. Kasatskin, associated with rocket and satellite instrumentation.

The visitors were shown research instrumentation used in the Aerobee rocket program for the IGY; they were addressed on the subject of cryogenic research by Dr. Henry of the solid state division; they were shown some shock and vibration test equipment associated with our satellite testing in the mechanics division; they were conducted through the shops where Vanguard satellites and scientific instrumentation were being assembled; and they visited the Vanguard control center, where they viewed the communications room through a window but did not enter.

The IGY is concerned only with scientific experiments, with earth satellites and orbits, and not with the rocketry per se or with military devices. This policy was adhered to in the tour, which was on a completely unclassified basis.

Mr. FULTON. You had said there was a tremendous urgency about the space program. Do you believe that it should be implemented immediately?

Dr. HAGEN. Yes, sir, I think it should. Because of the long lead times involved here, which I referred to before, if we hope to stay with this field we should no the planning that I feel needs to be done, we should do that immediately, and we should then get on with the job.

Mr. FULTON. Do you favor the immediate starting of a project for a third of a million pound thrust engine?

Dr. HAGEN. On general principles, I believe we should proceed with the development of an engine of much higher thrust.

Mr. FULTON. Would you favor also the million pound thrust?

Dr. HAGEN. This is what I was leading to. I believe we should go for an order of magnitude improvement in thrust. I think we could do that safely even before the planning procedure has been gone through, because it is clear that if we are to do anything much beyond what we presently are capable of doing, we must have a higher thrust engine.

Mr. FULTON. I believe the Defense Department has allocated $500,-000 on an annual basis so far on study funds for the million pound thrust engine, or the engine of a greatly increased magnitude. Is that right?

Dr. HAGEN. I have not been exposed to the details of this item.

Mr. FULTON. I can say to you that is about the amount. How long do you think it will take to develop a million pound thrust engine?

Dr. HAGEN. If all went well, I think we would be very fortunate to have an operating engine in anything less than 2 or 3 years. It would take a long time.

Mr. FULTON. And how many millions of dollars would it cost for the research and development of the million pound thrust engine?

Dr. HAGEN. Judging on the basis of my experience with the smaller engines, I would expect the cost of such a development to be greater than $100 million.

Mr. FULTON. So that at the rate of $500,000 annually on appropriations, it would take 200 years' worth of money in order to get the million pounds thrust engine going if we just keep on at the same rate of study?

Dr. HAGEN. I don't know how you arrive at that same——

Mr. FULTON. Well, a half millions dollars a year we let you have for study, and you say it is going to take $100 million.

Dr. HAGEN. I am sorry. I was struck with the similarity of that number to the lifetime figure we were using. I believe that this initial effort should be used to determine the feasibility of going ahead, and then, if it is proven to be feasible, certainly we are going to have to accelerate the rate at which we spend money.

Mr. FULTON. That brought up this point, and I was going to ask it, for you to give us a short calendar of amounts and timing. How soon would you need the first money? Maybe $15 million in the next fiscal year to start with, or $25 million? How much would be an adequate program for the original basic study on laying out the plans?

Dr. HAGEN. I don't believe I could give——

Mr. FULTON. Could you insert that into the record?

Dr. HAGEN. I could do that.

Mr. FULTON. I would like to get the planning, so that we can make a recommendation on the committee level as to what should be done.

(The document referred to follows:)

The development of a rocket engine with a thrust of 1 million pounds would require several years of research, development, and testing. The research and development would be principally in the area of high-energy fuels, heat transfer, and materials resistant to abrasion at high temperatures. In order to obtain a reliable motor in the shortest time, an intensive effort would be required in the first year of research and development. Funds to start such a project are difficult to estimate but should be at least $10 million for the initial year's effort, $40 million for the second year, and $50 million for the last year and first prototypes. A basic study to lay out plans would cost in the neighborhood of a few hundred thousand dollars.

Mr. FULTON. Do you favor a great advance in the research on these hypergolic fuels for the second-stage Vanguard, or would you move to something else? Would you emphasize the solid-fuel propellents? Where would you put the emphasis? We can't do it everyplace.

Dr. HAGEN. You understand when you ask that question that you get right into the middle of a strong argument between the propulsion people.

Mr. FULTON. Would you put a statement into the record?

Dr. HAGEN. For the long-range problem, I believe that we should put our greatest effort in chemical fuels in the solid-propellent engine for the purposes for which we are discussing this today.

Mr. FULTON. Then would you continue a program of research on the ion propellent?

Dr. HAGEN. Yes, sir; because that would be used for a different purpose. This is that low thrust, long-burning device which is needed for later use.

Mr. FULTON. And you really need that for guided power on outer-space vehicles, don't you?

Dr. HAGEN. Ion or its equivalent; yes, sir.

Mr. FULTON. Do you think there is any practical use in continuing with a research program for light propulsion?

Dr. HAGEN. I don't believe that I could give an answer to that, except to say that——

Mr. FULTON. Would you put it into the record later?

Dr. HAGEN. That it should be considered later.

Mr. FULTON. It should be?

Dr. HAGEN. Yes.

Mr. FULTON. There is enough there to have it considered on a study for the future, rather than to have a tremendous expansion of the proton program?

Dr. HAGEN. Only for study.

Mr. FULTON. Let me just finish with this point. When you bring up your theory of the planning of a national policy for the United States for outer space, you are talking philosophy, and that brings up the point as to how the United States should advance into outer space. From what you say, I would conclude that we should have a United States program that we effectively plan as a governmental project and as a governmental project administered. Is that right?

Dr. HAGEN. Yes, sir. That is exactly right.

Mr. FULTON. Secondly, that the Government itself should take the policy control and aiming of the direction of scientists largely employed by the Government in a space agency which is a Government agency; is that right?

Dr. HAGEN. In this one area, yes.

Mr. FULTON. You are really negating a very important field. You are saying that business should not do the planning, and the competitive United States system should not move into outer space other than under the policy control of the Government; isn't that right?

Dr. HAGEN. I believe it is the United States program, and the Government should plan what it is doing; yes.

Mr. FULTON. I think you have settled in your own mind that our United States national space policy should be on a broader base than simply a race in competition with Russia and her satellites?

Dr. HAGEN. Yes, sir.

Mr. FULTON. That puts you with a peculiar group. Historically speaking, for example, Grotius was the man who came up with the "freedom of the seas." Then along came a man named John Selden of England, in 1635, who came up with the policy for Britain of dominion of the seas. "Freedom of the seas" means that nobody has done anything about it much, and the satellites are up there. I think Congressman McDonough, of California, was a pretty good exponent of that position, and it is a rather laissez faire position—let it just ride along until something happens, until there is a collision, or let anybody do anything they want, there is no law about it, and then see what happens.

However, John Selden said that you must have the power to control, the power to dominate, although you don't actually try to dominate all the space, as Britain certainly couldn't dominate the seaways of the world. General Putt, in his testimony, clearly outlined the military approach, which is, "We must have the power to control by military means whatever outer space is near the earth and likely to have any effect on our security." Your position, though, is one that I favor when you say, "We should have an international conference." Is that right?

Dr. HAGEN. That is correct; yes.

Mr. FULTON. The second thing—an international conference would have to be called by the President. So, I have recommended previously that this committee make a policy recommendation to the President to take this question of an outer-space international conference up at the summit. Would you go along with that?

Dr. HAGEN. Yes, sir.

Mr. FULTON. That brings us to this point: We tried to cut across this freedom-of-the-seas policy, and, also, to cut across the policy of dominion of the seas, in 1899, when we were one of the major powers. There was an international conference called of nations to see if we couldn't come up with some sort of a permanent peace body. As you know, the International Court at The Hague resulted from it. Then, rather peculiarly, in 1907, there was a second Hague Conference called at the invitation of Russia, and the United States accepted. So, there is a previous historic precedent for the calling of an international conference. It was actually called by Russia. The question that we would have on this, my question, would be, and I would say it, too,

you would then not favor putting this space problem and space policy of the United States under the United Nations, either in the General Assembly, where there is no veto, or in the Security Council, where we would run into big power and veto problems, would you?

Dr. HAGEN. I am afraid that I don't know enough about the operation of the United Nations and the feasibility of using it in this way to know whether this is something that should be recommended. It doesn't appear that it should be.

Mr. FULTON. But the trouble with the United Nations is that all the nations of the world and some of the big powers are not now in it. Red China is not now in it. So, your recommendation for an international conference is, actually, a conference for every nation of the world, isn't it?

Dr. HAGEN. Yes, sir; that is right. It would have to be.

Mr. FULTON. "I believe it would have to be"; is that what you said?

Dr. HAGEN. Yes.

Mr. FULTON. So, your recommendation is that we have an international conference of all the nations of the world to take up the problems of the peaceful use of outer space, and, likewise, to set up some sort of a judicial system that might be agreed upon by multilateral treaties?

Dr. HAGEN. That is correct.

Mr. FULTON. Thank you. You have been very clear.

Mr. BROOKS. Doctor, may I ask you this question, along the lines of those which have just been asked by my colleague, Mr. Fulton? Russia was a party to this international geophysical agreement. Was that a treaty or was that an agreement?

Mr. FULTON. No, sir; I believe this was simply an agreement.

Mr. BROOKS. Was it a formal agreement?

Dr. HAGEN. It was a formal agreement on the part of two international scientific groups, each of which represents its country in either an official or a quasi-official manner. This country was represented by the National Academy of Sciences.

Mr. BROOKS. The point I am getting at is this: Russia being a party to that, you, from what you have said, feel that Russia has violated its agreement.

Dr. HAGEN. I feel that the Russians may not have violated the letter of the law in the agreement, but what the Russians did not do was to present their plan as openly and as freely as we did.

Mr. BROOKS. In other words, they violated the spirit of the agreement rather than the letter?

Dr. HAGEN. Yes.

Mr. BROOKS. It is now 12:40, gentlemen. If there is no objection, the committee will stand in recess until 2:30. You can be back, can you, Doctor?

Dr. HAGEN. Yes, sir.

Mr. BROOKS. If there is no objection, the committee stands in recess until 2:30.

(Whereupon, at 12:40 a recess was taken until 2:30 p. m. of the same day.)

AFTERNOON SESSION

The committee reconvened at 2:30 p. m., upon the expiration of the recess.

The CHAIRMAN. The committee will be in order.

Mr. FULTON.

STATEMENT OF DR. JOHN P. HAGEN, DIRECTOR OF THE VANGUARD PROJECT, NAVAL RESEARCH LABORATORY—Resumed

Mr. FULTON. Do you believe the proposed nuclear tests to take place in the Pacific within the next few months are necessary and vital to our United States security?

Dr. HAGEN. The matter of the nuclear tests is somewhat outside of my present experience in Vanguard. However, there are certain aspects of these tests that I believe are essential to our national security.

Mr. FULTON. And in your judgment, then, anything that advances nuclear theory, advances both the peacetime as well as the warlike purposes and, therefore, it will bring us that much nearer to nuclear propellants for outer space vehicles, will it not?

Dr. HAGEN. Yes, work in the nuclear area is bound to contribute in the long run to nuclear propellants and nuclear propellants are something that we sorely need in the rocket field.

Mr. FULTON. In your firm judgment as a scientist, you would agree with President Eisenhower that the nuclear tests in the Pacific should be proceeded with even over Russia's objection and the objection of the British Labor Party?

Dr. HAGEN. Within the limits of my experience, yes.

Mr. FULTON. We have in the air now on behalf of the United States a security force. In your judgment as a scientist, are the B-52 bombers that we have in the air necessary parts of our strategic defense because of the fact that the missile and the satellite programs are not far enough advanced from their infancy yet?

Dr. HAGEN. I think that is certainly correct; that we must be in a position to defend ourselves with whatever we have at hand until we reach the ideal.

Mr. FULTON. So that the programs of space that we are working on do not mean and should not mean the cutting of our present security measures by the Armed Forces nor by the Air Force?

Dr. HAGEN. Certainly not.

Mr. FULTON. You would, therefore, have this program in addition to any other military programs for the protection of the country?

Dr. HAGEN. I think that is correct. In time all things change and the time may come when we will put more emphasis on missiles and satellites and the like and less on conventional aircraft, but that time is not here.

Mr. FULTON. Admiral Rickover said when he was before the committee last Friday that if he had been under the Atomic Energy Commission rather than under the supervision of the Navy, he could have gotten the nuclear submarine going "a damn sight faster."

Do you have any comments on the Navy's supervision of your project or do you disagree with Admiral Rickover?

Dr. HAGEN. I do not disagree with Admiral Rickover. In terms of the project that I have carried on, however, I would not direct the criticism specifically at the Navy. I would say that had we wanted to bring this project to fruition at the very earliest date, then the overall method of approach should have been different in the beginning and the lines of communication about the project should have been shortened. There should have been fewer committees and executives to whom you refer.

Mr. FULTON. How many echelons or layers of authority do you have to go through before you could get a firm decision on major policy matters in your agency?

Dr. HAGEN. On the very major ones, about five.

Mr. FULTON. Various levels of decision?

Dr. HAGEN. Yes.

Mr. FULTON. At this point in the record, with the chairman's permission, I would like a chart of the various authorities for decisions on the Vanguard program put into the record.

The CHAIRMAN. Without objection, it is so ordered.

Is it available?

Mr. FULTON. I think you can make them up showing where you went for decisions and how they were made and give us a history of it, if you will, at the various stages.

(The material referred to follows:)

PROJECT VANGUARD

LEVELS OF MANAGEMENT DECISION MAKING AND REVIEW

The following chart illustrates examples of major management decisions or decision areas in the column on the left The several levels to which proposed decisions must be referred for approval are shown to the right. Within the United States Naval Research Laboratory two approval levels exist, (1) the NRL Director of Research, who manages the entire Naval Research Laboratory research program (a civilian scientist) and, (2) the Director of the Laboratory (a Navy captain) who is of course responsible for the overall Laboratory program and operation. The Vanguard effort uses an average of one-tenth of total Laboratory effort in terms of manpower.

There are two levels of review in the Navy Department. The Chief of Naval Research is assigned overall management responsibility for Project Vanguard by the Secretary of Defense through the Secretary of the Navy.

The Office of the Secretary of Defense exercises two major functions in the direction of the program One is the review of the technical program which includes approval of requests for required facilities, use of other military service facilities, and approval or denial of insurance or backup efforts in the project. The second function is review of program budget including direction of the funding process and release of available funds.

The USNC-IGY is the United States National Committee for the International Geophysical Year, an instrumentation of the National Academy of Science, the latter being a quasi-Government agency set up by act of Congress to advise the President in scientific and related matters. The National Science Foundation is the Government agency which as one of its functions acts as executive agent for the National Academy of Sciences in the conduct of substantive programs such as the IGY. This administrative complex is concerned with the content of the scientific experiments in the Vanguard satellites (as well as the Army-IGY satellites) and coordinates the whole effort as an aspect of the International Geophysical Year. The only funds appropriated directly by the Congress for the USNC-International Geophysical Year satellite program prior to January 1958 was a supplemental 1956 appropriation to the National Science Foundation of about $27 million which included slightly less than $19 million for the Vanguard-IGY satellites. Roughly two-thirds of the latter amount was allocated to the Navy's Project Vanguard at the Naval Research Laboratory for satellite scientific

instrumentation and satellite tracking and data analysis. The other one-third finances the optical tracking program conducted by the Smithsonian Astrophysical Laboratory and for other Academy-Foundation program costs.

Mr. FULTON. Do you believe the speed of light is the absolute speed that can be reached, or are you one of the physicists that believe there is a variable speed and we would exceed it if we had one kind of energy we do not know about now?

Dr. HAGEN. No, sir. So far as I am concerned the speed of light does represent an absolute limiting speed to which we can bring matter, for example, the theory of relativity which now is well founded shows that the mass of a particle increases with the speed. This necessarily means it is not possible to accelerate that particle beyond the speed of light.

Mr. FULTON. When you get two galaxies that are moving apart, each at the speed of light, then to each other they are relatively moving twice as fast as the speed of light?

Dr. HAGEN. If they were moving apart at this rate, then they could not see each other.

Mr. FULTON. No; but relative to each other they are moving at a rate where the distance is increasing at twice the speed of light. So that if you take a fixed focal point, are you not right? But if you take a moving focal point you are not right?

If the speed of light is the way we see stars there could be stars that we do not even see because they are going away from us faster than the speed of light. We would never see them.

Dr. HAGEN. If it were possible that a star were receding at a greater velocity than the speed of light?

Mr. FULTON. Just at the speed of light.

Dr. HAGEN. Then we may never see them.

Mr. FULTON. Then the blank spaces in the heavens might be filled with stars also?

Dr. HAGEN. I don't think so. I think the theory shows that it is physically impossible for two objects to be moving away from each other at a speed greater than the speed of light.

This sounds contradictory to what was said earlier, but I believe the key to the explanation lies in the interpretation of time.

Mr. FULTON. Let me have one final question. It was given to me on a Navy examination here to see if I should be promoted from a Navy Reserve Lieutenant. I should like some authoritative advice: Thrust means, of course, the push forward; drag means to hold back; lift means the rise upward, force upward; and gravity means the pull downward.

What is a Vanguard rocket doing when the thrust equals the drag and when the lift equals the gravity?

Dr. HAGEN. If the thrust equals drag——

Mr. FULTON. And the lift equals gravity, what is the Vanguard rocket doing?

Dr. HAGEN. It is not doing very well; no, sir. If the thrust equaled drag there would be no net forward force.

Mr. FULTON. I am asking you. I made an answer that I thought this particular Vanguard was in constant, not accelerated forward flight, without power; it gets right to the stall point in the arc.

Do you know of a time when there is no thrust forward?

Dr. HAGEN. Only after the engines have ceased burning. The way the Vanguard is operated is that for the first, about 4 minutes, the first 2 engines burn, assert their thrust. The thrust is always greater than the weight of the vehicle.

Mr. FULTON. That is two g's. Now, suppose it just equals gravity at a certain point.

Dr. HAGEN. There would be an acceleration so long as there is any thrust at all, but the thing to remember is that by the time the thrust has fallen to the point where it is equal to gravity or less, the vehicle is near the end of its burning and it is at a high velocity.

Mr. FULTON. Will you insert that in the record when you are finished?

The CHAIRMAN. All the witnesses will be able to edit their testimony. You have permission to elaborate on that.

(Material is as follows:)

The acceleration of a rocket results from the net force acting on it. This net force is the difference between the forward thrust exerted by the engine, and the retarding forces of gravity and air drag. At takeoff, of course, and there is no drag, so the net lift or upward accelerating force is just the engine thrust, in Vanguard's case 27,000 pounds, minus the vehicle's weight, 22,000 pounds, or roughly 5,000 pounds. Thus the initial acceleration at takeoff is fairly low.

In flight, the air drag increases with speed until the rocket reaches high altitudes where the effect of the very thin atmosphere becomes negligible. The

weight of the rocket, however, decreases very rapidly as the propellents are used up. Since the drag is never very great and the engine thrust is nearly constant, this decrease in weight results in a higher and higher acceleration. Near the end of burning the rocket is virtually an empty shell and is under tremendous acceleration; of course there is still the deadweight of the remaining stages, but the acceleration is great enough to bring the entire vehicle up to a very high volicity in those last few seconds. At all times during the burning, the thrust of the rocket far exceeds the combined forces of weight and drag; if it were not so, the rocket would slow down instead of accelerating.

The process continues when the second stage take over. By this time the direction of flight is turning toward the horizontal. At the end of second-stage burning, the rocket has received enough upward momentum to coast the rest of the way up to orbital altitude in spite of the slight drag and the pull of gravity, just as a stone hurled upward will coast to a certain height.

At orbital height the third stage is fired, ideally in a perfectly horizontal direction In this case there is no upward force and the third-stage thrust is used entirely in giving the satellite a sufficient horizontal velocity to keep it in orbit; the spent second stage, of course, falls into the sea. The drag at this altitude is negligible so far as the third-stage rocket is concerned, even though it is sufficient over a long period to slow down the satellite.

To recap, then, the thrust of the rocket always greatly exceeds the drag and, even at takeoff, considerably exceeds the force of gravity. In the coasting period after the end of second-stage burning, there is no thrust so both gravity and the very slight drag of the residual atmosphere act to slow the rocket's motion. At all other times the rocket is under positive acceleration.

Mr. FULTON. Could I ask this request of the chairman? I have asked the various scientists who have appeared before us to give their definition of scientific terms and words they have used in their own testimony and in their statements.

Secondly, I would like a definition that is universally agreed on, adopted for this lingo that we are getting into so that the committee in its report can put out an authoritative definitive statement of some of these words.

Mr. FELDMAN. We are working on a glossary of terms.

Mr. McDONOUGH. This glossary of terms is already published in the last edition of Space Magazine.

Mr. FULTON. Just by the Air Force. I would like one that is a legal glossary for legislative use and adopt it as the overall terminology for both the legislative department, the executive as well as the services.

I should like an official glossary brought up by agreement of the scientists because in some places this morning even you were using the terms interchangeably, air, atmosphere and space.

The CHAIRMAN. Mr. Keating.

Mr. KEATING. Dr. Hagen, I know that I voice the sentiments of all members of this committee and all members of Congress in expressing our admiration for the devoted work that you have given in your field.

When Vanguard got up, we were delighted for many reasons, one of them being because of Dr. Hagen and the hard work he had put into it.

You know as well as I do that to many people in this country the previous attempts to get Vanguard up were looked upon as complete failures.

Now, that is not accurate, is it?

Dr. HAGEN. No; it is not accurate. They were test vehicles and the history of rocketry clearly demonstrates that one should anticipate a certain number of mishaps in any program. It was unfortunate that we had our mishaps at the very time we did have them. How-

ever, we did learn many things from these so-called failures that taught us to perfect a usable and successful vehicle.

I think this is a good opportunity for me to point out that even though today we now have a vehicle which demonstratively can put a satellite in an orbit, it would be very foolhardy for me to presume that all succeeding vehicles will be successful. We are bound to have other flights which do not put a satellite in orbit.

Mr. KEATING. Is there any doubt in your mind, Dr. Hagen, that the Russians have had many failures in getting a satellite into orbit?

Dr. HAGEN. There is no doubt in my mind at all. I would be hard put to prove that fact, but there is no doubt in my mind that that has gone on.

Mr. KEATING. That does not lend itself to capability of positive proof very easily, does it?

Dr. HAGEN. No; it does not. It requires the cooperation of the Russians in what they consider a sensitive area.

Mr. KEATING. It is not like atomic tests in that regard?

Dr. HAGEN. That is correct.

Mr. KEATING. But you are confident that there have been failures?

Dr. HAGEN. Yes.

Mr. KEATING. And are confident they have had as many as we have had?

Dr. HAGEN. At least as many.

Mr. KEATING. In that connection, you have spoken of 5 or 6 that you have launched to date.

Dr. HAGEN. We have launched six to date. Of these 6, the first 4 were test vehicles which were not complete vehicles and were not intended to have the full capability of putting a satellite in an orbit. These first four were uniformly successful. The next two vehicles we called failures. Those two did have the capability of launching satellites.

Mr. KEATING. Which were the ones that actually got in orbit?

Dr. HAGEN. No. Six. The sixth vehicle we launched. In other words, we have had four successes and two failures in our launchings. Of these 4 successes, 1 of them was so designed that it could put a satellite in an orbit.

Mr. KEATING. Now, your plan is eight more.

Dr. HAGEN. We have now eight more vehicles with which we will attempt to launch the IGY satellites; yes, sir.

The CHAIRMAN. Eight more vehicles? To do what?

Dr. HAGEN. To launch the IGY satellites.

The CHAIRMAN. Eight separate ones before the final launching of the big one?

Dr. HAGEN. No, I should clarify that.

There are five experiments to be done in the Vanguard program in the IGY. An X-ray, an ultraviolet, and a geomagnetic experiment, and two experiments on the weather. Those 5 experiments are assigned to 8 vehicles allowing us alternate vehicles in case of failure in 1 or 2 cases. In that 8-vehicle program, then we will attempt to put up 5 IGY experiments.

The CHAIRMAN. One in the very near future?

Dr. HAGEN. One in the very near future, and that one will measure X-ray radiation from the sun.

Mr. McDonough. If you had 5 successes in a row, get up your 5 different kinds of equipment, you might not go to your 8th?

Dr. Hagen. I think we would. If the impossible happened and we got the first 5 in a row, then we would scurry about and put up 3 more experiments for the IGY.

Mr. McDonough. Are those intended all to be done this year?

Dr. Hagen. Yes, sir; they are planned to go before the end of this calendar year.

Mr. McDonough. In that connection you made this statement this morning—and if I tread on the grounds of security you set me straight—that our chief competitor, and I assume you mean Russia, has a plan similar to our plan.

Are you at liberty to tell us what that plan is?

Dr. Hagen. I really am not at liberty to discuss that to any greater extent than I did earlier.

Mr. McDonough. That puts me in mind of this, which I have wanted to ask someone in authority on the matter of security. This time table of the services, except as they themselves release it, is considered a matter of security, is it not?

Dr. Hagen. Yes, sir. Our schedules are kept classified, but, of course, the point here is that in all of this missile work, eventually your laboratory becomes the proving ground and once you go to the proving ground it is virtually impossible to keep your everyday actions secret. They are open to inspection by the workers at the proving ground and by the press who can stay on the beaches and look up and see what is on the stand. So once the project gets to the point where you go to the proving ground to begin launching attempts, as soon as your missile is erected it is quickly deduced what your schedule is.

Mr. McDonough. The precise time of launching is not known, is it?

Dr. Hagen. No, sir it is not. It has always been our policy in Vanguard not to announce the precise time of launching until after the fact.

Mr. McDonough. Do I not understand that at Canaveral they have now made a gentleman's agreement with the press to tell them in advance of the date of launching under some honor system whereby they do not reveal it?

Dr. Hagen. This is my understanding. I have never been privy to the thing, but it is my understanding that such an agreement did at least exist a few months ago. Whether it is presently in existence, I cannot testify.

Mr. McDonough. I am asking some of these questions for personal guidance. I was down there and was given quite a little information about the plans. I would not have dreamed about saying anything about specific dates or anything of that kind.

I wondered whether I was being unduly cautious in that regard. That is a correct procedure to follow, is it not?

Dr. Hagen. Sir, if I knew the date of any firing down at Canaveral, I would do the same thing: I would be quiet about it.

Mr. McDonough. Now, I want to ask you this: You are taking readings from these scientific instruments which are in Vanguard and you were getting readings from sputnik that was up there. Have you gotten more and better reports from the United States satellites than you ever obtained from sputniks.

Dr. HAGEN. Yes, sir; we have, and for this reason: That we understand, know the experiment that is in each of the United States satellites and we therefore can derive a great deal more information from the results that are sent back.

This touches on a point that was raised earlier this morning that I probably should clarify just a bit, and that is this: The exchange of information that is planned as part of the International Geophysical Year does not encompass any exchange of classified information. That is, we have never revealed to the Russians information which we consider classified. In their visits here they have been exposed only to the unclassified portions of the work. We anticipate and expect that when the Russians get to the point where they have analyzed the data out of their two satellites that they will forward the information to the exchange mechanism and we then will be able to evaluate more properly just what they accomplished.

Mr. McDONOUGH. Is it your judgment that your equipment is superior to theirs in efficacy and that you are getting more and better information than they were able to get from theirs?

Dr. HAGEN. I like to believe that is true. I can state it only as a belief. At present we will have to wait until the end of IGY to make that evaluation.

Mr. McDONOUGH. But that is your belief at the present time?

Dr. HAGEN. It is my belief; yes, sir.

Mr. McDONOUGH. Now, when the Russians were here in late August in conference with you, you were involved in many of those conferences, yourself, were you not?

Dr. HAGEN. Yes, sir.

Mr. McDONOUGH. Did they say anything about the fact that the next month they were going to put sputnik up?

Dr. HAGEN. No, sir; they didn't, and even on the morning of the day that the first of them went up they just did not, in response to questions, answer as to when they might be ready to go.

Mr. McDONOUGH. They were still here that morning?

Dr. HAGEN. Yes, sir; they were still here, and in a meeting at the National Academy of Science Building on Constitution Avenue, they were asked this question. My remembrance of the answer was, well, they cannot say when they would go, but we would have plenty of time to change the frequencies in our radio observations, the point being that they did not use the agreed radio frequency for the beacon transmitter and we were quizzing them about that. It meant that we had to make wide changes in our stations. Their answer that morning was that we would have plenty of time to make this change.

Mr. McDONOUGH. You had agreed in setting up the plans for the Geophysical Year, you had agreed on the frequency that would be used?

Dr. HAGEN. 108 megacycles.

Mr. McDONOUGH. The Russians were party to that agreement?

Dr. HAGEN. Yes, and it was a year later at the Washington conference that they then told us thay did not intend to use 108, but they were going to use 20 and 40 megacycles.

Mr. McDONOUGH. How much ahead of putting sputnik up?

Dr. HAGEN. A few days. This was just prior to October the 4th when Sputnik I went up.

(EDITOR'S NOTE: The U. S. S. R. published in the June 1957 issue of Radio (in Russian) its intention to use 20 and 40 megacycles.)

Mr. McDonough. How can you deal with anybody that acts that way? What should we do in this situation?

Dr. Hagen. I think, at least I like to hope, that by playing the game very straight, by being careful about the information we divulge, we can, at least with their scientific people, build up a sufficient confidence so we can get an equitable exchange of information.

The Chairman. In other words, you do not think we should react to them?

Dr. Hagen. I think it would be too bad if we did.

The Chairman. You would take the affirmative side and make all disclosures possible consistent with the spirit of the IGY and consistent with our national interest?

Dr. Hagen. Yes, sir; I believe that is true.

The Chairman. I would feel unreservedly the same way. We cannot keep reacting. We have our side of the road and there are other nations and other scientists involved, and the most possible frankness has beneficial results.

Dr. Hagen. I think it does.

Mr. McDonough. Lest I be misunderstood, I agree with the statement of the chairman, but I know he would agree with me if you are sitting around a poker table and you are showing your cards you do not show your own unless the others show theirs.

The Chairman. When you get into poker, why——

Mr. McDonough. I would not imply that the chairman was ever in a poker game, but I am concerned as I am sure the chairman is, about the fact that we were somewhat misled.

Now, we should be very much on our guard not to let it happen again.

Dr. Hagen. Yes, and I believe you can be assured that necessary controls are there so that this cannot happen. All of the information is not going to be delivered in one fell swoop. It is going to be put down in bits and pieces and it soon will be clear whether we are in an even-Steven game or not. If we are not, then we should do something about it.

Mr. McDonough. Since they did not inform us of the frequency of the first satellite they put up, did they inform us of the frequency that they were going to use on the largest one they put up, the 1,100 pound one?

Dr. Hagen. I am not certain whether they did or not. It happened to be the same frequency so we detected it immediately. I am not sure whether we had information from them as to its frequency.

Mr. McDonough. Could we interpret anything from it, the electrical impulses we obtained from it?

Dr. Hagen. We learned a lot through observing that satellite. We at NRL observed it with radio and Dr. Whipple and his people observed it optically.

From these observations we were able to arrive at a new estimate of the density of the air at a height of about 130 miles. This was a very new and useful piece of information. How much of the remainder of the information that was radioed out of those satellites that may have been learned, I am not prepared to, or able to talk about.

Mr. Brooks. I merely want to ask this question: Since we now have three satellites up and Russia has none, do you notice any more interest on the part of the Soviets to reciprocate with information?

Dr. HAGEN. I have not detected it; no sir.

Mr. BROOKS. They have shown no change?

Thank you.

Mr. FULTON. Will the gentleman yield?

Mr. KEATING. Yes, I will yield again.

Mr. FULTON. In the sum total of exchange among scientists in the United States and Russia, how would you calculate whether we in the United States have gotten a fair return of information during these conferences? You must remember that the State Department, just about this time, is preventing a piano player and violin player from coming into the city of Pittsburgh to play because of security reasons, or let them go to Cleveland or New York.

Dr. HAGEN. I believe that if you wish to discuss this point in its full detail, you would have to consider the whole of the IGY and that should be referred to the National Academy.

Mr. FULTON. Will you put in the record a statement on that, please?

Dr. HAGEN. Yes.

(The material referred to is as follows:)

It is always wise to meet with scientists from other countries in conference. The planned exchange is that of information concerning scientific experiments, plans for future work, and a discussion of the theoretical interpretation of observations. The more important exchange does not appear on the agenda: it is the opportunity afforded the participants to observe those from other countries and thereby derive information concerning their training and their knowledge of subject matter, and to do some "fishing" of the status of scientific effort in other countries. If ever there is an opportunity to increase the understanding between peoples it is here. I believe we must and do obtain a fair return of information in our exchanges with the Russians since we talk about things which have been openly discussed in this country whereas they, owing to their more secretive policies, must talk about things Russian which have not been so freely published. In the present situation conferences are to be encouraged since we stand to gain much more than we lose.

Mr. KEATING. I believe you said that we have not yet worked out a definite method of bringing a satellite back to earth.

Dr. HAGEN. Yes, sir. The point here that really needs to be clarified is this: If we decided that we wish to bring one of our own satellites back to earth, then we could design it for that purpose and put in it a small rocket, for example, which on a signal from the earth could slow it down in its course and then by other means, say parachutes or balloons, we could recover it.

In that way we could effectively remove that satellite from an orbit and get it back to the surface of the earth. But if we are dealing with a satellite that has been not prepared in this fashion, or if we are dealing with a satellite over which we have no control, at the present time there is very little that we can do except to destroy it as an entity, to break it up into parts.

Mr. KEATING. While it is still in space?

Dr. HAGEN. While it is still in space, but those parts would still keep on in that orbit.

Mr. KEATING. The other method we have not definitely worked out yet, of bringing the satellite back?

Dr. HAGEN. This has not yet been demonstrated in fact.

Mr. KEATING. It is in the theoretical stage, or perhaps the development stage, but has not actually been tested?

Dr. HAGEN. That is correct.

Mr. Keating. As I understand it, when one of these satellites stops going around and starts back because it has a pull on it, it has had enough pull on it that it starts to come back, like Sputnik No. 2 just did; is that apt to burn up by friction?

Dr. Hagen. It is going to get hot. Now, Professor Whipple is an authority on meteors and he can tell you much more about this than I can, but as the satellite loses energy owing to the drag of the atmosphere, its orbit will shrink. The anomalous thing is that as it loses energy due to the shrinking of the orbit, the falling back toward the earth, it gains speed. It comes into the atmosphere at a speed that is nearly as great as the speed of a meteor and aerodynamic heating occurs. The satellite will get very hot and if it is a lightly constructed affair such as our satellites, we expect that it will disintegrate on coming into the air. If, however, it is a massive piece of metal, as Sputnik No. 2 was, then it is probably too heavy to disintegrate completely and will come right into the surface of the earth.

Mr. Keating. It will come into the surface of the earth as an entity and if somebody is standing there it will kill them?

Dr. Hagen. It certainly would.

Mr. Keating. Now, do we have any knowledge about Sputnik No. 2 that is not classified as to where it landed and in what condition it was?

Dr. Hagen. We think that we know it came down in the Caribbean and then probably landed in the water.

Mr. Keating. Was it in flames?

Dr. Hagen. It was seen as a bright object going through the sky and little bits of material were coming from the thing as it went by. Professor Whipple just said to me that he believes it did not actually go into the water in the Caribbean, but got around the world still further.

Mr. Keating. Before it hit the water?

Dr. Hagen. Before it hit the water or land

Mr. Keating. Maybe I am asking questions that I should not, but I am curious to know where the thing landed.

Dr. Hagen. Well, I think we all are, and that was true also of the first sputnik that came down. The point here is that such a large part of the earth's surface is uninhabited, or is covered with water, that it is highly unlikely that any of these satellites will ever come down where man can see it land.

Mr. Keating. Well, it depends on how many come down, does it not? It is true 70 percent of the earth's surface is water.

Dr. Hagen. Some large percentage. I didn't think it was as high as 70 percent.

Mr. Keating. Now, that would mean that 1 out of 4 of these might land on land under normal circumstance, or could?

Dr. Hagen. There are large land areas that are uninhabited, too.

Mr. Keating. That is true, but we were talking this morning about the menace of these things. It looks to me as if one of the menaces is the danger of their not disintegrating in the air and falling and doing damage to persons or property where they fell.

Dr. Hagen. I think that certainly is a menace, but the probability that that would happen, that it would fall and either damage manmade property or damage an individual, is very, very small.

Mr. KEATING. Later in these hearings we are going to have some testimony about who is liable if one of these things comes down and hits the chairman of this committee or somebody.

Now, you do not have any particular views on that as a space lawyer, do you?

Dr. HAGEN. No, sir; I do not pretend to be a space lawyer, but I would certainly feel that the man who puts the satellite in the air is the man who is responsible for its actions thereafter.

Mr. KEATING. Or the government, if it is a governmental project?

Dr. HAGEN. Yes.

Mr. KEATING. There is another thing about your testimony that was a little confusing to me. It is still confusing to me, but all you have to tell me is that it is not anything for a public hearing:

Do we know where Sputniks Nos. 1 and 2 came down, or is it still a mystery?

Dr. HAGEN. I don't believe we know exactly where.

The CHAIRMAN. Do you think anybody else knows?

Dr. HAGEN. I am not so sure about Sputnik No. 2, but about No. 1, I don't believe anybody really knows.

Mr. KEATING. Do we know whether No. 1 actually disintegrated before it hit the surface of the earth?

Dr. HAGEN. There is some evidence that it did, but we do not know this for sure.

Mr. KEATING. You talk about advanced Vanguard, as I think you mentioned the project. I think you said, and you set me straight on this, that you could now put 75 pounds in orbit?

Dr. HAGEN. No; I did not say we could do it now. Let me review what I should have said, let us put it this way: The improved Vanguard which should be in being later this year will be capable of putting some 40 pounds in orbit. The next step beyond that would be the step where we could put some two or three hundred pounds in an orbit. Using the Vanguard vehicle with known and in-hand pieces of hardware, just using other combinations, it is possible to put as much as about 900 or 1,000 pounds into a satellite orbit.

Mr. KEATING. When could you do that if you had some funds?

Dr. HAGEN. This would take another year or two.

Mr. KEATING. If you had the funds and were given complete support and you were given the project of putting a man into space—I recognize your reluctance about doing that now, but suppose it were decided to do it. Apparently there are a lot of volunteers getting ready to do it, and getting this man back alive, and, of course, we would not put anybody into space unless we thought we would get them back alive. How long would you want for this project?

Dr. HAGEN. This would involve, too, surely that the man do some useful thing while he is up there?

Mr. KEATING. He had better be of some use to get him up there and alive, had he not?

Dr. HAGEN. Yes. I think it gets very problematical as to what the time would be, but we would be in a position hardwarewise to do this in another 2 or 3 years. It is something that one would wait at least that long for. The hardware is going to be available before that time, but it will take time to bring it together and to take the necessary precautions in the design of the capsule in which the man rides, in order to bring him safely back into the atmosphere.

Mr. KEATING. Now I do not want to accentuate any interservice rivalry, but we have had testimony, I think, from Dr. von Braun that if he had that "go" sign tomorrow he could do it within a year.

Dr. HAGEN. Perhaps he would. I think one should be very careful in defining his terms in giving an estimate like this. That is why I asked the question like that. I would want to qualify it by saying that a man would be put up in a vehicle so that he could do useful work. The other thing is that a man could be safely recovered.

The CHAIRMAN. I think Dr. von Braun said something about 160 miles in space, staying up there a few minutes.

Dr. HAGEN. That is a different thing altogether. He was talking simply of a rocket shot, in which the man is shot up in the air and brought back down. I was talking in terms of a satellite in which a man would make at least one circle around the earth.

Mr. KEATING. And that equipment be so designed so as to be able to talk about?

Mr. HAGEN. Yes.

Mr. KEATING. I think that is correct.

Now, can you do the other job in a year, or do you think that is a little too optimistic?

Dr. HAGEN. I am not so sure. I would think it might be a bit optimistic.

Mr. KEATING. Now, I respect your views, Dr. Hagen, and these questions are not intended to be critical of your views, but do you belong to the school of thought which believes we should not try to put a man up there and bring him back until we can put him to some useful job?

Dr. HAGEN. Yes, sir. I think this is so. I believe that the order in which we should do things is this: that we should not use the man as a guinea pig. We have other ways of doing it.

The aeromedical people have plans that will allow us to measure all of the critical areas and items ahead of time so that we will know all of the things that we need to know about the survival of man in a space vehicle. We should learn those things without jeopardizing the life of an individual. Once we have learned them, then we should prepare to put a man up there to serve a useful purpose.

Mr. KEATING. I want to ask you one other question, which again may border on security. It has to do with fuels.

Do we know the type of fuels which the Russians are using?

Dr. HAGEN. No. I don't think we know as a fact what the fuels are. As I pointed out earlier, they could be using essentially the same chemical fuels that we are.

Mr. KEATING. In your judgment are they?

Dr. HAGEN. I believe they probably are, although I am also sure they are experimenting with more exotic, higher energy fuels.

Mr. KEATING. I have heard of that word "exotic" time and time again in this reference. Does that mean a higher energy fuel?

Dr. HAGEN. No, sir; I believe the meaning of that word is that it is foreign or strange, and it has been used a lot because the use of the higher energy fuels is foreign to our experience.

The CHAIRMAN. Are there any further questions?

Mr. KEATING. Yes, just a couple more, Mr. Chairman.

You referred to the fact that your top men, five of them I think, had a salary of around $12,000 a year.

Dr. HAGEN. Yes.

Mr. KEATING. Dr. von Braun testified here that his own salary was $19,000. He seemed to show no reluctance in testifying to that. He has this group around him down there, who are under civil service, as I understand it. Yet their salary scale, I have the impression, is higher than yours.

This $12,000 is not the top which scientists could draw under your program, is it?

Dr. HAGEN. Almost. That is, if they wanted to follow the policy of not having the man earn more than the man for whom he works, $12,000 would be pretty nearly the ceiling.

Mr. KEATING. Do they not follow that policy in the Army?

Dr. HAGEN. It sounds as though they have classified some of the positions at a higher level than our positions have been classified.

Mr. KEATING. I want to ask you a word or two about this bill, about which you have testified.

You have expressed preference for a small Board, perhaps a 5-man Board full time, as against this 17-man Board, part time.

Another possible approach here is to have this larger Board, but to make their duties purely advisory.

In other words, this bill, as it has been introduced, makes the 17-man Board the overriding authority above the Director as to certain very fundamental things. I recognize the unwieldy character of that. Now, if you shifted that so that they were advisory only, then you could have a more centralized authority in one man, the Director, without the intervening 5-man Commission, could you not?

Dr. HAGEN. Yes, sir; that is true.

The way it is written it says:

The Board shall be consulted by the Director.

Now, the meaning of these words is not clear to me. The Director could consult the Board, but then ignore their advice, I believe.

Mr. KEATING. I suppose.

Dr. HAGEN. I do not know how one would interpret those words. The interpretation, the restrictive interpretation that I would put on them, is that the Director should consult the Board and abide by their recommendations.

Mr. KEATING. Otherwise, as to these very fundamental and far-reaching matters, it is rather meaningless if the Director is going to have complete carte blanche to do everything he wants to do after he is consulted.

Dr. HAGEN. Yes.

Mr. KEATING. As between plan A whereby you have an advisory 17-man or large Board, plus an operating Director, or, B, a plan for a 5-man operating group with a Chairman who is Director, which of those 2 plans do you like better?

Dr. HAGEN. I prefer the smaller group and would expect that the smaller group would be composed of full-time people. I should probably go back to the discussion this morning and I do believe that I probably confused the issue a little bit by suggesting that they might perform other functions.

Let me state this: I believe that this group should have as its function solely the determination of the policy that the agency is to follow and that the group would determine that policy.

The Director who would be the chairman would be the executive chairman of the group.

Mr. KEATING. I see, because under section 6, subsection 3, there are very extensive operating authorities given to this agency. Your idea is that the Director would be the one who would be responsible for the operation and the Commission or Board of, say, five men, simply for policy problems.

Dr. HAGEN. Yes.

Mr. KEATING. Now, in the Atomic Energy Commission, are not all the members jointly responsible for operating as well as policy?

Dr. HAGEN. I am sorry to say that I do not know.

Mr. KEATING. I think that is something for this committee to look into because that has been quite a successful method of operation and it may be that we should pattern this more after that than in the way we have it here now.

Since you favor a department of science and technology or technical man in the Cabinet, if you did not have that, and perhaps we are not ready to take that step yet, you would share my view, would you not, that the Director of this Agency have the equivalent of Cabinet status in that he would sit with the National Security Council and in Cabinet meetings and have a voice in the formulation of policy at the very highest level.

Dr. HAGEN. Yes, sir; I believe this would be necessary, at least as far as the Security Council is concerned.

Mr. KEATING. Do you think that we should incorporate in this legislation to effectuate that, or should we leave it to Executive action?

Dr. HAGEN. I do not believe I am competent to discuss that point.

Mr. KEATING. That is all I have, Mr. Chairman.

Dr. HAGEN. May I say one other thing. In answering the questions here, because of the urgency of the job that I know this committee has, I have not held back any of the answers. All of the answers, however, should be considered to be my personal opinion and not to express the attitude or the opinion of the Department of Defense.

The CHAIRMAN. That is understood.

Mr. Ford?

Mr. FORD. Dr. Hagen, when you were given the job as Director of Project Vanguard, did you feel at that time it was a sound and feasible project for the stated purposes?

Dr. HAGEN. Yes, sir. If I had not felt at that time that it was sound and feasible, I would not have taken the position.

Mr. FORD. I have always been impressed with your testimony, when you and others from Dr. Bennett's office have been over to testify as to your expenditures, with the fact that you never made statements that seemed to be tooting your own horn, so to speak, forecasting success, as might easily have been the case.

I was looking through the testimony of the last 2 years this morning on the appropriation requests and never once were you categorical in your statement, that it would be successful within the IGY.

It has been very successful and I want to compliment you on the accomplishment that you have made to date and which I am sure you will have prior to the end of the IGY.

Are you going to be able to do this job with the $120 million that was made available?

Dr. HAGEN. It is not quite $120 million. I hope we will be able to do the job with the funds in hand. The project is funded up to $110 million, plus another small amount, less than $2 million, for tracking. Now, it does appear that except for some unforeseen calamity we will be able to finish the job with what we have in hand.

Mr. FORD. Doing the job with the funds allocated is an achievement in itself, I might say.

Dr. HAGEN. I hope we can bring it about.

Mr. FORD. Would it be your recommendation that at the conclusion of Project Vanguard you will recommend an extension of Project Vanguard or should we put emphasis on the other Department of Defense projects in this area?

Dr. HAGEN. Sir, I believe this: In Project Vanguard, we have necessarily built up a facility for doing a particular kind of work which is an asset as far as the Department of Defense and the country are concerned. It it a group of people tailormade to do a specific kind of job. I believe that it would be just a waste of our national assets to allow this group to dissipate and then have to start all over again with another. For that reason, I hope that in the plans for the future space research there will be a place for Project Vanguard and that there will be an extension of the kind of thing we have started.

Mr. FORD. Project Vanguard is a nonmilitary operation?

Dr. HAGEN. Yes, sir; even though it is in the Department of Defense.

Mr. FORD. It would seem that if this new Agency is set up, then the organization to which you refer would be a natural starting point within this new Agency for its overall work in the area of space and so forth?

Dr. HAGEN. Yes, sir; it could be. That will depend a great deal upon the method of operation chosen by the Agency. As I see it, they could go into a department and absorb unto themselves those parts, or those functions they can most properly use to build up their organization, and as I read the bill the authority to do that is written into the bill.

That is one way of operating. Another way would be for the Agency to administratively take over the group, for example, the Vanguard group, but allow it to function in its present location. Now, this may be the only way that Vanguard per se could continue in doing this kind of work.

Mr. FORD. I suspect you have had your hands full trying to make this project work?

Dr. HAGEN. Yes, sir.

Mr. FORD. Have you or your people had an opportunity over and above that very great responsibility to think of a logical follow-up of Project Vanguard?

Dr. HAGEN. Yes, we have. I personally have spent a good deal of my effort and energies doing just this. We have presented from time to time a forward-looking program that goes beyond Vanguard, that is hinged on the fundamental notion that this vehicle was so designed that it not only would be a most efficient vehicle to put a satellite in orbit, but would be sufficiently flexible to permit change and improvement. So the programs that we have recommended have been based

on improvement of the Vanguard vehicle to give it the capability of handling bigger things or going greater distances.

Mr. FORD. Do those recommendations go to ARPA at the present time?

Dr. HAGEN. At the present time, yes; they would go to ARPA. They did, antedate ARPA, however.

Mr. FORD. Have they been actually submitted in concrete form?

Dr. HAGEN. Yes; there have been submissions in concrete form.

Mr. FORD. Approval as of now?

Dr. HAGEN. As of the present there is no approval of any further program.

Mr. FORD. I gather it is possible that at the conclusion of Project Vanguard you might have some hardware that could be used for an extension of Vanguard plus the talents of the individuals who work on Vanguard.

Dr. HAGEN. If by hardware you mean rockets, no. At the conclusion of Vanguard, I trust we will have launched all of the rockets we purchased to do the job. What will be left after that is the organization and the facility and the big computing facility, for example, and then the laboratory facilities for instrumenting the rockets, the facility at Patrick for launching these rockets, things of that nature. But the actual rocket hardware I hope will be all shot away.

Mr. FORD. Looking back to the period when the decision was made that Vanguard rather than Orbiter would be the United States IGY satellite program, do you feel that a wise decision was made as far as Vanguard is concerned?

Dr. HAGEN. I believe, looking at the situation in the whole, a wise decision was made. We have achieved a satellite in the IGY that has been, as many wanted it in the beginning, divorced from military hardware, purely a scientific venture. This, I think, has been to the good.

The question as to timing is one of those hypothetical things. It is quite possible, had the choice been made in the other direction, a satellite might have been in the air earlier than it was.

Mr. FORD. Again I want to congratulate you and your organization, Dr. Hagen, not only for the success of the venture but the fact that the money you got you apparently wisely used and are not going to need any more to complete your operation.

The CHAIRMAN. Of course, the importance of an observation like that, Doctor, as you appreciate, coming from a very, very, very, very important member of the Committee on Appropriations, ought to be very valuable.

Mr. FORD. When people come up with that kind of record we are apt to give them more money next time.

The CHAIRMAN. Then I have made a truthful observation have I not, Doctor?

Dr. HAGEN. Yes, sir.

The CHAIRMAN. Then a very, very, very, and a few more "very's".

Mr. FELDMAN. Doctor, you used the words earlier in your testimony "conflict of interest," and I believe it was in connection with the Advisory Committee as it appears in the legislation before us at the moment.

Would you indicate in what way there might be a conflict of interest in connection with such an advisory committee?

Dr. HAGEN. Yes, what I was thinking about is this: When one is about to choose such a Board, I think he should look for competence in the individual rather than choose an individual because he represents a certain area in the community. When the individual serves on the Board as a part-time employee, really, it would seem to me that his basic loyalty would be to his full-time employer and that it would be very difficult for some individuals to separate their loyalties and to make unselfish and unbiased decisions on the Board. There could very well be a tendency in time to do, if I may use the word, a kind of logrolling where A will do something if it will satisfy B and in return get his favor. This kind of thing would be very unfortunate. That is one of the reasons I so strongly recommend that the members of the Board be chosen for their ability, be chosen over a wide area, and be full-time employees.

Mr. FELDMAN. We have laws on our statute books dealing with conflict-of-interest situations.

Dr. HAGEN. I realize you do. I do not really mean to create the impression that this action would be intentionally dishonest. I believe it is the kind of thing that skirts the law, yet is bound to come up when you are dealing with a group of people, that one must always consider how his actions affect the others.

Mr. FELDMAN. Doctor, we have had testimony before this committee from various witnesses stating that their experience with the AEC has been excellent.

Now, in the AEC—when I use the words "AEC" I mean the Atomic Energy Commission—in the act itself there is a provision for military liaison. As I just stated, that has functioned very well.

Would you recommend a corresponding provision in the legislation that we have before us at this time?

Dr. HAGEN. Yes, I would, and this goes back to a question asked earlier this morning. It would be unfortunate and perhaps unwise to have Department of Defense or military membership on the—suppose we did have a 5-man Board—on this 5-man Board because of the desk and not of the man. However, there is bound to be a great interplay between this Agency and the Department and for that reason I believe the same liaison mechanism that is used for AEC would be helpful.

Mr. FELDMAN. Doctor, it might be difficult to write a substantive provision that the Administrator or Director or Chairman of the Commission be on a level equal to that of the Security Council or a high level, but that could be included certainly in the declaration of policy in a bill. Would you favor such a declaration?

Dr. HAGEN. Yes, sir, I certainly would.

Mr. FELDMAN. I think we are agreed the scientific resources and talents of this country must be harnessed effectively. I think you said that this morning about the space program. What would your reaction be to developing or providing a central register of such technical talent? Could you develop for us the possibilities for some plan to corral our trained people?

Dr. HAGEN. I wish I knew how to do it. If I did I would tell you but I think it is a monumental task. It has been attempted. I believe there are on IBM cards a compilations of the talents of individuals in this country that was started, I am sure, during the Second World War. But it is a difficult thing to manage——

Mr. FELDMAN. It would have to relate to a specific field and so on. This is a monumental task but if it could be done would you consider it worthwhile?

Dr. HAGEN. If it could be done, I certainly think it would be worthwhile. It is a disgrace, to waste the manpower and the brains in this country when we so sorely need them.

Mr. FELDMAN. It might also prevent any stockpiling of scientists by particular companies, is that right?

Dr. HAGEN. That is right, and that is why I believe it would be so very difficult to implement such a thing. You would have to have not only the capabilities of the individual but you would need to know the inner workings of the company, to know how the man was being used. In our way of doing things, this is a very difficult thing to see.

Mr. FELDMAN. I believe it would be a difficult thing to do completely, but at least an attempt should be made in that direction. Is that your feeling?

Dr. HAGEN. I feel that an attempt should be made in that direction, yes.

Mr. FELDMAN. Dr. Hagen, were you consulted during the course of the drafting of the proposed bill?

Dr. HAGEN. Of this bill?

Mr. FELDMAN. Yes.

Dr. HAGEN. No, sir.

The CHAIRMAN. At that point, will you carefully look it over and, as I suggested before, make your recommendations or suggestions to the committee?

Dr. HAGEN. Yes, sir, I will.

(Material referred to is as follows:)

The proposed bill, in my opinion, is basically a good one, and the NACA is a competent scientific organization. Apart from the discussion made in my testimony I have these specific recommendations and suggestions:

Section 2, page 2, lines 4 to 10. This should be carefully worded so as to not exclude participation by components of the Defense Department which have general capabiilties which also contribute to weapons programs.

Section 2 and section 6 (a). The mission of the agency should explicitly include exploration. Measurements are presently being made and operations conducted in space using scientifically instrumented but unmanned vehicles. When the preliminary investigation and probing have been completed it may well be decided that it is in the national interest to send a manned space vehicle to a location away from the earth. This bill should authorize the space agency to conduct such manned exploration.

Section 3, line 10. The Director should also have authority to assign portions of the program to other agencies where capability exists.

Section 4. The best-qualified men should be on the Board. I see nothing wrong with the majority coming from Government if they are the best men.

Through a reference to section 4 (a) 2 the wording in 4 (b) becomes too restrictive. There are many people of high competence in Government service and the country should not be denied their services as a Chairman of the Board.

Section 5 c. The interpretation of the word "consult" should be clarified. For example, does consult as used here imply obtaining approval?

Section 6 (b) 2. Giving a new agency authority to operate outside the Classification Act of 1949, supposedly to help attract high-grade personnel on the basis of equal pay for equal work, is not a proper solution of the problem. This approach tends to degrade the civil service system. A recommended procedure, more fair to existing agencies and employees, would be to adjust all civil service salaries in this area of work on a basis of equal pay for equal work.

Mr. FELDMAN. Your project began in the fall of 1955 and your first satellite went into orbit on March 17, 1958. It took you over 2

years. Why was that, when it took the Army only a few months after the go-ahead to launch a satellite?

Dr. HAGEN. I think the best way to go at that is to go back to 1955, at the time the decision was made to use project Vanguard. At that time there was no hardware in this country capable of launching, or even acting as the first stage of a vehicle which could launch, a satellite that would satisfy the needs of the International Geophysical Year program. The decision was made then to go ahead with Vanguard. Now, we did proceed with Vanguard. We had a sense of urgency within the project, and we had certain priority restrictions upon us. We proceeded as rapidly as we could.

One of the competing projects was the Army project which was referred to a moment ago, the Orbiter project, based on the then Redstone vehicle. That, however, had a capability of launching into orbit, I believe, five pounds, which was not sufficient for the IGY purposes.

I have read recently that the Army continued the work on the Redstone launching vehicle, which then became the Jupiter-C, as a reentry vehicle and it so happened the geometry of this reentry test vehicle was just the geometry needed to make a satellite launching vehicle.

So that when the Army was requested in October or November—November I believe it was—to come into the program and aid with the backup, they had already developed the vehicle as a reentry test vehicle and what remained was to instrument a satellite to go into it.

Mr. FELDMAN. The Army insists it could have launched a satellite in 1956 but was denied the go-ahead.

Can you state any reasons why the so-called Stewart Committee gave you the job in 1955 instead of to the Army?

Dr. HAGEN. I partially answered that before. Because the Committee believed that the Vanguard vehicle proposed at that time had a greater chance of putting a larger satellite in orbit during the IGY than the Redstone vehicle.

Mr. FELDMAN. The Army and Air Force plan to use stages of the Vanguard in their shots to the moon? This must indicate that they think a good deal of the Vanguard.

Dr. HAGEN. Yes, sir. We take that as a compliment on the design of the Vanguard vehicle. I think the point that is of interest here and perhaps the answer to your question is that the Vanguard vehicle is designed as a very efficient rocket. We—I mean the people who worked in the group and who did this design—realized that the efficiency of the rocket must be a maximum in order to achieve its purpose. This means that they did everything to reduce the deadweight. So they came up with stages in that rocket, with the first, second, and third stage; each of them is a highly efficient rocket. The third stage is one of the most efficient rockets that we have in this country today. In the same way, the second stage is a very efficient rocket for the purpose for which it was designed. These two stages are the two that are being placed on top of the other vehicles to do this moon shot.

Mr. FELDMAN. One last question, which is a technical one.

I have heard that a satellite at a certain distance from the earth, 22,000 miles or so, would stay over the same spot on the earth all the time because the satellite travels in its orbit just fast enough

to match the spin of the earth on its axis. Why not place one over a given city or other interesting place to keep an eye on that spot?

Dr. HAGEN. I am going to have to talk with my hands to answer that one.

If we were to launch a satellite in an orbit around the Equator, then this statement could be exactly true. If it were put up over Quito, Ecuador, for example, then as the satellite goes around in its orbit the earth turns on its axis and they both go at the same rate. The period in the orbit is determined by how far out we go. So if the satellite were started out over Quito, it would stay over Quito, going at the same rate the earth turns.

If we tried to do the same thing for Washington, we would be in some difficulty. If we inclined the plane of the orbit of the satellite to the Equator at 38 and a fraction degrees, then at the top of its swing the satellite would be over Washington. But one thing is important in this satellite discussion, and that is that the plane of the satellite's orbit has to contain the center of the earth. So if the satellite starts out over Washington, it does not run around the parallel of latitude, 38°, it goes down across the Equator and then back up again.

Now, if we make this satellite have a 1-day period, then it goes around its orbit at the same rate the earth is turning; it starts at Washington, but as the earth turns it goes south and then comes back up again, so that it would swing all the way from Washington down to Santiago, Chile, and back again.

Therefore, if you did that kind of thing and your latitude is north or south of the Equator, instead of staying overhead the satellite would appear to move in a north-south line once a day.

Mr. FULTON. You were talking, of course, about an unpowered satellite and one that is not possibly put up with a twist.

Dr. HAGEN. Yes, all of the satellites that I have talked about, I think, have been unpowered. That is, once they are put into an orbit, there is no further power. They just coast along.

Mr. FULTON. If there were an alternating rocket thrust built into the satellite, you could at times correct it because it is merely a 38° variation over a 12,500-mile arc.

Dr. HAGEN. You would have to use a lot of energy to continue to do this. In modifying the motion in that way you would have to assert a thrust and control the direction of the thrust continuously.

Mr. FULTON. By accelerating at a certain period, would that help you out, because when it starts away from the Equator or comes back toward it—that is, the satellite in its orbit—in regard to the rotation of the surface of the earth it is either going faster or slower.

Dr. HAGEN. Unfortunately, once you stop accelerating it then it will go along in a classical orbit. The orbit must always contain the center of the earth, so that if it is north of the Equator when you stop your acceleration, then it is going to pass south of the Equator in order to make the plane contain the center of the earth.

Mr. FELDMAN. Would you care to comment on what you think the Russians are doing now in a specific way on the space race?

Dr. HAGEN. I do not think I can say much in addition to what I have already said about them.

I believe they are moving forward and you can anticipate new surprises.

The CHAIRMAN. Any further questions?

Thank you very much, Dr. Hagen. You have been very patient and very helpful. For myself as chairman of the committee and the other members of the committee, I express to you our sincere thanks.

Dr. HAGEN. Thank you, Mr. Chairman.

The CHAIRMAN. The next witness is Dr. Fred L. Whipple, director of the Smithsonian Astrophysical Observatory at Cambridge, Mass.

We are very glad to have you with us, Doctor. We hope to benefit very much from an expression of your views as we have all other witnesses who have appeared before us.

Have you a prepared statement?

STATEMENT OF DR. FRED L. WHIPPLE,[10] DIRECTOR, SMITHSONIAN ASTROPHYSICAL OBSERVATORY, CAMBRIDGE, MASS.

Dr. WHIPPLE. I have no prepared statement but I should like to make a few remarks in lieu of that.

The CHAIRMAN. Go right ahead, Doctor.

Dr. WHIPPLE. I deem it an honor and indeed a great privilege to have an opportunity to discuss this bill before your committee.

In making a general comment on the bill, I must say that I am of the considered opinion—I read it very carefully indeed—that this was devised with extraordinary wisdom and foresight and I feel that the bill is an extremely important one to further science and for the future security of our country.

My connection with this program is through the satellite tracking program of the Smithsonian Astrophysical Observatory.

We have been assigned the task of tracking the artificial earth satellites of the International Geophysical Year program, by optical means. We started on this with very limited funds to begin with, 2 years ago in January, and we were planning a culmination of the program in the middle or early part of this year.

The program consists of two major portions. The first is the Moonwatch program instituted to utilize volunteer observers throughout the world who could make satellite observations with small telescopes. That program has worked out, I think, quite successfully.

I think it may be of interest to this committee to know that the Russians set up a volunteer, at least a similar program, following the same principles that we have used, for some 70 stations in the U. S. S. R. We have about 126 stations of volunteer observers in the

United States and somewhat over 100 in other countries as a part of the International Geophical Year program.

The major portion of our program, however, was to set up 12 observing stations with large photographic cameras for precision observations of artificial earth satellites throughout the International Geophysical Year. Those stations are mostly set up and are being completed at a rapid pace today.

The program has required the cooperation of a number of countries all over the world and we have found extremely good assistance in so conducting the program.

I may say for the program to be successful in the sense of sufficient observations of many satellites, or of some satellites over enough revolutions, it will be necessary for this program to continue on beyond the International Geophysical Year. At the moment we do not know a source of funds for the continuance of that program. However, it was set up to operate to June 30, 1959, instead of December 31, 1958. So we have a bit more time to search for funds in the future.

But I think this will illustrate a general problem of the high-altitude and space programs in this country; funding not only does not exist beyond the end of the International Geophysical Year or thereabouts, but there is no clear indication of any sources of funds for the continuing of the space programs after that time.

Now, I feel that the scientific exploration of space is of vital importance to our country. It has been stated here that we are following the leader. I do not agree that that is a proper connotation. The leader happens to be going faster than we are. We might use the analogy of a racetrack or a cinder track, where the course is clearly defined. The leader is ahead of us and only in that sense are we following the leader in this program.

If he were outside the cinder track, off in the bushes somewhere, then we certainly would not follow him and we could relax a great deal in contemplating this program. But he is indeed carrying on an extremely effective program, begun immediately after World War II, and so far as I can ascertain from the information I have available, has been pursuing it with a clear-cut intention of exploring space and of mastering space.

So I feel that it behooves us to act wisely, effectively, and strongly in this matter. That means that we must coordinate our efforts and utilize our manpower to the best possible advantage.

For that reason I feel that we must have an organization of the type you have visualized here with a very high status in the Government so that it can operate at a comparable level with the Defense Department and other agencies that are interested in this problem. I think this national space agency should be the coordinating agency for the activities in space research. That does not mean that it should control this activity, but it should be in a position of coordinating. I do not see any agency that is in that position at the present time.

The organization should be at a high level and it should be, I think, independent of the military, not because the military are not competent; they are indeed competent; they are also very conscious of the significance of science in the defense of our country. I have made the statement privately a number of times and I would like to make it publicly here: that since the end of World War II, in my opinion, outside of the academic world there is no group in the United States that is more conscious and appreciative of the significance of science

in the future security of our country than is the military. They have gone to great efforts to promote basic science. I think in many cases they have "bootlegged" basic science into their programs because they realized it was necessary and because, until very recently, we had no national organization to fund the basic research that would be of value to them.

But in this particular case. I feel that the space exploration should not be under the control of the military because their objectives are not the same as the objectives of this space agency should be. The interest of the military must center on specific defense equipment. They must, by the nature of their operation, concentrate on shorter range goals than basic research.

I do not think we should consider the problem from the viewpoint that the scientists should be under the control of the Government in exploring space. There are two aspects to this problem, in my opinion: (1) The United States Government should give its scientists the opportunity to make the basic explorations that are so important to our future. (2) The United States Government should then, of course, adopt policies as to the utilization of space and what is to be done with the scientific results and the instrumentation that result from the program. This point of view is slightly different from the one mentioned this morning.

It is my opinion that there is no better expenditure of the taxpayers' money, for the future of this country, than in basic research. It pays off in the long run with greater dividends than any other expenditure of funds that we make in terms of the future of our country, the future of our ideals and of our democracy.

That is why I feel so strongly that this national space agency is a vital and important agency for our country.

There would be a great many very tangible and explicit benefits. I do not want to take much time in discussing these but I should like to point out, for example, that weather forecasting, in my opinion, will become a science instead of an art. When it is possible to make observations continuously over the entire earth's surface of cloud coverage, the temperature, the water vapor content above the reflecting surface and the wind, and on a daily basis, the satellites will then provide the information necessary to give us a sound theory of weather. This theory, coupled with the great computing machines to utilize the data and to apply the theory in terms of the observations, will make weather forecasting an exact science. I predict that knowledge of weather alone, in its value to the country, will greatly outweigh the cost of the entire program.

I think there will be many, many great advantages that will come, as we might say, on the side.

One example is the use of a substitute for a man in a satellite. If the scientist conducts his program he is going to put as few men as possible up there because sending them is extremely expensive. Scientists, I think, are a most economical, carefully minded people in this respect, at least as careful as anybody in this country as a group.

It is uneconomical for scientific purposes to put man up there to operate instruments. It is going to take time, however, to develop substitutes.

The first move will be to put men there. But at the present time, the telemetering systems that have been developed in rocketry can send back and read more than a hundred instruments several times a second

with an accuracy of 1 percent and send the data back to the earth. It is clear that the crew necessary to make that many observations in space would require a ridiculous amount of equipment.

Mr. McDonough. Will you delineate the variety of information you can get by telemeter?

Dr. Whipple. This information is limited always to the reading of scientific equipment. It can be a voltmeter, a cosmic-ray counter, a meteor counter, an ultraviolet-radiation measuring device from the sun, and it could be a television receiver to transmit a picture back.

On the other hand, the problem of servicing equipment in space is extremely difficult. I visualize, in the long run, the use of a device, which, for want of a better name, I call a telepuppet, a remote-control device, a type of robot. By television eyes it would enable us to see within its space vehicle. It would have some motion within the vehicle and would have ability to follow the motions of the operator's hands, the operator being on the ground. The telepuppet in space would then duplicate the actions of the operator's hands on the ground and therefore make servicing possible.

Now, this type of equipment is already in existence on a minor scale in the "hot" laboratories, and is a device that should be pursued. This is an example of the type of valuable side development possible.

I point out that when such devices are well developed they will have multitudinous practical purposes on the earth so that mankind will not be endangered in doing dangerous work. I can see the time when telepuppets will do our unusually dangerous mining underground so that we will not have to worry about mine cave-ins, explosions, etc., and also deep sea operations.

This type of benefit will come on the side, as it were, without even being considered part of the program, and this is only one of them.

Now, I want to mention again another reason why I think space exploration should be under civilian scientific control. Let us take the long-range point of view. The scientist wants to understand space, the phenomena that occur there; he will, therefore, conduct studies that may not have immediately obvious useful purpose. But we have found from experience, and I need not belabor this point, that researchers into the unknown inevitably pay off in practical benefits. Here I think there is no question but what the benefits will be enormous in comparison to the cost.

Now, I must point out again that I hope that the operations here will remain in an unclassified level in terms of security classification, insofar as is possible. This is very important. I do not want to go into details here but I have encountered before this question of classification, particularly a number of years ago in the upper atmosphere rocket research program with the RDB. At that time there was pressure to classify that research work. The main argument, I understood at that time, was that the measurements of the high atmosphere were expensive and therefore should be classified.

This argument I thought was not a correct one, and it has been interesting to note what has happened.

The results were not classified, for which I was very pleased, and in discussing problems of such fundamental data as the density of the high atmosphere within the rocket range, the Russian scientists with whom we have talked during the past year have seen our published data and only recently have presented their own material.

I saw the results of theirs last fall for the first time at the meeting of the International Geophysical Year here in Washington.

The interesting point is that the Russians were not taking our results about the upper atmosphere and utilizing them directly as fact. They were highly critical of our results, and, in fact, said they were not so good. They considered theirs better than ours in spite of the fact that we have had an extremely good upper atmosphere research rocket program carried on by extremely competent people.

My point is that this sort of information is of great value to our other scientists and it is very doubtful, in terms of basic research, that we are going to be much ahead of the U. S. S. R. in any zone. We may be ahead here; they ahead there. The net result is the improvement of science, which is good for the world internationally as well as good for us.

Mr. McDONOUGH. Did they have any comparative data that was better at the time they criticized ours?

Dr. WHIPPLE. I think they did. They were criticizing us particularly with regard to density and temperature above an altitude of 100 kilometers. I would not want to make an absolute statement, but it is my impression that their data were better than ours.

Mr. McDONOUGH. Is that not a normal attitude for them to criticize what somebody else does, to indicate that theirs is superior?

Dr. WHIPPLE. I think every scientist tends to criticize somebody else's work until he is sure of the right answer.

Just one last point about the security angle: Security officers take the point of view that any information that might be useful to the enemy or potential enemy should be classified. This, of course, is not the point in question at all. Every time any item is classified there is a certain loss to us. The question is whether the benefits they will gain outweigh the price that me must pay in loss of efficiency or otherwise; if that benefit then is greater than our loss we will gain by classifying; and the material should be classified. But the problem is very difficult. The tendency is to overclassify and therefore hamstring our own operations.

Mr. FULTON. Would you yield a minute?

Did it not shock you a little when you heard the Russians were not playing open with us on the IGY and suddenly we found that they had information that our very open-minded scientists had not known about, when we had given full exchange?

Dr. WHIPPLE. They said they were going to put up satellites. When we asked them as to masses, were they planning payload satellites smaller than Vanguard, for example, their statement was that they were considering some as small but others much larger.

I would say that the only case so far in which have not played square with us is with regard to the frequencies that they used in their radio transmitters. On the other points they did not state the times of launchings but they told us they would not state the times of launchings until they had made successful launchings.

Mr. FULTON. Have they given any United States scientists the results of their Sputniks I or II or told you the codes they were operating around the earth?

Dr. WHIPPLE. Our opinion and theirs agree in that the observation material should be primarily under the cognizance of the country sending up a satellite. I should expect that they will transfer to us

measurements they have made of the transmissions from our satellites. I think this will be a good test as to whether they transfer to us their tapes and records of our radio transmitters.

They have very little other information that they could transmit to us.

This summer will tell the story as to whether they do indeed give us the scientific information that they have obtained. Reduction and interpretation are laborious and time-consuming while telemetering codes are of little use to others.

I may say on one point they have transmitted a very useful piece of information, that the first sputnik satellite, the sphere, was not punctured by meteors in space.

Now, I feel that, in terms of this whole effort, the National Space Agency can indeed make more efficient, and in fact most efficient, utilization of the manpower in this country. I feel that it is extremely important that we do not allow any of our resources such as our scientific groups, organizations and facilities who are able in space science, to wither away.

To my knowledge, for example, there is no coordinated program continuing the upper atmosphere rocket research beyond the International Geophysical Year. I do believe that some of our military services are carrying on their own programs but I do not know of any coordinated program to continue this research, which is absolutely vital.

We are making a good start on a very much less expensive rocket study of the high atmosphere. I feel that such an agency as proposed here is extremely important in coordinating the efforts of all of these groups in the country.

This means, of course, that the Astronautics Agency must have knowledge about who or what groups are able to do this and what groups are able to do that; therefore the operation must be very specifically coordinated with the military programs. It means, of course, that the Agency must be well funded so that it can let contracts to the universities, to commercial organizations, and, possibly, to the military organizations. It must have close liaison with the military so that when a special problem comes up, particularly a large effort, a decision can be reached as to whether that project will be conducted within one of the services or by the Astronautics Agency.

It is extremely important that this coordination be made so that we can utilize the force, the manpower that we have. And it is particularly valuable to keep these technical and scientific teams going in an effective manner so that they have confidence. That means that the Agency needs to have power to commit, in one fashion or another, activities for more than a year. These are often long-term projects and it is absolutely vital that the team conducting the project know that it is going to be financed long enough to complete the job.

That does not mean that we have to take action on a crash basis. I think there are a few things that need to be done, a few decisions to be made on a crash basis, to assure that we continue the programs we have started and keep the teams in this area operating properly.

But for the long-term program, I should think it is vital that this National Agency be set up on a very sound foundation, that it be planned so that it will continue on with long-range goals not limited by 1, 2, or 5 years, and so that it can then plan and organize a con-

sistent long-range program for the exploration of space and the science that goes with it.

The CHAIRMAN. And to expand, I assume you have in mind?

Dr. WHIPPLE. I would assume to expand to a certain extent. I have no idea how great this expansion should be. That is very difficult to see at this time. It depends, for example, on miniaturization.

It has already been demonstrated that we can put an enormous amount of equipment in a few pounds in space, I do not see how one does that with a telescope, which I think is very important, but even so the weights can be reduced. So it is difficult to say how expensive it is going to be.

Clearly in problems of physical exploration, sending men about the moon and to the moon's surface, one is going to have to go into more expensive programs.

But I do think that, if this is a civilian-controlled agency, it will be done in the most economical way possible and that the scientists generally like to do things neatly and generally like to cut administration as far as possible.

The CHAIRMAN. I meant expand, speaking of the related activities within the agency created.

Dr. WHIPPLE. Yes; I would visualize considerable expansion in that direction.

The CHAIRMAN. That is how I use the word "expand."

Dr. WHIPPLE. I am certain in my own mind that the proposal here is going to demand a complete change of viewpoint on the part of the NACA, National Advisory Committee for Aeronautics.

The CHAIRMAN. It is a complete reversal.

Dr. WHIPPLE. Yes. The policies here are quite different from the practices and policies of NACA, as I understand them, and involve, it seems to me, a great deal of contracting to commercial agencies, universities, nonprofit organization, and possibly the military.

As I understand it, the NACA has had the policy of doing most of their work "in-house." This will require a change in policy of a marked sort in their operations as well as in the detailed areas of research and development.

The CHAIRMAN. Now, largely in the past, it has been giving advice like, for example, aerodynamic designs of airplanes for civilian and military purposes.

If a bill along this line is enacted into law it puts the Agency in an entirely different position so far as primary objectives are concerned.

Do you think they are wedded so much to a path that they are capable of having the vision, the foresight, and the dynamic spirit to adjust themselves or whether we should create an entirely new agency?

Dr. WHIPPLE. I cannot answer that in a "Yes" or "No" fashion. I must say that they have done very fine work in the past and I think that a very heavy reshuffling would be necessary probably but it seems possible to me that they could indeed turn over a new leaf and attack this new problem effectively because there are some extremely competent people there.

The CHAIRMAN. Go ahead, Dr. Whipple.

Dr. WHIPPLE. I want to go on with a few comments about the bill. With regard to the 17-man board, I feel that this organization should have a very strong Director and that he should be given enough power so that he can act promptly and effectively.

It would seem to me that the 17-man board has in this bill enough power that if it felt necessary to provide the Director with more immediate assistant or he felt the need of having more opinion, they could have an executive group full time and they could appoint a great many panels and advisory groups to help out.

My own impression is that the 17-man Board is rather important because you can get from it representation in quite a number of areas in the Government, in the educational field, and in industry, so as to obtain a broader point of view in forming fundamental policy.

It would seem to me that the bill is broad enough to enable them to operate respectively by working out their own details themselves.

The CHAIRMAN. You are in some disagreement with Dr. Hagen.

Dr. WHIPPLE. I think a bit. I think this problem he brings up is important. They could have a small working group in the council or in the executive committee that was full time and carry out the functions that he had in mind.

But this is a matter of detail. The important point to me is that the Director be a man of extremely great ability and that he be given enough power to carry out this project effectively.

The CHAIRMAN. What do you think of a commission form of agency?

Dr. WHIPPLE. I do not have strong feelings on this one way or the other. It seems to me that the proposed system has a little more flexibility in it because the 17-man council could then set up its own organization to take care of whatever problems come up for decision.

The CHAIRMAN. Supposing one man is wrong?

Dr. WHIPPLE. You mean the Director?

The CHAIRMAN. Yes.

Dr. WHIPPLE. Then they should be able to fire him.

The CHAIRMAN. Don't you think a limited collective viewpoint is much better than an individual viewpoint? I am not talking about large numbers now. I am talking about a commission of five.

Dr. WHIPPLE. I would not be able to answer that with complete confidence. I feel that they could, within the powers given them here, set up a smaller group if they wanted to carry out this function and still have the broad representation of policy that a 17-man board would give, and which would not be given by a 3- or 5-man commission.

That is my point of view on that. Now, I feel it is very important that the salary level be adequate so that the scientists in the Astronautics Agency can be gotten on a competitive basis with industry and with other possibilities for them.

The CHAIRMAN. There is no difficulty, so far as I am concerned, with the provision of the bill, but when you allow this new Agency to appoint without regard to the Classification Act, then you have to consider other scientists employed elsewhere in the other activities who are bound by the Classification Act.

You can see the relative situation there. Then, when we come to that, this committee probably would not have jurisdiction over the

broad question. We would be clashing with the jurisdiction of the Committee on Post Office and Civil Service. That calls for no comment on your part; that is our headache. But I call it to your attention to show that, while I, personally, agree with the provisions of this, again, what about Dr. von Braun and his scientists, the scientists associated with him, Dr. Hagen, where they are subject to the Classification Act?

Are you under the Classification Act?

Dr. WHIPPLE. The policy is that we shall follow the Classification Act, which we do, so we are handicapped in the same way.

The CHAIRMAN. How would you feel if they found in this new Agency they could pay their scientists higher salaries than you can pay yours?

Dr. WHIPPLE. I would advise my scientists to get a job in this new Agency.

The CHAIRMAN. In other words, it would not be a very happy situation for you.

Dr. WHIPPLE. No, but I think, if this were done, it would be a first step which would lead to a correction, which I think is an error in policy.

The CHAIRMAN. There is something to that. In other words, you feel if it were put in this bill it would be the impetus for the others to be extended?

Dr. WHIPPLE. Yes.

The CHAIRMAN. Well, there is a thought in that.

Dr. WHIPPLE. If it is not done, I fear there will be a continuance of the present tendency, of loss of some scientists to the Government, both in the military and in the departments.

Mr. McDONOUGH. Mr. Chairman, I have a question there. For the number of scientists that we have in government now, astronautics astrophysical, and in space exploration, how do they compare with the same group outside of government in private industry right now?

Dr. WHIPPLE. Must I answer that question? I would like to be excused on the grounds——

Mr. McDONOUGH. Let me help your answer then. Do we have as many competent men in government service in these categories of the higher sciences as there are at the present time in private industry?

Dr. WHIPPLE. Would you excuse me if I answer that in a slightly different way, that if there were not this differential in salary you would have more scientists and more competent scientists in the Government than you have today.

Mr. McDONOUGH. Then they are available at the present time?

Dr. WHIPPLE. Yes.

Mr. McDONOUGH. They are available?

Dr. WHIPPLE. They are, a limited number, but this would also draw out more young men into science than are going into science today, because the salary considerations are a major factor in career decisions among young men. This is very vital for the future.

I had not intended to expand on this point, but it is quite clear that the Russian educational system is training more scientists, more engineers, more technical people than we are training, by a factor of 2, and is doing that by making the incentives high.

This is one way in which we can start this ball rolling here. I think that is one of the most vital points in our long-range national security, the drawing of able youngsters into science.

The CHAIRMAN. Have you finished your statement, Doctor?

Dr. WHIPPLE. I think that is adequate.

The CHAIRMAN. Mr. O'Brien?

Mr. O'BRIEN. In the interest of time, I have no questions.

The CHAIRMAN. Mr. Metcalf?

Mr. METCALF. I reserve my time.

The CHAIRMAN. Mr. Natcher?

Mr. NATCHER. No questions, Mr. Chairman.

The CHAIRMAN. Mr. Sisk?

Mr. SISK. I am going to ask the doctor one question. Will you elaborate on the discussion you heard this morning with reference to the menace of the satellites in space or an unusual number of satellites?

Dr. WHIPPLE. May I take 1 minute to answer that? I believe this morning that Dr. Hagen was referring more to the confusion in the radio broadcasting of many satellites on the same frequency, and I consider the chance for collision negligible.

I think the tracking problem, if anything, will be made better by having more objects to observe, because there is nothing like the boredom of operating these tracking systems with nothing to track. If there are more objects there, I think you will find your crews more alert.

The danger of satellites falling on people and property is so small, at least compared with the natural hazards of meteorites, that the problem will never become a serious one. That is my answer, but I will be glad to elaborate.

For geodetic research, to measure the shape and size of the earth and the precise separation of the continents and their geodetic networks, long-lived satellites are necessary. Otherwise, the rapid orbit changes from high atmospheric drag reduce the accuracy of the results. Orbits with their planes at various inclinations to the earth's Equator are also desirable for this research. Hence, I hope that a good number of long-lived satellites will be launched. From the tracking point of view, a large number (100?) satellites could be followed at one time without confusion, although the cost of the operation would be appreciable.

To destroy a satellite, other than by its own internal explosive, would probably be more explosive than launching it. I do not view with alarm a large increase in the number of artificial earth satellites.

The CHAIRMAN. Doctor, will you put into the record some of the problems of the classification of information that you referred to?

Dr. WHIPPLE. Yes, I shall do that.

(Material referred to follows:)

ATTACHMENT A

ON THE SECURITY CLASSIFICATION OF UPPER ATMOSPHERIC TECHNIQUES AND DATA

(By Fred L. Whipple, Harvard College Observatory)

(Prepared for the Research and Development Board in December 1952)

This discussion is divided into three sections: the first involves the losses to scientific research by security classification; the second the transition steps from basic scientific research to military instruments, and the third, the specific problem of classification of upper atmosphere techniques and data

A. *The loss to scientific progress resulting from security classification*

Science can progress rapidly only through the exchange of ideas, techniques, and data. The detailed manner in which security classification impedes free exchange and imperils the progress of basic science deserves some analysis. Let us first note the character of security classification as stated by regulations of one of the military services:

"No person is entitled solely by virtue of his grade or position to knowledge or possession of classified material. Such material will be entrusted only to those individuals whose official military or other governmental duties require such knowledge or possession. This principle applies equally to command control over the dissemination or distribution of classified matter as well as to individual discussions."

These regulations are obviously well-suited for the proper operation of a military organization whose plans or knowledge must be kept from the hands of the enemy. Such restrictions on the transfer of scientific knowledge, techniques, or data, however, are stifling to scientific research as follows: (1) It is eminently impossible for the person in charge of classified information to know specifically what scientific knowledge may be of value to each individual scientist; (2) it is not generally advisable to give each scientist free access to all classified material; (3) to give scientific information a different type of security classification than operational or strategic military information would probably be also impractical.

Hence, the scientist, if he is to learn the activities in other fields of science within classified areas, must, by unspecified means, learn of the existence of such activity, justify in detail his need to know about it, obtain clearance to learn about it, and finally, in many cases, make a journey to attain his goal. Only in the most vital circumstances can he expend all this effort to become better informed.

The losses to the scientist's individual progress and to the general progress of science occur, then, in at least the following ways:

1. By not being aware of the efforts by others, the scientist fails to contact able men who might give him specific assistance in his own problems.
2. The scientist may waste time solving problems that have already been solved, or proved unsoluble. Such unnecessarily wasted effort is devastating to the creative urge.
3. The scientists may lose the inspiration normally attained through broad contact with other scientists in widely diversified fields.
4. The scientist fails to gain new ideas by reading the general scientific literature, particularly in fields somewhat away from his own endeavor. Hence, the cross-fertilization obtained by applying techniques in one area of research into another area is greatly hampered.
5. The scientist tends to concentrate on a narrower field of endeavor and loses breadth of view.
6. Lack of broad contacts makes it much more difficult for the scientist to obtain a quick check on the validity of a new idea or technique. Since only a small percent of new ideas turn out to be of value, he will tend to get into the habit of discarding those new ideas that cannot be checked within his narrow range of information, or worse, of not seeking new ideas.
7. The lack of criticism by others in his subject, and the lack of immediate or possibly even ultimate criticism of his efforts, not only hampers the scientist in obtaining the correct or inspired scientific results, but also leads him to an attitude of less self-criticism and less scientific rigor. There can be no doubt that sometimes the cover of security classification is used to hide inferior scientific contributions.
8. The training of new scientists as graduate students is seriously impaired by security classification.
9. The handling of classified material and the maintenance of security wastes the scientist's time, consumes his energy, and creates nervous tension. This is particularly true for the scientist whose institution does not accept classified contracts or who must, for other reasons, work in relative isolation.
10. The nuisance of security checks on open publication and the complications of classified publications reduce the outflow of a scientist's published contributions.
11. Classified scientific material does not exist for the many scientists who do not work on Government contracts.

Thus, the effects of security classification are to dull scientific initiative and inspiration, narrow the field of an individual's research, reduce both the quantity and quality of his work, and impede and stifle progress in new or borderline fields of research. For these reasons, many of the most able scientists will not enter the field of classified research except in the case of national emergency.

The unhappy effects of security classification can, to a certain measure and in certain situations, be alleviated by the establishment of large research organizations in which the basic scientific research activities are not compartmentalized. Thus, a relatively free scientific exchange can be established among a rather large number of workers. Scientists in the smaller, and particularly borderline fields still suffer severe handicaps even under these most idealized conditions of research under security classification.

There appears to be no way in which security classification increases the quantity, quality, or breadth of basic research and a large number of ways in which it retards, inhibits, or halts scientific research.

B. Security classification in basic research and the transition to the development of military instruments

Since it is obvious that a few basic researches may, by their own nature, be of immediate value to the enemy, a practical balance must be maintained between the losses to research by security classification, and the gains obtained by preventing the enemy from access to the results or from a knowledge of the goal of the research.

In reaching the optimum compromises, the following points are of prime importance:

1. Security classification of scientific information imposes handicaps on ourselves as well as upon the potential enemy.

2. Security classification is justified only when the loss imposed upon the enemy appears to be greater than the loss imposed upon ourselves.

3 Classification of basic research will normally only delay the enemy, not prevent him from eventually discovering the basic facts. Thus, our scientific strength lies in progress rather than in preservation of our present knowledge.

4. Basic scientific knowledge is rarely, if ever, a defense weapon in itself. The road from the initial concept to a finished weapon is long and often uncharted.

Since scientific data and theory are the very building stones of technological progress, security restrictions at the basic research level will have the greatest effect in hampering our own progress. Such restrictions will not have a corresponding effect on the enemy, because he will certainly have knowledge of the same general kind, though perhaps not as complete or as accurate.

As the concept of a military instrument develops more and more toward its practical form, the technological development becomes more and more specialized, and the losses to the progress by security classification become less and less important. At the same time, the details of the design and probable performance become more and more valuable to a potential enemy. Probably, in most cases, security classification can best be imposed at the time when the concept is clearly enunciated as a potential tool of war and when a definite decision has been reached to attempt to develop the concept into a military tool. Classification of the research prior to the specific concept may indeed protect a single development more fully than classification at a somewhat later stage, but will delay or prevent the discovery of new concepts which may be even more valuable.

C. The specific problem of classification for upper atmospheric techniques and data

The chief arguments given for the classification of geophysical data are:

1. An enemy might use the data directly in the design or operation of some military instrument.

2. The data may reveal the performance of the vehicle used in obtaining it.

3. The data cost money, and therefore should not be given away.

4 The instrumentation for the research may be useful to the enemy.

In answer to the first argument, we note that an enemy who develops an instrument or system for high-altitude operation must have some data on the upper atmosphere to begin with and can readily obtain data of a specific nature from the instrument itself. Providing him with basic data concerning the upper atmosphere will add little to his already available knowledge and will be of no assistance whatsoever in the much more difficult problems of design and control.

Performance data of high-altitude vehicles, except for altitudes obtained, are rarely, if ever, necessary parts of reports concerning upper atmospheric research. In the upper atmospheric research so far conducted, the performances of the vehicles are so little above those of the German V-2 rocket of World II that the performance levels provide no additional information to a potential enemy. If there should be an opportunity for using a vehicle of much greater performance for basic high-atmospheric research but one that would require the classification of the results, then this panel is of the opinion that scientific progress would be more impeded by the classification than it would be by the lack of availability of the vehicle. Furthermore, it may be remarked that the scientists who are actually involved in the rocket soundings are fully responsible for maintaining the security of the vehicle's construction and operation under present regulations.

The fact that basic research in the upper atmosphere is expensive has no bearing upon the question of security classification. The chief result of imposing security restrictions would be to give us less return on an expensive investment.

The techniques used in upper-atmospheric research are adaptations of well-known principles in physics, and, in most cases, have no value except for the purpose for which they were designed. The communication devices and position-measuring devices used in upper-atmospheric research are largely classified and may well remain so. Their details are of no more significance in the description of the scientific results than is the design of the rocket motors used to propel the high-altitude vehicles.

The study of the upper atmosphere still remains essentially a virgin field of research. We now know the basic physical properties of the upper atmosphere, such as temperature, pressure, density, and composition, to a considerable height above New Mexico. We have very little information upon the general circulation and turbulence in the upper atmosphere. We have only preliminary indications of the dependence of these upper-atmospheric properties upon geographical position, season, or solar activity. Not even the vaguest suggestion of a comprehensive theory embracing the physical properties of the upper atmosphere in their relationships with the many phenomena of the upper atmosphere has been suggested. Type of phenomena to be interrelated, theoretically, include ionospheric phenomena, radio fadeouts, terrestrial magnetic activity, meteor phenomena, night-sky radiations, the anomalous propagation of sound, absorption of solar radiation in the upper atmosphere, disassociation, ionization, recombination, ion attachment, noctilucent clouds, and others.

In the basic research involving the theoretical integration of these many upper-atmospheric phenomena, we have received in the past enormous assistance from European scientists and scientists from other parts of the world. The problems to be solved are many, varied in character, and of extreme potential value in future high-altitude warfare. The imposition of security classification upon data obtained in our upper-atmospheric research would exclude most of our foreign colleagues who are extremely valuable to us in this research, would drive out of this field of endeavor a great many American scientists, and would greatly reduce the progress in this new field of research. Several important research organizations do not accept classified Government contracts, so that classification would automatically eliminate an appreciable fraction of the present research activity on the upper atmosphere.

The Geophysical Panel on the Atmosphere is of the opinion that the imposition of security classification on upper-atmospheric results and techniques would introduce far greater losses to our national-defense program than the minimal loss that might be so imposed upon a potential enemy. It is believed that research scientists, themselves, can be trusted to recognized and safeguard, by proper classification, such discoveries as would be of clear and immediate value to the potential enemies of the United States, if publicly revealed.

The fact that most upper-atmospheric research is supported by agencies of the Government cannot be regarded as a sufficient basis for automatic security classification of the results. The act of Congress establishing the National Science Foundation can be sighted as an explicit expression of public policy to the contrary.

The CHAIRMAN. And your views on the background of NACA and the need for high-level status?

(Material referred to follows:)

With regard to the NACA, there seem to be three areas in which rather drastic changes will be required in their operation. One I have already discussed, a required change in policy to increase markedly the percentage of contractual research and development that is necessary if our overall facilities and personnel in space research are to be used effectively. A second point concerns the nature of their research and developmental work. So far, following their assigned task, they have concentrated almost entirely upon problems of aeronautics. They have, indeed, shown some foresight in work on space sciences, but the percentage of their effort in this direction, I believe, is relatively small. I would expect, if the National Astronautics Act is consummated, that their in-house work on space sciences would be comparable to or greater than their present aeronautical work and that their total operation would be increased in scope by a factor of several times. This change in emphasis is not only an organizational and policy problem, but a real problem of finding the proper manpower for their in-house work and their administration of contractural work.

In the third problem area, I am not so well informed, but believe that the question revolves around the nature of NACA's present task, particularly its relationship to the air arms of the Defense Department and to the aviation industry. I gather that much of their high-priority work concerns troubleshooting of new equipment for the air services and, also, a considerable amount of development of new, required equipment If my hopes for the National Astronautics Agency are well founded, the duties would revolve much more on the basic scientific problems in space, that is, basic research, with a weaker role in development than they presently have in the field of aeronautics. This change of emphasis with regard to their point of view may, perhaps, be the most difficult of the problems for them to solve

Do you think that the IGY should be extended?

Dr. WHIPPLE. I feel that this National Astronautics Agency can indeed cover many of the functions of the IGY, and also, I feel that the National Science Foundation in its now, I hope, expanded program, can also cover some of the needs.

I feel that the IGY had the great benefit of arousing international interest to a high pitch for a short period of time, which is extremely valuable with regard to the programs that involve quantities that need to be observed on a worldwide basis. It would be impossible to sustain that high pitch over a long period of time.

Therefore, it seems to me that some of the research we are doing in the IGY should be continued by funds from the National Science Foundation and in the space studies by our National Astronautics Agency.

The CHAIRMAN. Mr. McDonough?

Mr. McDONOUGH. I do not want to take up too much time; I realize it is late.

In reference to this possibility of collision of satellites it is within the orbits as we now have them in space that you are speaking about; is it not?

Dr. WHIPPLE. Yes.

Mr. McDONOUGH. If we shot a satellite to a point beyond the present orbits, would it continue to orbit the earth if it went out 10,000 miles?

Dr. WHIPPLE. Yes; in fact, out to 250,000 miles, until it might encounter the moon and be destroyed in that fashion or be knocked out of the system.

Mr. McDONOUGH. What is the possibility of comets in irregular orbits that we know about colliding with a satellite?

Dr. WHIPPLE. No comet is known with certainty to have come within the moon's distance; so the chances are extremely small.

Mr. McDONOUGH. What is the orbit of Halley's Comet?

Dr. WHIPPLE. That has about a 75-year period. The minimum solar distance is somewhat smaller than the earth's distance from the sun. So that it comes inside the earth's orbit but not particularly close to the earth.

Mr. McDONOUGH. Is there any boundary line to this space as we know it?

Dr. WHIPPLE. That is an extremely difficult question. The atmosphere becomes less and less dense as one goes farther and farther out in space, but starting in the other direction we know that there is an appreciable quantity of matter in space, a minimum of 100 hydrogen atoms per cubic centimeter. Thus where the atmosphere stops and interplanetary space begins is very difficult to define.

The only measurement that I have heard about that might give you a definition is the distance to which the earth's magnetic field seems to control matter. The material appears to rotate more or less with the earth to about 50,000 miles, a very rough value but perhaps the right order of magnitude.

Mr. McDONOUGH. That is all, Mr. Chairman.

The CHAIRMAN. Mr. Fulton?

Mr. FULTON. I have no questions, but would you put in the record regarding the cooperation of yourself and the Astrophysical Laboratory, your institution in Cambridge, in the IGY so that we would have a pattern for that in the record?

Also I would like for the record any kind of contract or agreement you have with the National Science Foundation, plus the overall master agreement for the IGY. I would like their overall type agreement that set up the IGY.

Dr. WHIPPLE. With regard to the current cooperation of the Smithsonian Astrophysical Observatory with the efforts of the International Geophysical Year, I have earlier in this testimony outlined the nature of the satellite-tracking problem that we contracted to execute. It is limited to optical observations of artificial earth satellites and we have included visual type observations and photographic observations with precision cameras at 12 stations over the world. The contractual arrangements and various legal aspects of our effort are attached.

(Sample of letters of grant follows; other data is on file with the committee.)

NATIONAL SCIENCE FOUNDATION

OFFICE OF THE DIRECTOR

Washington 25, D. C.

JUNE 13, 1956
Grant No. Y/30.5/145

Dr. LEONARD CARMICHAEL,
Secretary, Smithsonian Institution,
Washington, D. C.

DEAR DR. CARMICHAEL: I am pleased to inform you that the sum of $125,000 is hereby granted by the National Science Foundation to the Smithsonian Institution, for "Initiation of optical tracking system for the International Geophysical Year earth satellite program," under the direction of Fred L. Whipple, Astrophysical Observatory. This grant will be paid on or about 2 weeks from the date of this letter, in full.

It is a condition of this grant that it may be revoked in whole or in part by the Foundation after consultation with the principal investigator and the grantee except that a revocation shall not affect any commitment which, in the judgment of the Foundation and the grantee, had become firm prior to the effective date of the revocation; and that funds not committed by the grantee prior

to the conclusion of the work contemplated under this grant shall be returned to the Foundation.

It is a further condition of this grant that disposition of domestic patent and other rights in any inventions or discoveries made or conceived during performance under this grant shall be the responsibility of the grantee; that disposition of foreign patent and other rights to any such invention or discovery shall be determined by the United States Government; that the grantee shall give the Foundation reasonable notice of application by the grantee or other person or institution for a foreign or domestic patent on any such invention or discovery; and, that upon issue of a domestic patent on any such invention or discovery, the patentee shall grant the Government an irrevocable, royalty-free, nonexclusive license for use of such invention or discovery for governmental purposes.

It is also a condition of this grant that title to all equipments procured with these funds shall vest in the grantee, provided, however, that such equipments must be used in accordance with approved plans for the forthcoming International Geophysical Year program, and, provided further, that following completion of the International Geophysical Year program, final disposition of these equipments shall be determined by the Foundation after consultation with the grantee.

The Foundation desires that this grant be administered in general accordance with the Foundation's policies for research grants, insofar as applicable thereto, as stated in "Grants for scientific research," April 1955; in accordance with "Reporting requirements for grants made in support of the International Geophysical Year," and, in conformity with other understandings reached between the Foundation and the grantee relating to this grant.

Please acknowledge receipt at your earliest convenience.

Sincerely yours,

C. E. SUNDERLIN, *Acting Director.*

SECTION A

APPLICATION FOR RESEARCH PROJECT FOR THE U. S. INTERNATIONAL GEOPHYSICAL YEAR PROGRAM

If approved, Smithsonian Institution will accept responsibility for administering a National Science Foundation grant for the USNC-IGY project described in the attached "Summary USNC-IGY Research Project Budget Estimates" which represents the present estimate of funds required to discharge the responsibility and the enclosed "Information on Research Project" which provides details of the proposed research plan and other pertinent data.

Title of Project: Initiation of Optical Tracking System
IGY Project Number: 30.5
Total Amount of Project: $125,000.00
Name and Address of Institution: Smithsonian Institution, 10th & Independence Avenue, NW., Washington 25, D. C.
Name, Title and Personal Signature of Project Director: Dr. Fred L. Whipple, Director, Smithsonian Astrophysical Observatory
Name, Title and Signature of Official Authorized to Sign for Institution: Dr. Leonard Carmichael, Secretary, Smithsonian Institution

Date: Jan. 26, 1957

SECTION B

INFORMATION ON RESEARCH PROJECT

This information should be prepared in narrative style, following the outline set forth below. A copy of this information should be attached to each of the six copies of this form being submitted to the U. S. National Committee.

1. *Project Information:*
   - 1.1 *Project Title:*
   - 1.2 *IGY Project Number:*
   - 1.3 *Name and Business Address of Individual to be Contacted for Detailed Project Information:*
   - 1.4 *Project Description:*
     - 1.4.1 *Describe plan of operation:*
       - (a) *Preliminary work:* List equipment to be built or procured; facilities to be procured and erected; explain plans for personnel acquisition and training; shipping plans (indicate where plans are uncertain because of unsolved problems); give time schedule for this work preparatory to commencing measurements July 1, 1957.

(b) *Measurement program:* Give location of measurement stations; describe facilities, equipment, other material, etc., which will be contributed at no cost to the project; describe briefly method and objectives of measurements; indicate plans and estimated schedule for closing out measurement station after December 31, 1958.

(c) *Data reduction and publication (only for data reduction centers):* Indicate extent to which you expect to participate in this part of IGY program; describe briefly any special techniques planned for data handling and any unsolved problems; indicate number of personnel and type (e. g., professionals, technicians, statistical clerks, etc) required; state where reduction work will be done; list anticipated donated facilities, space, personnel, etc.; estimate time required for data reduction and for publication.

2. *Related Work:*

2.1 Describe briefly prior history of your institution in this field.

2.2 Describe similar work at your institution currently under way; indicate plans for integrating this work with the IGY program; indicate, if possible, source of funds for this collateral work.

3 *Biographical Information*—Provide the following biographical information for the principal project director and other senior project investigators:

3.1 *Current Position* (give title and describe briefly)

3.2 *Prior Experience* (give title of and describe very briefly each principal position)

3.3 *Degrees Held and Institutions Conferring*

3.4 *Major Publications*

3.5 *Professional Affiliations and Honors Awarded in Field of Specialty*

Section "b" project 30.5

1. *Project Information*

1.1 Project Title: "Initiation of Optical Tracking System"

1.2 I. G. Y. Project Number: 30 5

1.3 Name and business address of individual to be contacted for detailed project information: Dr. Fred L. Whipple, Smithsonian Astrophysical Observatory, 60 Garden Street, Cambridge, Mass.

1.4 *Project Description*

1.4.1 (a) (b) and (c)

This project is a continuation of the preliminary phases as commenced under Project 30.3 and includes the development and emergency partial purchasing of and contracting for telescope cameras, parts, glass dishes, back-up plates, and other special equipment, and additional research and designing work, including developmental work for image-tube presentation prototype.

2. *Related Work-*

2.1 The solar radiation studies of the Smithsonian Institution in the astrophysical field have been publicized all over the world for a period of sixty years. It is felt that further comment here would be superfluous.

3. Biographical information: (See sheets submitted separately)

SECTION C

SUMMARY USNO-IGY RESEARCH PROJECT BUDGET ESTIMATES

(Provide complete detail for each indicated fiscal period. Specify dates by which funds for equipment and supplies must be received, and, for fiscal year 1956, dates and purposes for which other types of funds are required. If funds have already been received, identify in first column under appropriate budgetary items and include details. *Please submit on separate sheets six copies of budget statements, following this same form, for each station which you plan to install and/or operate.*)

	Through June 30, 1956	July 1, 1956 to June 30, 1957	July 1, 1957 to June 30, 1958	July 1, 1958 to June 30, 1959	Total
1. *Personal Services* (Indicate types and numbers of personnel, annual salary rates, percent of time to be spent on project Include separately a line item for retirement, social security, etc.); None; services of the Director (Whipple) and Associate Director (Hynek) are paid from regular Smithsonian Institution funds.					
2. *Travel* (Indicate nature and applicability): None					
3. *Shipping and transportation* (Specify) None					
4 *Communication*: None					
5 *Printing and Reproduction* (Indicate nature) None					
6 *Expendable Equipment and Supplies* (Indicate in general terms the types of equipment and supplies required)					
Power supply system for crystal clocks (batteries)		$2,396			
Optical glass and design of smaller items		5,000			
7. *Equipment (Permanent)* (Itemize)					
Procurement of 32 units of external glass discs for satellite tracking cameras at $1,822 each (Fish-Schurman Corporation)		58,304			
Procurement of back plates for satellite tracking cameras (estimated)		14,000			
1 clock recording mechanism and components (pulse gates)		5,000			
8. *Other* (Specify)					
(a) Optical design to optimize Schmidt optics		12,000			
(b) Crystal clock presentation system prototype		2,000			
(c) Development of contingency type contract for image-tube presentation prototype		10,000			
9. *Total Direct Costs*		108,700			
10. *Allowance for Indirect Costs* (only if applicable, and not to exceed 15 percent of total direct costs) Computed at 15%		16,300			
11 *Subtotals*					
12 *Data Reduction and Publication* (preliminary estimate; include indirect costs, if applicable)	xxx	xxx			
13. *Grand Total*		$125,000			

In summary, the United States National Committee of the International Geophysical Year under the auspices of the National Academy of Sciences recommended to the National Science Foundation that we be awarded a grant for the execution of this program through the period of the International Geophysical Year and extending on for 6 months beyond it to June 30, 1959. We are extremely attentive to recommendations by the National Committee of the IGY through their technical panel on the earth satellite program

and its working group on tracking and communication. The data and results that we obtain are transmitted to the National Committee in advance of publication and release.

Communication with IGY groups in other countries is conducted formally through the national committee but considerable scientific comunication is carried out on a scientist-to-scientist basis with those in other countries. The Moonwatch visual program has involved excellent cooperation with the IGY committees and individuals of a number of countries, excepting the U. S. S. R., which has its own Moonwatch program modeled almost precisely upon ours. Nine of our twelve tracking stations are on foreign soil and we have found admirable cooperation from the scientists of these countries. We feel that our programs are of real benefit in encouraging astronomy and science broadly in a number of these countries.

The satellite tracking program has involved a relatively large effort compared to the normal operations of the Smithsonian Astrophysical Observatory. A number of our scientists have been required to help out, on a temporary basis, with the unexpectedly rapid developments in the tracking program arising from the sputnik launchings in 1957. The program must continue for several years to complete the scientific research planned as the geodetic results cannot be obtained except from satellites of considerable lifetime observed for a period of a year or more.

Our specially developed cameras are the only ones in the world, to my knowledge, that have yet obtained precision photographs of the United States artificial satellites in orbit. I hope that these comments will clarify the questions with regard to our cooperation with the IGY.

The CHAIRMAN. Mr. Keating?

Mr. KEATING. I have nothing except to sound a warning about this telepuppet. As nearly as I can tell from what you say, it may have all of us out of a job.

Dr. WHIPPLE. There must be some person to manipulate each one of them. It will only put half of us out of a job.

The CHAIRMAN. Mr. Ford?

Mr. FORD. May I add a footnote to what Mr. Keating has said?

Some of us being put out of a job might please a lot of people.

In your comments earlier, Doctor, you mentioned that, in effect, this new agency should have what we consider to be no-year funds. Once the obligational authority is made available, it should be made available until obligated and expended.

That is done as far as the military is concerned in research and development and procurement and 1 or 2 other areas. Does your agency or subdivision have such authority now?

Dr. WHIPPLE. No.

Mr. FORD. Is that a handicap to the good prosecution of your program?

Dr. WHIPPLE. Yes, I should say so. In the present satellite-tracking program we have need of more men, for example, in celestial mechanics. There is a limited number of those people. We cannot give high-level people promise of a long, continuing position, or even 2 years for that matter. It makes it very difficult for us to import people who might be extremely valuable to us.

The CHAIRMAN. This bill provides for such an appropriation as I understand it.

Dr. WHIPPLE. I gather it does. I want to commend it in that respect.

Mr. FORD. Section 9 appears to give such authority, Mr. Chairman. I believe the wording is more or less identical with that in the various military appropriations. I think it is highly necessary.

The CHAIRMAN. Mr. Feldman?

Mr. FELDMAN. I have some questions that I would like to submit, Doctor. They will be in the record, and will you answer them when we send the record to you for editing?

Dr. WHIPPLE. Certainly.

(The questions referred to are as follows:)

1. Can you comment on the future prospects for astronomy once we are free of the distortions of the earth's atmosphere?
2. Is there any earthbound substitute for the clarity a satellite-mounted telescope might give us?
3. Can you explain what the Maser device can mean to astronomy?
4. Do you feel the hazards, such as meteorites of space will seriously limit the transport of men in space ships?
5. Could you comment on Dr. Hagen's point that identifying all satellites in the sky is important both to astronomers and to national defense?
6. Do you think meteorite erosion will end Vanguard's life sooner than 200 years?

(Material referred to follows:)

In answer to the second question there is no earth-bound substitute for the clarity that a satellite-mounted telescope might give us. There is, however, a possibility of obtaining the full resolving power of a telescope to separate the small details of planetary surfaces or of double stars in space by means of balloon-mounted telescopes. Some work has been done on this already and for a great many years it appears that the balloon-mounted telescope will probably be the least expensive means of obtaining the highest quality images of fine angular details in space. It is also possible that the balloon-mounted telescope will represent the least expensive method of studying space in the infrared, but not in the radio region, the ultraviolet, the X-ray region or the possible gamma-ray region.

The first question, "on the future prospects for astronomy once we are free of the distortions of the earth's atmosphere", can now be answered. Putting a telescope in space may revolutionize astronomy as much as the invention of the telescope itself. The radiations from stars and from interstellar matter range over some 60 octaves (each octave being a factor of 2) in the electromagnetic radiation spectrum. Optically we can observe only a little over one octave with about another octave available in certain regions of the infrared. In the radio frequencies a few octaves are available and are now used in radio astronomy. Nevertheless most of the radio range is reflected and absorbed by the earth's ionosphere and consequently cannot be used for studies of the universe. Hence the major advantage of a telescope mounted in space will be to study the universe in ultraviolet radiation, in X-ray radiation, possibly in gamma-ray radiation and finally in a very large section of the radio region. Furthermore in space we will be able to study directly the high velocity particles that are shot out from stars and possibly from great masses of gas in space. At greater and greater energies these particles link into what we know as cosmic rays and there again we can study the cosmic rays directly instead of a mixture of them coupled with a huge number of secondary effects arising from their striking the earth's upper atmosphere.

We do not yet understand how the violent storms on the sun arise, nor do we understand the real cause of the sun's corona. Solar emanations of both high-velocity particles and far ultraviolet radiations including X-rays affect the earth's magnetic field, the ionized layers of the atmosphere, (that make possible long-range radio communication) night sky light, the aurora borealis, and a number of manifestations on our planet. Observations from space will therefore give us information about the sun that will be directly applicable to an understanding of the sun and an understanding of these many related

phenomena on the earth including possibly the weather. We do not yet know for certain the origin of cosmic rays and I believe that observations of the solar universe and the interstellar gas from above the earth's atmosphere will be required to clarify this basic problem. The origin, birth and death of stars are all only incompletely understood and direct observations in these inaccessible radiation regions will give us clues that I believe will lead toward answers to these problems. Furthermore we have the major features of the universe at large, the great galaxies of stars, their structure, origin, and evolution, intensely hot regions in space whose origins in some cases are uncertain. Space research probably will lead to completely new concepts and possibly new physical laws when we study such major phenomena as the collision of external galaxies. Knowledge gained from outside the atmosphere should lead us far on the road to an understanding of the universe, or at least many more limitations on tenable theories for the origin of the universe.

The physical exploration of the moon will, I believe, provide us with a clear-cut understanding of the origin of the earth since the clues on the moon will be undisturbed as compared to those on the rapidly changing earth's surface. The very fundamental problem of life on other planets will be much clarified by the physical exploration of the nearby planets, Venus and Mars.

Without a long article on the subject this account gives some idea of our expectations for astronomy from a space station. Already we have seen from the cosmic ray measures of the American Explorers that surprises are in store for us in space. I am certain that the most valuable results will be those that are unexpected in character; and this applies not only to the nature of the universe but to the technological developments involved in space explorations.

The Maser device will increase the sensitivity of radio receivers by a large factor. This means in astronomy that radiotelescopes on the earth (or in space at the frequencies that do not penetrate the ionosphere) can be made many times more sensitive than those in common use today. This revolutionary device will, therefore, increase the value of radio measurements by a large factor and enable us to study sources of radiation that are weaker by this same factor. Thus the advantages in radio astronomy will be extremely great and we expect that new areas of study will be opened up by the "Maser."

With regard to the hazards of space, such as meteorites, I feel that they will increase somewhat the cost of space exploration, but will not seriously limit the transport of men in spaceships. In other words, the hazards of space can be determined with precision by means of unmanned space vehicles, so that design elements in actual manned space vehicles can reduce these hazards to minimum values compared to the major hazards of launching, maintaining a livable environment, and reentry. Because of the hazards, space vehicles may be heavier and provided with special devices which will increase the cost per pound of payload. But I do not see a real deterrent to manned space travel in the natural hazards that we can now anticipate in space.

With regard to question 5, I have already, in my testimony, reported on Dr. Hagen's point that identifying all satellites in the sky is important, both to astronomers and the national defense.

With regard to meteorite erosion, it is difficult to estimate just how vulnerable the Vanguard's satellite will be to this process. I estimate that in 200 years the erosion will not amount to much more than a thousandth of an inch, on the average, over the surface This should not be serious, but there is the real possibility that larger meteorites will strike a vulnerable connection wire or element in the satellite and thus end its usefulness. My very rough guess is that the chances of meteoritic collision ending the radio usefulness of the Vanguard satellite is more or less 50–50 in 100 years. The etching of the windows by meteoritic dust may reduce the efficiency of the solar batteries in a decade or so, but should not render them useless These guesses could easily be in error by a factor of more than 10.

The CHAIRMAN. Doctor, these tracking stations you refer to; will you go into more detail on them?

Dr. WHIPPLE. Yes. There are 12 of them located around the earth; for example, in the Northern Hemisphere—New Mexico, Florida, Spain, Iran, India, Japan, Hawaii, and Curacao; in the Southern Hemisphere—South Africa, Australia, and 2 in South America.

They have a novel and extremely difficult optical system in the tracking camera, so that we have, indeed, been able to photograph

both the Explorer I and Vanguard. The Explorer I, optically, is a 6-inch tube about 50 inches long, painted white, which we have been able to photograph at 700 miles' distance. Each station comprises, also, a precision clock, accurate to about a thousandth of a second, and the time is photographed on our film, along with the satellite photographs to be read to one ten-thousandth of a second.

The CHAIRMAN. Also, you made reference to the value that might flow in the future from the money spent that would redound to the peacetime advancement and so forth. Will you elaborate on that when you are editing your testimony?

Dr. WHIPPLE. Yes, sir. I have already mentioned the direct commercial values to the peacetime world of the meteorological advances that should be possible from artificial earth satellites and, also, the incidental development of remote-controlled "telepuppets" as a high probability. Almost every one of the technological requirements for space exploration can readily be shown to lead to practical everyday uses in our modern world.

There is no question in my mind that the developments in miniaturization required specifically for space science will in fact accelerate valuable applications in everyday life. Many of these developments will certainly be included in aircraft and, probably, in automobiles, as well as in household devices as the techniques of their manufacture become more developed. This will mean an increase in reliability, along with a great reduction in volume and power consumption for a multitude of such devices.

Developments in high-temperature-resistant materials for rocketry will certainly find applications throughout our industry where fuels, powers, and high temperatures are involved in practical applications.

The guidance and control requirements for space vehicles will certainly be of value in a multitude of practical instrumentation and manufacturing techniques.

The development of reliable controlled rockets and reentry techniques for manned space vehicles will almost inevitably lead to rocket-type vehicles for point-to-point rapid transportation on the earth. Hence, no point of the earth will be more than 2 hours away from any other point for actual travel. We have seen this type of development in the aircraft industry, and I have no question that it will occur in the rocketry industry.

The development of special fuels for rocket purposes will become applicable for peacetime uses. Particularly, a demand for lightweight, long-lived energy sources necessary for ordinary power requirements in space exploration will certainly be of great value in our everyday life. The impetus of the developments necessary for space exploration will greatly hasten the day when these compact, long-lived power sources will become available. We have already seen the impetus of the IGY satellite program in the development of the solar batteries.

In the biological areas, I am not particularly competent, but can readily see where a solution of basic problems in maintaining man in space may have application to everyday life, particularly to utilization of land areas that are now considered as waste for food consumption or for habitation. For example, hydroponic gardens, utilizing solar radiation and little power, must be studied extensively so that man may, possibly, survive indefinitely in spact without the need for an artificial power source. Developments along these lines could

easily find applications in utilizing desert areas for habitation and food supply.

The space program will almost certainly accelerate research in the biological effects of cosmic radiation and X-radiation and, also, in areas involving the effects of exhalation waste on human metabolism, not to mention psychological factors of isolation and the like.

I have not attempted to be complete in listing such byproducts of space exploration, but wish to indicate the nature of the progress that may be accelerated by such a program. Again, I reiterate the experience of the past when a new research area is opened; the greatest developments and the most important results obtained from the research are practically always the unexpected.

The CHAIRMAN. Any further questions? Doctor, we appreciate very much your appearance and, also, your patience. This is a very serious assignment which has been given to us. You can see, by the fact that we are working as late as we are, that the members of the committee are taking it very seriously. For myself, as chairman, and for the members of the committee, I express to you our sincere thanks.

Dr. WHIPPLE. It is a pleasure, indeed, sir.

The CHAIRMAN. The next witness is Dr. H. Guyford Stever, associate dean of engineering and Chairman of the National Advisory Committee on Aeronautics, Special Committee on Space Technology. We shall be very glad to hear from you, Doctor.

STATEMENT OF DR. H. GUYFORD STEVER,[11] ASSOCIATE DEAN OF ENGINEERING, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, CHAIRMAN, NATIONAL ADVISORY COMMITTEE ON AERONAUTICS, SPECIAL COMMITTEE ON SPACE TECHNOLOGY

Dr. STEVER. Thank you, sir. In the first place, may I make one correction in reference to your introduction of me, and I think you, Mr. Chairman, will appreciate it. I am the associate dean of engineering at the Massachusetts Institute of Technology.

The CHAIRMAN. That is correct. Pardon me for making that error, because we all know about the MIT, and I have a very friendly relationship with President Killian, and I met General McCormack and had lunch with him in Boston not long ago, Hal Weber, and others.

Dr. STEVER. Mr. Chairman, I have a few notes, but, for the sake of brevity, if I have your permission, I will not read them. I still would like to make a few of the points in my notes in a very brief manner. I would like, also, to introduce my notes into the record.

In the first place, it seems to me that the most important consideration we have as we lay out our Government's venture into space, as this committee is doing, is to recognize that this is an activity which will have a continued existence.

---

I think we have to realize that man's interest in this field goes back in time a lot farther than sputnik and existed long before our generation of science. In fact, man's interest in space goes back to some of the greatest minds centuries and centuries ago. For example, a member of a great senate long ago, Cicero, wrote an article on travel into space.

I would like to refer you to his Die Somnium Scipionis for some interesting thoughts. It is indeed a very long-term activity that we are pointing toward. I am pleased in noting in the questions of the committee that you are taking the long-term aspects of space technology very seriously.

I am concerned with the publicity that we in this field are getting; it pays much too much attention to the short-term aspects, for example, the spectacular shots of the first passenger in space, or the first instrument landing on the moon. The public may think that this is the only important aspect.

Actually, the phases of space technology that have paid off already are well known to you. In the military field there is an unquestioned payoff and most of us who know this field believe that the progress will continue for a long time.

Also, you have had distinguished scientists here who have given you their comments about the scientific benefits of a space program. However, if you go beyond the military and scientific fields, there are some other uses of space in which we have not done so well to date. For example, when the NACA Special Committee on Space Technology helds its first meetings, we found that most of the ideas that had been developed in this country pertained mainly to the military and scientific uses. Still, we see some unsupported engineering applications which can do us some good in our daily lives.

The communications relay stations and the weather prediction stations on satellites have already been mentioned in testimony to this committee. I think we should develop these much more rapidly. Of the hundreds of proposals that I know about in the space-flight field, a very large number of them are pointed toward short-term spectacular jobs such as sending some instruments to the moon, sending a man to the moon. Very few of them are pointed toward the long-term program which will result in good for mankind. I believe that we have to look at this unbalance very carefully. Certainly in the NACA Space Technology Committee activity with which I am associated, this will be one of our principal objectives.

Much has been said about putting man in space. I am referring here not to the short-range flights that have been mentioned by Dr. von Braun, but flights with a man in a satellite or a man in a moonship. It is my belief that we have a long way to go before we really are going to be able to accomplish this.

We have a lot of experiments to perform before we know whether it will be possible to get the man safely out and safely back. I say "whether it will be possible." In the long run, I am perfectly confident that it will be possible, but we have a lot to do before we can actually achieve it.

Also, as has been pointed out, we still have a question as to the reason for a man in space.

Let me talk a little bit about the kind of activity that I think has to go into a space program. In the first place, we have already started

some very good scientific experiments. You have heard this described in detail and I am confident that that part of it will proceed with good success.

This type of work is carried out by the scientific laboratories of the country; that is, Government laboratories and academic laboratories. A lot of its success, however, depends upon not only scientific achievement but engineering achievement in the devices which take the scientific instruments out into space.

This engineering achievement is also technical; many people call it scientific, but I think of it as an achievement of large engineering development laboratories within industry which are available to the Government.

There is another somewhat different technical activity which involves laboratory work, not on the scientific experiments and not on the vehicles themselves, but on the components which will eventually lead to a greater capability in space-flight vehicles in the future. I think, for example, of the sort of experiments that are being done in atomic energy for future propulsion, such as ion propulsion, nuclear propulsion, and possibly photon propulsion.

In any organization to handle the national space flight interests, scientific and engineering abilities must be tapped. Men with these different abilities are collected in a number of different places in this country, in Government, in industry, and in academic institutions.

I would like to state that I favor the organizational proposal which uses NACA as the nucleus of a new organization. I can make complimentary remarks about NACA because I have never actually worked for them. In fact, this space technology activity is the first activity of mine in which I have been an adviser to them. Still, I have recognized for some time that the NACA was a fine working group. They have already entered the space technology field; they have also worked in closely related aeronautical fields.

In the long run, there will be a continuous spectrum of science and engineering, starting covering low-speed flight in the lower atmosphere and continuing right up through higher and higher speeds to higher and higher altitudes.

One will not be able to distinguish where aeronautics cuts off and astronautics begins. I do not believe that responsibility can be divided early amongst two or more agencies.

I would like to see an organization which encompasses all the flight problems from zero altitude and zero speed up to, hopefully, an infinite altitude and infinite speed.

The CHAIRMAN. In practical effect, Doctor, will that not reside outside of the field of atomic energy? Is that not bound to be the practical result if an agency is established?

Dr. STEVER. If the Agency is set up according to this bill I believe that is correct.

The CHAIRMAN. In other words, we are projecting our minds and applying the law of natural consequence.

Dr. STEVER. There have been suggestions about an agency which deals with space only, and another agency which deals with atmospheric flight, in other words, the continuation of NACA. I do not believe that these subjects can be separated easily.

Mr. FULTON. I want to compliment you, first, for being the only scientist who has discussed this as a practical study, photon propul-

sion, and second, to compliment you on being the only scientist who has referred to an infinite speed which greatly exceeds the speed of light.

Dr. STEVER. Thank you. One other point I would like to make is that the military applications of space technology, the scientific applications, the engineering applications for nonmilitary purposes, all will use the same scientific and engineering background.

I think that the organization that is set up to handle space must have a capability of working with the military. NACA has already established very fine working relationships there. They also have the capability of working with the other organizations such as the National Science Foundation and the National Academy, which concentrate on the scientific side of these problems.

I think it is important, as you have indicated you will do in this bill, to establish a new agency based on NACA because, as I have already mentioned, the Agency must tap resources outside of Government. Industry and the academic institutions must be brought in. This must be done by contract and, by and large, the NACA has not had a contract program of the order of magnitude that I expect will be necessary here.

The CHAIRMAN. Doctor, I know the committee and I will appreciate it if you will carefully look over this bill and make suggestions where it can be strengthened along the line of divisibility. Not that they will recognize it right away, but the authority will be there.

Like yourself, I cannot see how you can divide this activity, this whole field. I can see immediately, starting out, the concentration on certain levels, but I do not see where there can be that divisibility and there must be the merging, the melding, and I will feel happy if the authority is in there for the future when that situation arises.

Dr. STEVER. I will certainly look at it from that point of view and make comments on it. I would like to make one other point, which is more general than space technology, but still it applies.

I believe it is important in the planning stage of this activity that we are now in to bring a large number of organizations in to think over the problems and to decide upon a program. I believe that the organization that is established must, however, after the program is selected and after the support is given, decentralize its authority and responsibility.

I think we are making a mistake in this country, as we elevate our science and our technology and our technical questions to higher and higher levels in Government, in bringing detailed direction to the highest levels.

I would hope that the higher levels of Government continue in the broad policymaking and the planning functions, but that authority and responsibility for doing the jobs must be passed down to the working technical level.

Somebody has mentioned the many levels of decision which Dr. Hagen had to go through. We can respond in our technical programs in this country much more rapidly than we have in the past provided we decentralize authority and responsibility after our major plans and programs have been made.

Mr. McDONOUGH. You mean have a freer hand?

Dr. STEVER. When the decision to go ahead with a project is given, I think the working level should have a free hand. The project leader should stand or fall on his accomplishments. In fact, I believe that

occasional failure because we picked the wrong man is far better than the delay we now get in all our projects by too detailed checking upon him.

I do not think that the project leader should have a free hand in the planning and the idea stage. At that time ideas must come from every echelon, high and low. From my own observation of the NACA leadership, I believe they appreciate this requirement of decentralized operation and centralized policy in getting a scientific or technical job done.

Mr. McDONOUGH. Do you think Russia has given that freedom to their scientists?

Dr. STEVER. I think they have a considerable element of the delegation of responsibility and authority at the same time. They also have one thing we do not have, which is a very effective way of punishing somebody if he does not come through.

Mr. McDONOUGH. He is free as long as he produces.

Dr. STEVER. That is right.

Mr. FULTON. For the record, may I say that Tupelov recommended your program to the Russian Government in 1928, which was then adopted, so there are now over 770 scientific institutes operating in the Soviet Union.

Dr. STEVER. Sir, that is a summary of my prepared remarks.

The CHAIRMAN. Mr. O'Brien?

Mr. O'BRIEN. I would like to ask one brief question, primarily because the Doctor emphasized MIT.

Do you think that we have, including some of the witnesses before this committee, overemphasized the weakness of our science posture in this country as compared with Russia? Are we as badly off in our schools?

You are from an institution which gets pretty much the cream of them. Are they still coming in? Is there an interest in science?

Dr. STEVER. Sir, I am very glad to be asked that question because I would like to go on record to say that I think we are far superior in our overall schooling system to Russia. I do think that Russia, with a very lopsided system, has concentrated on science and technology and there they are doing well.

I hope that we never create the Russian unbalance in our school system. I would point out, however, that science and engineering are subjects which change very rapidly, and it is very easy for a good schooling system like ours to get behind, especially at the lower grades. I am very pleased that the educational input from this so-called sputnik crisis resulted in an overhauling of that aspect of our education.

Mr. O'BRIEN. That leads to my second question.

I would hope that, too, but do you not think the very fact that we are in this space era now, whether we want it or not, is going to lead to a tremendous increase in the interest in science on the part of young people?

I have noticed right here in Congress, here is a group of pretty busy people. They have been sitting here morning and afternoon whenever they could and they are fascinated by the subject. I just wonder with all these tremendous possibilities that you and other witnesses have opened up—possibilities from a practical viewpoint, a job if you will, perhaps celestial mechanics—do you not think there will be a natural turning toward science and engineering by young people who will see the glamor and fascination of this new era?

Dr. STEVER. Yes, we have already noticed that.

The CHAIRMAN. We also have the job of accomplishing the future problem that faces us in preserving the fundamental ways of life we believe in; in other words, to have it serve us rather than master us, whatever the future might unfold. Is that right, Doctor?

Dr. STEVER. Yes, sir. I would say along that line that I do not want to be led into a space program or a schooling program by the Russians We have lots of good ideas of our own on both of these subjects. Now, we can be spurred on in our efforts by the Russians. We can be given a push to make sure that we go a little faster, but I do not believe that I would adopt the Russian approach either for our school system or for our space program.

We have some good long-term reasons for having our own space technology program independent of what the Russians are doing, and I have outlined them here. I think there is no question but what we are in some aspect of competition with Russia with respect to this, but I do not want to follow them.

I would make the same remarks with respect to our schooling system; I do not want to adopt the Russian schooling system. I would like to improve our own and not give up some of the things we want.

Mr. FULTON. For the future which has just been brought up, could you give us possible various industrial developments so we could insert them in the record? That is, new industries and new scientific practical application that you can see which would be of benefit to the economy in such space programs and space research?

Dr. STEVER. Yes, sir.

The CHAIRMAN. Mr. O'Brien?

Mr. O'BRIEN. Mr. Fulton has taken care of my final question. In connection with your reference to spectacular stunts, am I correct in assuming that you mean that eventually you will get to the moon but that we should not devote all our energies in getting to the moon, we should learn a great many things on our way to the moon?

Dr. STEVER. Yes, sir.

Now, can I make just one addition to that? I have seen many proposals which not only would take all the money we have for space technology but would take all the money we have for defense of the country, and most of them are for what I have called the spectacular type of flight.

We have a good deal of good, hard, engineering and scientific work to do and we can do it in a sound way and still reach these objectives. I think we have to concentrate on the right things.

Mr. O'BRIEN. Thank you very much, Doctor.

Dr. STEVER. Thank you, Mr. Chairman.

The CHAIRMAN. Mr. Metcalf or Mr. Natcher.

Mr. NATCHER. Doctor, as I understand, you are of the opinion that the two agencies should be patterned after the NACA but it should be on more of an expanded basis with certain contractual rights and other duties to perform which, of course, the NACA does not have.

What part, if any, should the military have in the new agency?

Dr. STEVER. Sir, in the first place, I think the agency should not be under the control of the military. Still, the new agency must have a very good working relationship with them.

Let me take one technical problem that is only touched upon occasionally. This is the area which we, in the NACA Space Technology

Committee, have referred to as surveillance. It involves tracking our own satellites which are friendly satellites, our own space vehicles, which are friendly, and into which we can put radio beacons, and so on; this technical problem of tracking friendly vehicles with beacons is not too difficult because it is a one-way transmission of energy. But if we are involved in the defense of our country there will be lots of vehicles, such as enemy satellites, which will be inert. We will not be able to track them by self-contained radios. We will have to use radar or other schemes. Immediately the surveillance problem of this space technology agency we are talking about gets linked to the surveillance problem which the military people have. So there must be a very close working relationship on surveillance.

A second area of overlap is in rocketry. It does not make sense for this country to develop different rocket motors which often are quite similar technically both for nonmilitary and military programs. There must be an exchange of equipment. I think this can be done on a relationship which is not a controlling relationship but a mutual-agreement relationship.

In the third place, the military organizations which will develop better ballistic missiles, military satellites, and so on, are going to depend on the same background science and technology as does the civilian space agency. Their technical interests then will overlap. The new agency can help the military a great deal by giving them information and new techniques. The relationship must be very close but I hope that it is not one of control.

Mr. NATCHER. Thank you, Doctor.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. Doctor, do you have any concern with reference to the littering up of space with too many satellites?

Dr. STEVER. I do not have a concern with respect to collision because it is already littered up with comets, asteroids, and meteors.

But I do have a concern with respect to the surveillance problem again. If we get too many vehicles out in space, pretty soon we will have such a very difficult job of keeping track of them and of distinguishing the ones we know cannot harm us from new ones that might be launched in a military venture against us.

I think if we have this space filled up there with lots of vehicles, a surprise attack by enemy ballistic missiles will be much easier to accomplish.

Mr. SISK. You think it then would enhance the possibility of a real surprise attack?

Dr. STEVER. Yes, sir.

In this respect I think we are more susceptible to surprise attack than the enemy because they would be the aggressor.

Mr. SISK. That is all.

The CHAIRMAN. Mr. McDonough.

Mr. MCDONOUGH. I appreciate your appearance here and the information you have given us, Dr. Stever.

Is not the development of rockets principally a Government function now because it is not a commercially feasible project for private industry?

Dr. STEVER. The larger rockets are very expensive to develop. So far, the Government, mostly the military, has been the only user and,

more pointedly, the scientists have taken advantage of military developments to accomplish some of their experiments.

There may be a time in the future when the development of rockets for nonmilitary purposes will become a sufficiently large business to become a profitable one by itself.

I would say this, however: I think that the rocket industry can get joint support from the military and the new agency and so will prove to be a profitable business venture.

Mr. McDonough. Well, in addition to weather reconnaissance, there is the communications advantage.

Dr. Stever. I am sorry, I must have missed the sense of your question.

You are now asking whether, in these scientific and engineering applications for nonmilitary uses, is there a big production volume that will prove profitable to industry.

Mr. McDonough. Yes.

Dr. Stever. I do not think that it is a volume business in the same way that the ballistic-missile business is. This is one of the aspects of nonmilitary space technology that is going to be very hard to get around. Until it becomes a volume business it will be difficult to get the developments we want unless we put Government money into it.

Mr. McDonough. If we had satellites in orbit and relay stations, we could speed up our communications system much more rapidly than we have now, worldwide?

Dr. Stever. Yes, sir.

Mr. McDonough. And we could also use the ballistic missile type for transmission of material from one part of the world. That is a practical thing as of today, is it not?

Dr. Stever. Well, it probably is not an economic thing because it is very difficult to have many materials that you will pay a lot for to transport that rapidly. That may not be true in the future.

Mr. McDonough. Thank you, Doctor.

Mr. O'Brien (presiding). Mr. Fulton.

Mr. Fulton. I have no questions but I would like to have the witness give his ideas on several statements for the record, if you will, please.

This committee needs advice on the programs for the Space Agency on the national space program. For example, first I would like to have your ideas on the surveillance and reconnaissance fields.

Second, on the policy that we should, as a Nation, follow on its security programs for the space age, and divide that security program in basic and applied sciences as well as the engineering fields.

Then I would like to have your ideas, too, on the governmental policy on patents, copyrights, trade secrets, and business property rights, including chemical formulas and mechanical procedures with regard to the space age.

Mr. Feldman. We will send the transcript to you so that will be all in the record.

Mr. Fulton. Then, because you are a young scientist who has made wonderful progress and is connected with a fine institution, MIT, I would like to have your ideas on how young people in this country can take part in these space programs. For example, all the young fellows and the teen-agers around our place, from 12 on, want to put some amateur rockets in the air, and they are not allowed to.

They are afraid they will get some on the roofs of some people and blow them apart.

Now, can we get a supervised national program going for rocket experiments for young people in grade and high schools as well as college levels?

Likewise, how would you recommend that we get a national program going for classes on space subjects in grade schools, high schools, and colleges to supplement current training?

Thank you very much.

Dr. STEVER. Thank you.

Mr. O'BRIEN. Mr. Feldman.

Mr. FELDMAN. Doctor, would you favor a strong provision in this law requiring a liaison with the military and a liaison with the Atomic Energy Commission?

Dr. STEVER. I do not know whether it is necessary to have it in the act. I do believe it is necessary to accomplish it, however, if the military and the nonmilitary programs in space are achieved efficiently.

Mr. FELDMAN. Such a provision is contained in the Atomic Energy Act and all the testimony we have indicates that it works very successfully. It is a directive, in other words.

Dr. STEVER. I do not think a directive is bad at all because it is an absolute necessity, I believe.

Mr. FELDMAN. Would you also favor having the head of this organization on a level equal to that of the Cabinet?

Dr. STEVER. Sir, I believe this is a growing activity.

I am perfectly confident we are not going to find this closing up because we cannot find more things to do in space technology.

I think it is going to be a mushrooming activity.

I would like to see the field established at this time to take account of a much more important role in the future activity of our Government. I feel it already has considerable importance, so I would answer the question affirmatively.

Mr. FELDMAN. I have no further questions.

Mr. FULTON. Is there room in outer space for politics?

Dr. STEVER. That is one of the questions I am going to stay away from. You must read Cicero on this.

Mr. FULTON. I have already written down to do it.

Mr. FELDMAN. I do have one more question, Doctor.

What would your reaction be to developing or providing for a central register of technical talent in this field?

Dr. STEVER. I would say that it might accomplish some things which are needed.

With respect to the leadership talent, it is already recognized. For example, you have a lot of them listed to testify to this committee. The leadership talent is recognized and I think if you take the sum knowledge of the military services, NACA, and so on, it is pretty well known which organizations have substantial technical talent. However, if there is to be, as a result of the formation of the new agency, a fair amount of shifting of talent from one group to the other, then it would be very valuable to have such a register.

Mr. FELDMAN. Would you also be in favor of including a provision calling for a joint congressional committee to which the agency would

respond such as we have in connection with the Atomic Energy Commission?

Dr. STEVER. On that question again, I cannot say that I am an expert but I do believe this: I believe very strongly that when matters of policy, major matters of policy, come up, we get a lot better result in the end if it has gone through our standard democratic procedures and is referred to the representatives of the people. In other words, I hope that something is set up by which the elected representatives of the people are in constant liaison, contact, with the space activity.

I hope we do not lose this contact.

Mr. FELDMAN. I have no further questions.

Mr. O'BRIEN. Any further questions?

Mr. SISK. Dr. Stever, I would like to have you make a statement in the record as to your position in regard to the security or the exchange of information on a worldwide basis or to what extent you feel classification of material may be necessary.

Mr. FULTON. I will join you on that question.

Mr. SISK. I will be interested in reading the record for your position on that.

Dr. STEVER. I certainly will do that.

(Material referred to follows:)

The data and other results of the scientific work which we do in space technology should be, by and large, given general circulation in the scientific journals of this country and throughout the world Of course, there will be some slight gain to our potential enemy from their having been given this data by us. But the amount of respect that we will get from the friendly peoples of the world, when they realize that we are primarily interested in space from a scientific and natural philosophy point of view, will more than outweigh these slight military advantages. Furthermore, our potential enemies will be forced into a poisition in which they will also reveal their accrual of data and knowledge.

It is certain that some of the rocket-vehicle techniques that we develop for our exploration of space, either by manned or instrument-carrying vehicles, will be of great use to the military in their applications of space technology. Clearly, we must be reasonable about keeping some matters which will give us a distinct military advantage secure from the potential enemy. I believe that the amount of information in this class will be limited.

The military security program in this country, with respect to technical data and knowhow, I believe, is overdone. In the first place, our security system is not very tight; most important leaks come, not from the activity of spies or traitors, but from the natural processes of democratic action in which agencies of Government, industry, and others release data in order to get support. I believe that many of the democratic processes of government could not be carried out as well if our security system were tighter. The security system that we do have tends to let loose the important facts and to keep the less important technical data secure not only from the enemy but also from some of our own scientists. I think it is overdone.

A security system soon develops other uses besides keeping important information from the enemy. It becomes a crutch on which we lean to cover up gaps in our own knowledge or to conceal some embarrassing facts. A person who is subject to a security system of this sort soon gets into the habit of classifying everything because it is so convenient to do so.

I believe we must carefully examine our space technology activity and select carefully the things which we must keep from the enemy and publish widely the rest

Mr. O'BRIEN. Doctor, the committee is very grateful to you. You have covered a wide range of subjects concisely and very well.

Dr. STEVER. Thank you, sir.

(Dr. Stever's prepared statement follows:)

STATEMENT BY DR. H. GUYFORD STEVER, ASSOCIATE DEAN OF ENGINEERING, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, AND CHAIRMAN, NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS SPECIAL COMMITTEE ON SPACE TECHNOLOGY

In laying the groundwork for our Government's major venture in astronautics and space exploration, as this Committee is helping to do, the most important consideration, I believe, is that this activity will be of long duration and of ever-growing importance. Man's interest in the physical universe outside his earth, and his desire to explore that universe, is very old and very intense. His capability to explore it physically and to send scientific apparatus well out into this universe is something which has been realized only in our generation. As this capability develops, I am sure his interest will grow even stronger. Because of all this, I believe we must plan an organization capable of giving us strength over many years, an organization capable of marked growth. I believe that we must not be overly influenced by the desire to do something spectacular on a short-term basis; we must lay a strong foundation both organizationally and technically.

The phases of astronautics and space exploration activities which have clearly yielded returns are the scientific and military phases. You are well aware of the rapid exploitation of these techniques in military technology, so I will not detail them. I am confident that this military exploitation should and will continue, and that from it not only will come increased military strength but also knowledge, techniques, and equipment which can be used for our nonmilitary space activity. Our nonmilitary organization and program, though not controlled by the military, should be in close contact with it for mutual exchange of ideas, data, techniques, equipment, and bases.

With respect to scientific research, both to learn more about the physical universe outside the confines of the earth, and to use this cosmic laboratory for a better understanding of the physical laws which govern physical processes here on the earth as well, these rocket techniques are unfolding a wealth of interesting possibilities. This scientific research, already well started, should grow apace.

What of the other nonmilitary aspects of astronautics and space exploration? Already, we see some simple engineering ventures of practical use involving communication relay stations and weather observation stations on satellites. Also, physical exploration of the solar system is something to begin in a limited way. There are some other long-term and highly imaginative accomplishments of space flight which are speculated upon by some. Personally, I believe that there will evolve many important uses of these techniques of space flight as we develop our capabilities in the field, though I am not one to attempt to predict these in detail at the present time.

Much has been made of the argument as to whether we should immediately start sending men into space either on satellites or on moon rockets. On manned space flight, it is my feeling that we still have a long way to go on two counts. In the first place, we will not be sure, until we have performed a substantial amount of experimentation, how difficult it is to put a man out there and return him safely. In the second place, we are not sure yet why we want a man to go. Certainly, much of our scientific experimentation and, in fact, some rather distant space exploration can be done without involving manned space flight. I do believe that there are enough possibilities in the long-term future both in military and nonmilitary ventures for a man to be needed in space flight that preliminary experimentation is justified Of course, the country that first puts man into space and returns him safely will make a deep impression on mankind and will gain great prestige. Personally, if I a choice is necessary, I would sacrifice early prestige for long-term strength in this field.

There are several kinds of activities which must be conducted simultaneously in order to develop our capabilities optimally. In scientific laboratories we must conduct research and develop equipment to perform the scientific experiments in space. In engineering laboratories we must work on the techniques and the technical fields which we must master before we can perform vastly more complicated flight into space. The flight work which we conduct must have at least two purposes: (1) To provide the vehicles for the transportation of scientific apparatus to whatever stations in space they must reach to perform the experiments; (2) to develop and test new vehicles and flight techniques.

In considering the organization and program to accomplish all this, you must first note where our capabilities lie. Personally, I am one who believes that

this country has very strong capabilities in this field and that our scientific, engineering, and industrial people will respond quickly to this challenge. There are several sources of this needed talent. In the first place, within the Government we have the National Advisory Committee for Aeronautics with its laboratories and flight stations, the Redstone Arsenal, and others, all of which have already conducted some important experimental work, particularly on flight techniques. There are other Government laboratories which have participated in the program of scientific experiment, the Naval Research Laboratory, the Air Force Geophysics Laboratory, and a number of others. There are a large number of university scientific laboratories which have been involved in the scientific experiments. Finally, we have strong industrial concerns, in which interests in this field primarily came about because of the military vehicles developments, but which have expanded their interests and strengths far beyond. The Government organization which is set up to handle astronautics and space exploration must use all of these strengths.

Without going into great detail about all the possible organizations proposed to do this job, let me say that, for several reasons, I favor the use of the NACA as a nucleus of a new organization to conduct our nonmilitary work in astronautics and space exploration. In the first place, the NACA laboratories have already done, and are continuing to do, a great deal of work in this field, particularly on the flight techniques. In the second place, NACA's relationship with the National Science Foundation and the National Academy of Sciences is such that they can use the important scientific research capabilities which these two organizations have. In the third place, NACA has longstanding close relationships with the military; there is a great overlap in the military and the nonmilitary uses of equipment for space exploration and experimentation. The new organization can use these well-founded relationships, first, to help the military solve its problem, and, second, to help itself by using military equipment.

It is important to consider this a new organization rather than an expanded NACA, for it must have a capability to contract with industry and academic institutions to perform sizable portions of this program. The NACA does not do this at the present time to the extent that will be necessary in this new activity.

Finally, there is one important point which is fundamental to this entire operation. It has to do with the decentralization of authority and responsibility, once the program is decided upon. In those stages in which we are now, essentially, discovering what our objectives are, what our organization should be, and what general program should be followed, I think it is important to tap all of the ideas from all sources. As we begin to carry out this program, we must continue to tap these ideas from capable organizations and individuals to find out what scientific experiments to perform, and to discover what techniques we should use to carry out scientific experiments into space. But, having decided upon an experiment or a program of experiments, I believe it is essential that responsibility and authority be delegated down to the working, technical level. A very complicated superstructure of detailed technical management within the Government, I believe, has seriously hampered some of our most important projects in space technology to date.

I believe that the leaders within the NACA understand this fundamental requirement for rapid progress in a technical venture.

Mr. O'Brien. The committee will be in adjournment until 10 o'clock tomorrow morning.

(Whereupon, at 5:30 p. m., the hearing was adjourned until 10 a. m., Tuesday, April 22, 1958.)

ASTRONAUTICS AND SPACE EXPLORATION

TUESDAY, APRIL 22, 1958

HOUSE OF REPRESENTATIVES,
SELECT COMMITTEE ON ASTRONAUTICS AND SPACE EXPLORATION,
Washington, D. C.

The committee met, at 10:20 a. m., pursuant to recess, in the caucus room, Old House Office Building, Hon. John W. McCormack, chairman, presiding.

Present: Representatives McCormack, O'Brien, Metcalf, Natcher, Sisk, McDonough, Fulton, Keating, and Ford.

Present also: George J. Feldman, director and chief counsel.

STATEMENT OF DR. HUGH L. DRYDEN,[12] DIRECTOR, NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS

The CHAIRMAN. The committee will be in order.

The first witness will be Dr. Hugh L. Dryden, Director of the National Advisory Committee for Aeronautics.

We are very glad to have you appear before us, Doctor. Do you have a prepared statement?

Dr. DRYDEN. Thank you, Mr. Chairman. I have a prepared statement.

On April 2, the President transmitted to the Congress a special message recommending the establishment of a National Aeronautics and Space Agency.

On the same day, on direction of the President, the Director of the Bureau of the Budget transmitted to the Congress a draft of legislation to carry out this proposal.

In essence, the President's recommendation is for establishment of a new, independent Federal agency that will be responsible for programs concerned with problems of space technology, space science, and civil space exploration.

It is further proposed that the new agency, which I will refer to as the NASA, will use the present National Advisory Committee for Aeronautics, NACA, as its nucleus.

---

[12] Dryden, Hugh Latimer, physicist; b. Pocomoke City, Md., July 2, 1898; s. Samuel Isaac and Nova Hill (Culver) D.; A. B., Johns Hopkins, 1916, A. M., 1918, Ph. D., 1919, Sc. D. (hon.), Polytechnic Inst. of Brooklyn, 1949, U. of Pa., 1951; D. Eng (hon.), New York U, 1950, Rensselaer Polytechnic Institute, 1951, married Mary Libbie Travers, Jan. 29, 1920; children—Hugh Latimer, Mary Ruth, Nancy Travers. With Nat. Bur. of Standards since 1918, as lab asst, 1918–19, Asso physicist, chief of aerodynamics sect., 1920–34, chief of mechanics and sound div. since 1934, prin. physicist, 1934–38, head physicist since 1938, asso. dir., 1946–47; dir. National Adv. Com. for Aeros., 1947—; U. S. del. adv. group aero. research and development, NATO. Mem. Nat. Investors Council, Dept. of Commerce, Wilbur Wright lecturer, Royal Aeronautical Soc, London, 1949. Hon. Officer, Civil Div. Order Brit Empire. Editor, Jour. of the Aeronautical Sciences. Hon. fellow Inst Aeronautical Sciences (pres 1943), fellow Royal Aeronautical Soc. (London); mem. Nat. Acad. of Sciences, Nat. Geographic Soc (life mem., board trustees), Am Soc. M. E., Am. Phys. Soc., Washington Acad. of Sciences, Philos Soc (Washington), Phi Beta Kappa, Sigma Xi. Wright Bros. lecturer, Inst. of Aeronautical Scis., 1938. Recipient, Reed Award, Inst. Aeronautical Scis, 1940; Medal of Freedom, 1946; Daniel Guggenheim medal, 1951. Methodist. Clubs: Cosmos. Author books; contbr. to tech. jours. Home 5606 Overlea Rd, Washington 16. Address: 1512 H. St N. W., Washington 25

In addition to its conduct of programs having to do with space technology, space science, and civil space exploration, the NASA will continue the aeronautical research programs of the NACA.

The President has instructed the NACA:

1. To present to the appropriate committees of the Congress a full explanation of the proposed legislation and its objectives.

2. To formulate such detailed plans as may be required to reorient the present programs, internal organization, and management structure of the NACA so as to carry out the functions of the NASA.

3. To plan programs necessary to implement the proposed legislation.

4. To review jointly with the Department of Defense pertinent programs currently underway within or planned by the Department of Defense, and to recommend to the President which of the programs should be placed under the direction of the new NASA.

5. To prepare jointly with the Department of Defense plans to assure that appropriate organizations, facilities, and other functions now within the Department of Defense be used in support of the NASA, either by cooperative arrangements or by transfer to the NASA.

6. To discuss with the National Science Foundation and the National Academy of Sciences, as well as with other governmental and nongovernmental bodies, participation by the scientific community on a continuing basis in the planning and coordination of scientific programs for the use of space vehicles.

My remarks are based on these instructions

I do not believe I overstate the case when I say that the need for the United States to assert its leadership in the fields of space is self-evident.

For the record, however, I should like to quote from the statement by the President's Science Advisory Committee, Introduction to Outer Space, dated March 26, 1958. Dr. Killian's group lists four factors that "give importance, urgency, and inevitability to the advancement of space technology," as follows·

> The first of these factors is the compelling urge of man to explore and to discover, the thrust of curiosity that leads men to try to go where no one has gone before. Most of the surface of the earth has now been explored, and men now turn to the exploration of outer space as their next objective.
>
> Second, there is the defense objective for the development of space technology. We wish to be sure that space is not used to endanger our security. If space is to be used for military purposes, we must be prepared to use space to defend ourselves.
>
> Third, there is the factor of national prestige. To be strong and bold in space technology will enhance the prestige of the United States among the peoples of the world and create added confidence in our scientific, technological, industrial, and military strength.
>
> Fourth, space technology affords new opportunities for scientific observation and experiment which will add to our knowledge and understanding of the earth, the solar system, and the universe

The draft legislation is explicit in declaring that our national space program shall be controlled by a civilian agency, except, and I quote—

> insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations

You gentlemen are familiar, I am sure, with the views of both the President and his science advisers that the nonmilitary implications

of space are so important as to require civilian, rather than military, control of the program.

I have the further thought, which I believe to be shared largely by the scientific community, that the extremely important, nonmilitary aspects of space might well become submerged, or perhaps, even lost, if included as an adjunct to a military program.

Recently, some doubt has been expressed that there will be widespread military application of the advances we make in space, except for reconnaissance and communication.

My own feeling on this point is that, today, we just don't know enough to predict with accuracy how much or how little of military value will accrue.

Instead of seeking in these beginning minutes of the space age to determine in great detail the full range of future military uses of space vehicles, we might better concentrate our efforts on the many, massive problems that require solution for us to explore our solar system.

On this point, I should like to be clear. We must enlarge and extend our effort to solve these large and difficult problems. I am confident that, as we make progress, there will unfold multiple uses for space flight, both civilian and military.

A half century ago, as Wilbur and Orville Wright were preparing to sell the first military airplane to the United States, a controversy had already begun that lasted many years. On the one hand were vigorous advocates of the airplane who reasoned that just as "he that commands the sea is at great liberty," so would he who gained control of the air control the world.

On the other side were those who argued that the crude, fragile airplanes of that day, underpowered by engines of dubious reliability, could hardly be expected to be of much military value.

Of course, the first airplanes were of very little use, but, over the years, research and development brought great improvements in the airplane, and we all know the profound changes that resulted.

Since 1915, when it was established by Congress, NACA has been charged with the responsibility to—

> supervise and direct the scientific study of the problems of flight, with a view to their practical solution * * * and to direct and conduct research and experiments in aeronautics.

Over the years, NACA has interpreted this to mean that its primary task was to provide the aircraft industry and the military services with information and technical data of a fundamental nature that would assist them in constantly improving military and civilian aircraft and missiles.

Since the end of World War II, NACA has been engaged increasingly in research applicable to the problems of space flight. It has designed and constructed special aerodynamic, propulsion, and structures research facilities required for this work.

At this point, Mr. Chairman, I should like to put into the record a chart showing the present organization of NACA and the effort being placed on space research.

I should also like to put in the record an unclassified version of a classified document describing some of this work in a little more detail.

The CHAIRMAN. Without objection, it is so ordered.

Dr. DRYDEN. Thank you, sir.

(The material referred to follows:)

NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS

NACA RESEARCH INTO SPACE

INTRODUCTION

In this technological age the country that advances most rapidly in science will have the greatest influence on the emotions and imagination of man, will have the greatest rate of industrial and economic development, the highest standard of living, and the greatest military potential, and will command the respect of the world. The scientific advances of the Soviets in their bid for world supremacy have been amply demonstrated by the recent success of their satellite program. These advances are the results of a far-reaching plan and sustained effort that poses a most serious challenge to the United States and the Western World. It is of great urgency and importance to our country both from consideration of our prestige as a nation as well as military necessity that this challenge be met by an energetic program of research and development for the conquest of space.

This task requires rapid extension of knowledge into regions already familiar and penetration into still unexplored areas. Urgency dictates the maximum effective utilization of existing facilities, knowledge, and organizations. The NACA is an organization in being, already engaged in research applicable to the problems of space flight and having a great many of the special aerodynamic, propulsion, and structures facilities required, and qualified to take prompt advantage of the technical training and interest of scientists competent to help in the research on space technology. During the past half century this country achieved and later exploited world leadership in solving the problems of flight. The NACA, in partnership with the military services, other branches of the Government, the scientific community, and industry has played a leading role in this achievement.

The NACA in 1952 formally initiated studies "of the problems associated with unmanned and manned flight at altitudes from 50 miles up, and at speeds from Mach 10 to the velocity of escape from the earth's gravity." Since that date, the NACA's major aeronautical research centers and field stations have concentrated increasingly upon solution of problems of ballistic missiles, hypersonic aircraft, and space vehicles.

The objective of this document is to present briefly information about current NACA research having application to missiles and space flight.

NACA's part of the critical challenge now facing the Nation can be met with an expanded NACA program and with the support of the Congress for the needed additional manpower and research equipment.

MISSION OF THE NACA

The National Advisory Committee for Aeronautics was established as an independent Government agency reporting to the President by act of Congress of March 3, 1915, and authorized to "supervise and direct the scientific study of the problems of flight, with a view to their practical solution * * * and to direct and conduct research and experiment in aeronautics" (50 U. S. C. 151).

During the past 42 years, the National Advisory Committee for Aeronautics has sought to assess the current stage of development of aircraft to anticipate the research needs in connection with the problems of flight; to build the scientific staff and unique research facilities required for these research needs; and to acquire the new knowledge as rapidly as the national interest requires.

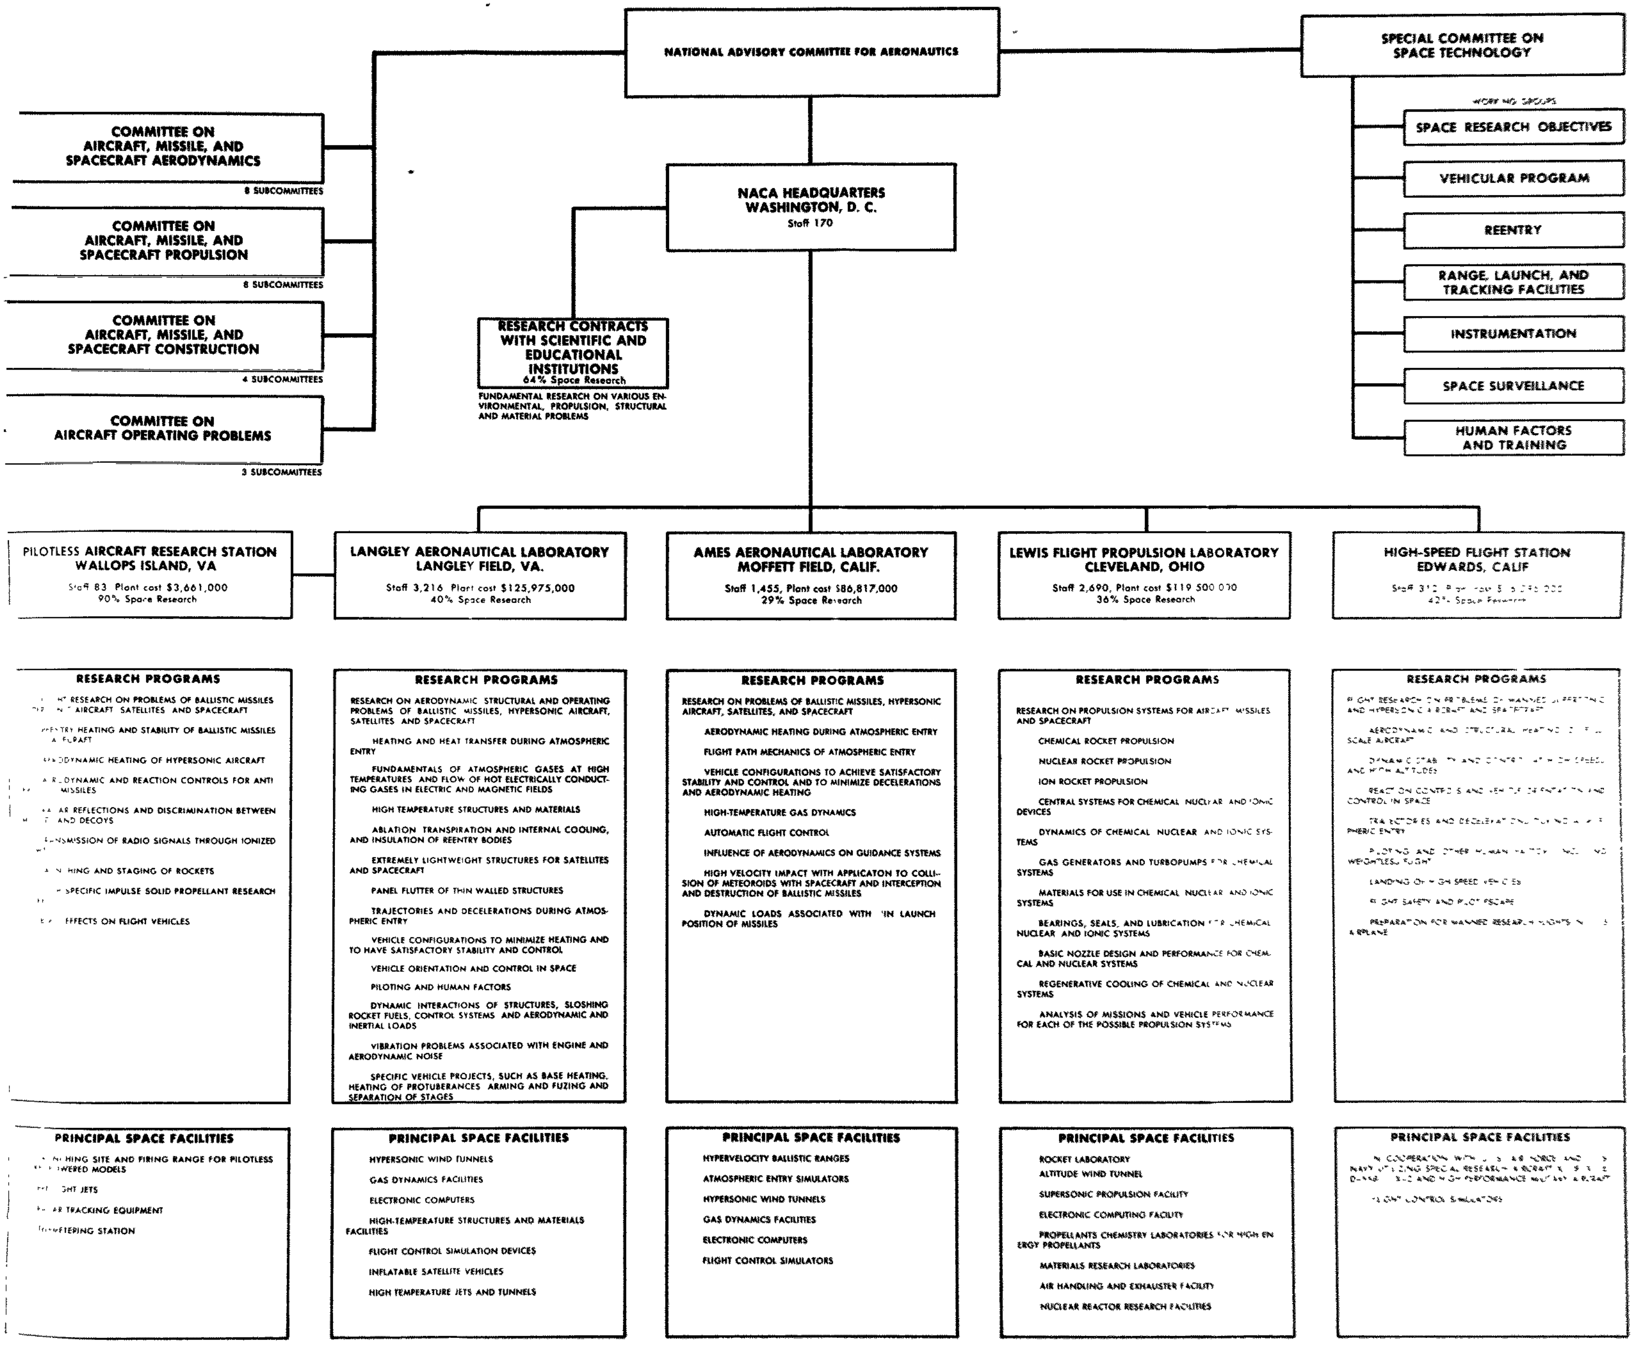
By discharging its primary responsibility—scientific research—NACA serves the needs of all departments of the Government.

The 17 unpaid members of the NACA are apopinted by the President and report directly to him. They establish policy and plan the research to be conducted by the 8,000 scientists, engineers, and supporting personnel who comprise the staff of the Agency.

The membership of the NACA and its broadly based technical subcommittees, including NACA's Special Committee on Space Technology, includes personnel from both military and civilian agencies of the Government and representative scientific and engineering members from private life, thus assuring full coopera-

NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS

ORGANIZATION AND DISTRIBUTION OF EFFORT RELATED TO SPACE RESEARCH FOR THE FISCAL YEAR 1958



tion with the military services, the scientific community, and industry. NACA's organization has proved to be an effective national research and coordinating body.

The NACA's research programs have both the all-inclusive, long-range objective of acquiring new scientific knowledge essential to assure United States leadership in solving the problems of flight and the immediate goal of solving, as quickly as possible, the most pressing problems.

The scientific research is conducted at NACA's major research centers: Langley Aeronautical Laboratory, Virginia; Ames Aeronautical Laboratory, California; and Lewis Flight Propulsion Laboratory, Ohio. Flight research is also conducted at the high speed flight station, California; and the pilotless aircraft research station, Virginia.

AERODYNAMICS AND SPACE MECHANICS

In recent years the research of the NACA has been directed increasingly to the problems of aerodynamics at the hypersonic speeds required for flight beyond the atmosphere. The objectives of this research include:

1. More fundamental understanding of airflow characteristics and high-temperature conditions occurring at hypersonic speeds as during reentry to the earth's atmosphere, including the physical and chemical changes in the air and the effects of these changes on the flow.
2. Information about the heat transfer and forces applied to ballistic missiles and hypersonic and space vehicles.
3. Information about stability, control and guidance requirements, and means for satisfying these requirements for flight both within and outside the atmosphere.
4. Evolution of missile and space vehicle configurations of various kinds, compatible with propulsive and structural requirements, and capable of performing useful scientific or military missions under all the conditions of environment and speed imposed by the desired flight plans.

NACA research in this area has included work on the problems of both missiles and manned aircraft. With respect to the difficult ballistic missile reentry problem, the NACA contributed in 1952 the concept of the high-drag, blunt warhead to minimize aerodynamic heating. All current ICBM and IRBM warheads employ this concept. Successful reentry has been achieved with an intermediate range ballistic missile nose cone designed according to this principle. Work is now being directed toward advanced nose cones which have higher impact speeds. This will permit design of ballistic missiles that will achieve improved target accuracy and be more difficult to intercept.

In addition to ballistic missiles, the NACA has concerned itself with problems peculiar to antiballistic missiles. The studies include the aerodynamic requirements of antiballistic missiles to permit them to perform their mission without undue electronic complexity. Effort is also being exerted to obtain configurations having desirable characteristics of speed and maneuverability and to solve the very difficult problem of control to achieve interception in the upper reaches of the atmosphere.

Interest in manned flight at hypersonic speeds and in space led the NACA to make the proposal which resulted in the cooperative NACA-USAF-USN project, the X–15 research airplane designed and now under construction for studying some of the problems of manned flight in nearby space. This airplane is designed to reach altitudes where the aerodynamic forces will be negligible to permit study of problems of flight mechanics and reentry into the atmosphere of a piloted vehicle. This proposal was made 2 years before the X–2 research airplane exceeded a speed of 3 times the speed of sound and reached an altitude in excess of 25 miles. Space controls in the form of small rockets are provided as well as aerodynamic controls. Space controls have been installed in an older research airplane which is now being flown to study the problem of merging space controls at high altitudes with aerodynamic controls at lower altitudes.

One important aspect of this program has been concerned with man's ability to operate the vehicle and its dynamic behavior, both within and beyond the atmosphere. Laboratory simulator studies using research pilots have identified conditions of dangerous divergent motions during exit and reentry, and provided information on stabilization and control requirements.

For more than a year the NACA has been making an intensive study of the feasibility of a research hypersonic glider with an airframe capable of flight at

all speeds up to satellite velocity. Such a vehicle would be capable of exploring the problems of manned space flight and reentry at extreme speeds including aerodynamic heating, orientation, navigation, aeromedicine, and electronics. The vehicle envisioned would be capable of extensive gliding within the upper atmosphere and of landing in a normal manner at a large airbase. Exploratory studies are also underway on alternate approaches to the operation and recovery of manned satellites These alternates would employ a lighter vehicle which, however, may be less flexible in operation. Although many problems remain to be solved, no insuperable difficulties have been discovered. These studies are now serving, in no small measure, to channel into proper direction research on the increasingly urgent problems of space flight.

Many types of existing NACA laboratory facilities are being used to contribute to the solution of ballistic missile, hypersonic aircraft, and spacecraft problems in aerodynamics. Even subsonic and transonic wind tunnels, as well as high-speed equipment, are being used effectively in studies of such problems as dynamic stability, fusing of warheads during reentry, the magnitude of hinge moments on gimbaled rockets used for control during powered flight, and landing characteristics of hypersonic aircraft.

Supersonic and hypersonic wind tunnels, hot jets, and hypersonic ballistic ranges are being used to study many problems, especially those involving boundary-layer effects and heat transfer.

Small tunnels using air provide speeds up to a Mach number of about 10, and larger equipment is now under construction. Helium has been used in small wind tunnels to simulate Mach numbers up to 20, and procurement of larger equipment for this purpose is now underway. A large new wind tunnel will provide a hypersonic airstream from a pebble-bed heater with temperatures in the 2,500° to 3,000° F. range. Smaller equipment already in use employs pebble-bed heaters at temperatures to about 4,000° F. Combustion heated jets cover an even larger range of temperatures.

The wind tunnel cannot, however, provide complete temperature simulation in air at the higher hypersonic speeds because of material limitations. The NACA is placing much effort on the development of other types of high-temperature apparatus to study the physical and chemical changes in air at hypersonic speeds Small air jets from electric arcs are providing temperatures up to about 15,000° F., but further technique development is required. Shock tubes are also being used to provide high temperatures, but their usefulness is currently limited by very short durations and by the low Mach numbers of the flow. Developments are now underway to obtain high-temperature hypersonic airflows with useful flow durations

One of the most valuable research tools is the hypersonic ballistic range which provides simulation of both speed and temperature effects in air. Guns and methods of using them to propel models of useful shape and size already have been developed to reach Mach numbers of about 15. Equipment now under construction will increase substantially this speed. In one variation of the ballistic range, the model is shot upstream into a special supersonic wind tunnel to obtain higher speeds than are obtainable by gun launching into still air.

A small atmospheric reentry simulator is also being used, in which the model of a ballistic missile nose cone is shot upstream in a special nozzle of a supersonic wind tunnel. A large reentry simulator, now under construction, will provide conditions equivalent to those experienced by large, long-range ballistic missiles and satellites.

Although every effort is being made to improve our ability to simulate the actual conditions of speed, scale, and temperature in laboratory facilities, complete simulation of all conditions simultaneously is possible only in flight. The pilotless aircraft research station at Wallops Island, Va., established 12 years ago to obtain aerodynamic data at transonic and low supersonic speeds, is now being used almost exclusively on hypersonic and space flight problems. Data are currently being obtained, for example, from models of ballistic missiles and spacecraft accelerated downward from the top of their trajectories to Mach numbers as high as 16. The models are propelled by multiple staging of solid-propellent rockets. This low-cost system has demonstrated simplicity and reliability of operation. Work is underway to increase the speed of simple research rockets to satellite and perhaps escape velocities in the not-too-distant future. The ground range facilities and highly developed, specialized telemetering instrumentation available permit the measurements needed for a wide variety of aerodynamic, structural and material investigations.

Recent NACA rocket-flight research has made contributions to the knowledge of transition from laminar to turbulent boundary-layer flow which is important to heat transfer to both ballistic missiles and hypersonic winged vehicles. In addition to such research, a number of rocket-powered model flights have been made to obtain specific information about the ICBM and IRBM warhead shapes now being developed for the military services.

PROPULSION

Powerplants for spacecraft must accomplish three objectives (1) Provide sufficient velocity to overcome the earth's gravitational field; (2) provide sufficient velocity control, both in magnitude and direction, to permit the desired flight path in space, and (3) provide such auxiliary power as is required. NACA propulsion research is being directed to the accomplishment of these objectives.

To meet the first objective, the thrust must exceed the gross weight by a sufficient amount so that the energy consumed in overcoming gravitational force is not an excessive fraction of the total energy available On the other hand, the thrust-to-weight ratio should not be so high that final accelerations exceed allowable limits.

In order to meet the second objective, velocity and directional control must be available throughout the entire mission, which may be measured in terms of days or months. Hence the rate at which the propellent is consumed becomes at least as important as the thrust-to-weight ratio; powerplants such as the ion rocket having thrust-to-weight ratios in the range from one-thousandth to one ten-thousandth become of interest since their propellent consumption rate is very low.

For auxiliary power, the weight per unit of power output must be as low as possible. The weight of the energy source carried is also important, but in many missions the possibility exists of using an exterior energy source, such as the sun. The choice between external and internal energy sources will depend on the duration of the mission, the total energy requirement, and the relative weights of each source and its associated equipment.

To satisfy the above requirements, NACA studies are being made of the (1) energy sources available—chemical, nuclear, solar; (2) the working fluids to be used—combustion products, lightweight gases, ions, plasma, photons; (3) possible heat transfer fluids—gases or liquids; (4) the mechanical devices by which the energy is converted into thrust or power—nuclear or chemical rockets, ion, plasma, or photon jets; (5) the particular steps traversed from energy source to thrust or power—nuclear or chemical energy to heat or to electricity, and thence to acceleration of the working fluid; (6) the methods of controlling the powerplant, and (7) the materials of which the powerplant is made and the environment in which they operate.

Current NACA rocket research is concerned primarily with rocket engines of high performance for space and ballistic missions. Investigations involve a variety of theoretical and experimental work. The theory includes the study of rocket cycle thermodynamics, flight dynamics, and the calculation (by use of digital computers) of the combustion gas temperature and composition under a variety of conditions, and the vehicle performance that may be realized. Experiment includes studies of the basic injection processes of propellent mixing and atomization; relative reactivity of fuel-oxidant combinations, ignition and starting transients, combustion instability, and heat-transfer processes. There are in addition studies involving liquefied gases. This research is concerned with suitable means for pumping, piping, and control systems for liquefied gases as propellents. Methods of cooling of rocket engines with the liquefied propellent gases are also under study.

Specific NACA research projects have been completed on fundamentals of ignition at altitude and low temperature with self-igniting propellents; solutions to the ignition problem in the form of fuels for use with the storable liquid oxidizer (nitric acid); performance parameters of propulsion systems, basic studies of combustion instability to clarify the mechanism and to control it, and the selection of propellents for research for high performance missions. In the research propellents on high impulse, emphasis has been on hydrogen and hydrazine with either oxygen or fluorine as an oxidant. The heat transfer characteristics of high-energy liquid propellents are under study. Fluids being studied are hydrogen, fluorine, oxygen, nitrogen, ammonia, and water.

Since 1950, the NACA has studied the application of nuclear energy to aircraft and rocket propulsion systems. This work includes cycle analysis, heat

transfer, shielding, materials, and reactor physics. Of particular interest to nuclear rockets for space propulsion is a current program to determine the compatibility of uranium compounds with various high-melting structural materials at temperatures of 5,000° F. and above. This work supplements, and is being done in coordination with, the work of the AEC Los Alamos Laboratory. A 60-megawatt research reactor is being constructed near Sandusky, Ohio, to further research on the effects of heat and nuclear radiation on powerplant materials and components. This facility will permit investigation of complete heat transfer loops for the primary propulsion and auxiliary power systems required in controlling or sustaining space flight.

As a guide for experimental studies and to place the numerous possible powerplant systems in their proper perspective, extensive analytical studies have been made comparing the relative merits and areas of application of nuclear- and chemical-fueled vehicles. Results of these studies were presented to industry and the armed services in our 1957 flight propulsion conference.

In the chemical rocket the working fluid and the energy source are the same. Since this is not true in the nuclear rocket, the ion jet or the plasma jet, and therefore a choice may be made from a wide range of fluids, research on the characteristics of the fluids suitable for use in these devices is being conducted. Effort is being directed toward obtaining a low ratio of power required for thrust produced. Launching a spacecraft requires research on the complete rocket propulsion system from the liquid propellent tanks to the exist of the exhaust nozzle. The NACA is conducting research on the turbomachinery required to transfer the propellent from the propellent tanks to the combustion chamber, on the propellent injection system which is a major factor in determining combustion efficiency and stability, on the combustion process and on the effect of discharge nozzle design.

The 15 years of NACA research on turbomachinery for the turbo-jet engine provides a background of research data and personnel directly applicable to rocket turbine and pump systems for IRBM, ICBM, and spaceflight. The need for high pumping power and lightweight require the use of high-speed turbines and pumps. The corrosive nature of some of the oxidants requires special attention to materials, lubricants and seals; a research program to supply solutions to the materials, lubricants, and seals problems with corrosive oxidants is being vigorously pursued.

As solid propellent specific impulses are increased to the point where they can be used for spacecraft, research will be required on methods for controlling thrust time history and the interrelation of this and the guidance system. The exit nozzle research and much of the combustion research already discussed is applicable to solid as well as liquid propellent ballistic and space vehicles. As facilities become available, research in the solid propellent field is being expanded.

Existing facilities have been used to make investigations of critical problems associated with the design of the Thor and Jupiter missiles.

Work applicable to powerplants to provide the energy for ion jets or plasma jets has begun. For the most part this work is in the analytical stage. Emphasis from the weight standpoint is on the power producing unit rather than the propellent accelerating unit. The analyses being conducted on these systems indicate the need for research on higher temperature and more efficient power generators. Solar energy is being studied but currently only in the analytical field.

The control precision required by spacecraft, including IRBM's or ICBM's, necessitates more precise control of fluid flows, and of mechanical equipment operation than has been required previously for flight within the atmosphere. The controls research conducted at the Lewis Laboratory is being channeled into the spacecraft requirements.

Spacecraft powerplants demand a high order of operational reliability for times varying from a few minutes to many days. To achieve such reliability places severe demands on materials and the ingenuity of their application. This is particularly true in view of the very high working fluid temperatures required. The NACA materials research for chemical and nuclear rockets has two objectives: (1) To obtain the maximum temperature possible either by improving material physical properties or through cooling, and (2) to improve the operational life and reliability. Structural material requirements for ion and plasma jets are still not well defined. Emphasis on the materials studies is being given to molybdenum and tungsten metal groups and to ceramics.

STRUCTURES AND MATERIALS

Successful operation of long-range ballistic missiles and manned spacecraft depends in no small way upon structural ability to cope with the very large range of aerodynamic and thermodynamic loads and stresses experienced. The same structure that withstands the extremely large thermal and erodynamic loads and stresses generated during exit from and reentry into the atmosphere must also be strong during flight outside the atmosphere where temperatures are very low and there is always present the danger of hypervelocity impact with meteoric dust and larger meteoroids.

The increasingly large part of NACA research on structures and materials applicable to the design of missiles and spacecraft must of course consider load and stress conditions imposed throughout the entire flight mission. Remembering that minimizing weight is the overall goal of structures and materials research, some of the more specific objectives of this research include:

1. Establishment of the interactions of heat, aerodynamic force, structural elasticity, and inertia, thus to aboid destructive vibration phenomena.
2. Evaluation of structural configurations for various temperature ranges, including for the highest temperatures, composite arrangements that incorporate cooling, insulation, and heat shields.
3. Determination of properties and behavior of structures at high temperatures and under transient heating.
4. Evaluation of the heat-resistant capabilities of existing materials and their applicability to space structures, ballistic missiles, and hypersonic aircraft.
5. Development of new materials with improved high-temperature properties such as are required for reentry into the atmosphere at hypersonic speeds.

To determine the complete behavior of missile and aircraft structures at high temperature it is necessary to perform the tests in an airstream of suitable speed. As early as 1952, use of the NACA's first supersonic true-temperature wind tunnel made possible isolation and study of a previously unknown form of destructive flutter caused by thermal stresses brought on by transient heat flow. The data from this facility made possible, in advance of production, structural changes in the design of several missiles and supersonic airplanes then being developed.

Recently a major supersonic facility known as the 9- by 6-foot thermal structures tunnel has been completed and put into operation. It permits study of much larger structural specimens under conditions of high heating rates and at temperatures to 700° F. A more advanced version of this type of facility is now being designed to permit testing of equally large specimens to 4,000° F. and at hypersonic speed.

Missile structures which are subjected to constantly changing loads and temperatures in their flight through the atmosphere have also been improved in NACA's laboratories by studying them under timed programs of load and temperature that simulate their flight.

Important examples of recent structural studies relating to hypersonic flight are those for the X-15 and the projected research hypersonic glider capable of satellite speeds. Although the X-15 is to be used in study of the severe heating problems experienced at high speeds it was found possible to use relatively conventional structures. Original studies included tests of various box beam configurations with both load and heat input programed in accordance with anticipated flight conditions. Buckling stresses, ultimate strength, and deflection characteristics were determined. Vibration tests also have been made to determine modes and frequencies of the hot structure, and the loss of stiffness resulting from heat.

Theoretical and experimental studies have been made of various types of sandwich panel configuration suitable for the structure of a hypersonic glider. These investigations include panel flutter tests under heated conditions, and studies of the relative efficiencies of bare structures of refractory materials and structures with heat-shield, insulation, and cooling systems.

Research on materials is centered largely on their properties and behavior under the conditions of reentry in space flight. Mechanical properties of many alloys have been obtained under conditions of transient heating. Total heat capacities have been determined for a variety of metallic and nonmetallic materials. Various protective coatings for refractory metals and other materials have been tested. Means have been provided for coating metals with high emissivity materials that remain stable at high temperatures. Relative ablation rates have been established for many materials under high-temperature

conditions. Impact studies have been made with various combinations of materials over a wide range of Mach numbers. Fundamental information regarding penetration and cavitation volume under impact also has been obtained.

The severity of the reentry problem and the demand for materials with high temperature capabilities have led to attempts to improve existing materials and to develop new ones. In this area the causes of brittleness in ceramic materials are being investigated with the hope that development of ductile ceramics may be possible.

Hot air jets employing ceramic heat exchangers that operate at 4,000° F. are currently playing an important role in this study of materials for ballistic missile nose cones and spacecraft reentry vehicles. One of these jets will soon be extended to have a 5,000° F. hypersonic airstream 12 inches in diameter.

The NACA has also developed air jets heated by high intensity a. c. electric arcs. Currently in operation is an apparatus that produces a M–2 air jet of ½-inch diameter and temperature of 12,000° F. Under design is a similar facility that will permit testing of 6-inch diameter models to temperatures above 20,000° F. with heating rates to 10,000 Btu/sq ft./sec and under correct conditions of Mach number and air density for the reentry problem.

Other hot jets employing ethylene or rocket fuels to produce temperatures from 3,500° F. to 8,000° F. are being used for studies of melting and ablation, and for quick comparisons of materials for which oxidation is not a factor.

Such equipment as the ballistic ranges and atmospheric reentry simulator mentioned previously, while designed primarily for aerodynamic study, are also used for study of some materials problems. This has been true especially in the case where the high velocity impact of meteoroids has been simulated. Data also are being obtained on materials and structural properties using NACA-developed hypersonic rocket techniques.

Although high temperature predominates as the newest and most difficult environmental factor affecting the structure and its material, many problems at ordinary temperatures remain. Moreover, insight into the complicated high-temperature problem is provided by the background of research performed by the NACA over a period of many years. Results of research on strength, buckling, stiffness, efficiency, and vibration modes of many structural configurations of wings, cylinders, tapered bodies, et cetera, have found their way into missile hardware.

Important flutter and vibration problems also continue to be studied at ordinary temperatures. The cylindrical structures of large rocket boosters are thin-skinned and subject to panel flutter, fuel sloshing loads, and acoustic excitation. Studies of these dynamic phenomena also include the effects of coupling of the vehicle control system with its structural dynamics.

Dr. DRYDEN. We have made available to the committee the classified version, which includes some aspects which cannot be put into the open record.

I would be remiss if I did not note that this essential development of new research techniques and new research tools by the NACA would have been impossible except for the support Congress has given. The facilities at the NACA research centers and field stations have cost more than $350 million, every dollar of which has been appropriated by the Congress. Some 20 years ago, the respected British Journal, Aircraft Engineering commented editorially on the NACA practice of pioneering in its research programs, as follows:

> The present-day American position in all branches of aeronautical knowledge can, without doubt, be attributed mainly to this far-seeing policy and expenditure on up-to-date laboratory equipment.

The same statement, I believe, could be made with equal validity respecting today's work of NACA to acquire new knowledge about aerodynamics, materials, structures, and propulsion.

A second important role of NACA since 1915 has been coordinating aeronautical research in the United States. Through the members of the main committee and its 28 technical subcommittees, the NACA has linked the military and civil Government agencies concerned with

flight. The aviation industry, allied industries, and scientific institutions have also been represented. Today, nearly 500 men are serving on these committees. They are chosen because of their technical ability, experience, and recognized leadership in a special field of competence. They are acting in a personal and professional capacity as they give of their time and talent, without compensation. They furnish assistance of great value in considering problems related to their technological fields. They review research in progress at NACA laboratories and in other establishments, they recommend new research to be undertaken, and they assist materially in the coordination of research programs.

Our committee structure has not been a mechanism for obtaining group approval of the recommendations and actions of NACA's professional staff. Rather, it has proved to be an extremely helpful device, with the committees serving as forums in specific technical areas. Informed and free discussion at these meetings has produced much useful material to help the staff in programing its research effort.

By way of illustration, I should like to tell you about one of these technical groups, the NACA's committee on aerodynamics. At its regular meeting, January 30, 1952, the 22 members of the committee considered a special presentation by a fellow member, the late Robert J. Woods of Bell Aircraft Corp. Its title was "Establishment of a Study Group on Space Flight and Associated Problems." Mr. Woods called for basic research on, and I quote, "the mechanics and problems of space flight." Mr. Woods suggested that NACA was the logical organization to carry on the basic studies in space flight control and stability as it is a logical extension of work now being done by the NACA, and urged that NACA establish a concept of a suitable manned test vehicle and that as soon thereafter as possible, such an airplane be built.

These proposals, I remind you, were made nearly a year before man first flew at twice the speed of sound. Incidentally, that man was an NACA research pilot. These recommendations made in January 1952, for manned exploration into nearby space at speeds more than 6 times the speed of sound (3,960 miles per hour) have resulted in the cooperative X–15 research airplane program in which NACA has the responsibility for technical direction and in which the Air Force, the Navy, and the aircraft industry are participating.

The sequence of events leading to the awarding of contracts late in 1955 to North American Aviation, Inc., and Reaction Motors, Inc., for construction of the airframe and powerplant, respectively, was as follows: After consideration by the main committee, the NACA staff began studies of the "problems associated with unmanned and manned flight at altitudes from 50 miles up and at speeds from Mach No. 10 (about 6,600 miles per hour) to the velocity of escape from the earth's gravity (25,000 miles per hour).

Intensive programs were conducted at the NACA research centers to provide technical information that was essential in the undertaking of such a project. About this time, NACA's Ames Aeronautical Laboratory solved the atmosphere reentry problem for ballistic missiles. Further NACA research provided information vital in the shaping of wings and control surfaces. These contributions were directly applicable to the X–15 program. In this work, special re-

search facilities, made available by the congressional appropriations in previous years, proved of great value.

By 1954, NACA had sufficient information to present to the Air Force and Navy a detailed proposal for design and construction of an aircraft capable of the extremely high speeds and altitudes necessary for exploration into nearby space. A memorandum of understanding, establishing the procedures to be followed in acquiring and using the rocket plane, was signed by the Air Force, Navy, and NACA. Thereafter, manufacturers were invited to submit their proposals. This airplane will make its first flights next year.

The X–15 will incorporate many design innovations. One example is its control system. Because the airplane will fly to heights where the air is extremely thin, aerodynamic controls will be ineffective. Consequently, it was necessary to devise new controls that work on the jet-reaction principle. For the past year, NACA pilots have been flying a research airplane fitted with this new kind of space control system.

Even as the work is pushed to complete the X–15 and begin man's first exploration of nearby space, steps similar to those I have outlined are being taken on projects that will be needed to enable man's venturing still farther into the unknown.

I have discussed in detail the committee mechanism employed so successfully by NACA because it is a device that will be equally useful in the new fields of space. Last fall, NACA Chairman James H. Doolittle appointed a special committee on space technology. Time was required to permit the top-ranking people chosen for this task to rearrange their workloads in order to serve. Several meetings have been held and working groups are now busy on specific problems.

This committee is headed by Dr. H. Guyford Stever, associate dean of engineering at Massachusetts Institute of Technology. He formerly was chief scientist of the Air Force. The committee includes H. Julian Allen, NACA Ames Aeronautical Laboratory; Col. Norman C. Appold, United States Air Force; Dr. Hendrik W. Bode, director of mathematical research, Bell Telephone Laboratories; Dr. Milton U. Clauser, director of aeronautical laboratory, Ramo-Wooldridge Corp.; Prof. Dale R. Corson, Cornell University; James R. Dempsey, manager, astronautics division of Convair; Robert R. Gilruth, NACA Langley Aeronautical Laboratory; S. D. Hoffman, general manager, Rocketdyne division of North American Aviation, Inc.; Abraham Hyatt, Navy Department; Dr. W. Randolph Lovelace II, Lovelace Foundation for Medical Education and Research; Dr. William H. Pickering, director, jet propulsion laboratory, California Institute of Technology; Dr. Louis N. Ridenour, Jr., missile systems division of Lockheed Aircraft Corp.; Abe Silverstein, NACA Lewis Flight Propulsion Laboratory; Dr. James A. Van Allen, department of physics, State University of Iowa; and Dr. Wernher von Braun, Director, Operations Division, Army Ballistic Missile Agency.

For NACA to become the nucleus of the NASA and to accomplish promptly and effectively the heavy responsibilities that are outlined in the legislative draft submitted at the direction of the President, considerable reorientation of present research programs will be necessary. As a matter of fact, NACA has been reorienting its research effort for several years. We have, for example, shifted much of our powerplant emphasis from air-breathing engines, which are now

reaching an advanced state of development, to rocket engine types. These latter can be used not only to propel ICBM's and satellites, but to send, first unmanned and then manned, spacecraft to the moon and beyond. Similarly, the work we are doing on structures and structural materials is now being focused on problems peculiar to missiles and vehicles that travel beyond the earth's atmosphere. At the same time, these structures have to be suitable also for flight within the earth's atmosphere at the beginning and final stages of any journey. Also, they have to be able to withstand the extremely high temperatures generated by aerodynamic heating. Useful research on this latter problem already has been accomplished; more remains to be done. Fortunately, new NACA research tools, design, and construction of which has been made possible because of appropriations in recent years by the Congress, are now becoming available.

The President's recommendations call for the proposed NASA to study the problems of flight "within or outside the earth's atmosphere with a view to their practical solution." Very few people in aviation believe that the potential of the airplane has been fully attained for either military or commercial purposes. Further, it appears that, as in the past, the key to continued progress in aviation is research, intelligently planned and vigorously prosecuted. Fortunately, many of the problems affecting the launching and recovery of space vehicles are the same as those demanding solution if our airplanes are to reach their desired performance potentials. In my considered judgment, it would be a grave error to attempt separation of the research programs needed for aeronautics from those of space technology.

We are making plans with regard to our internal organization and the management structure of the NACA, to assure that the expanded operations, especially in the areas of space vehicle development and use, be promptly and efficiently undertaken. Although these plans have not been finalized, they will include new elements as well as the effective operating mechanisms evolved by NACA over the past 43 years.

In particular, you will note in the bill provision is made for contract operations on a much wider scale than has been used by NACA in the past.

We are also planning additional actions and programs that will be necessary to assure rapid implementation of the proposed legislation. This planning includes determination of the requirements for additional staff, facilities, and funds that will be needed. In connection with the draft legislation transmitted to the Congress on April 2, 1958, the Director of the Bureau of the Budget submitted a preliminary, minimal estimate that the expenditure of NASA, over and beyond the current $100 million budget of NACA, would range from $100 million in fiscal year 1959 to $300 million in the fiscal year 1962. Those are expenditures and not appropriations. In the near future, we will submit detailed requests for appropriations in support of proposed programs.

We have undertaken, with officials of the Department of Defense, the review requested by the President of pertinent space programs currently underway or planned by the Department of Defense. These include the several programs announced March 27 at the White House, which will permit unmanned exploration of space in the vicinity of the moon. The programs might have been called lunar probes.

I might say at this point that we are determined to take no action which will delay or interrupt the programs which have been approved.

I, for one, might be concerned about the difficulties that could be expected to occur in the process of determining what current and planned Department of Defense space programs should be placed under the direction of the NASA were it not for the fact that for the past 43 years the military services and NACA have worked together, cooperatively, and what is more important, effectively. Just because we will be venturing into unknown areas of interplanetary space is no reason why this happy, essential partnership arrangement needs to change.

I should like now to consider the relationship of NASA with other agencies. As we learn to fly farther into space, carrying man some day on exploration flights to the planets, the idea of exploiting the great potential of nuclear energy becomes more attractive and perhaps even essential. Since the war, NACA has worked closely with the Atomic Energy Commission in studying problems of aircraft and rocket engines using nuclear energy. AEC effort has been concentrated upon problems peculiar to nuclear powerplants. NACA's effort, in turn, has been focused on problems of how to exploit the potentialities of such engines, incorporating them in aircraft and missiles. There has been close coordination of this continuing work. AEC personnel have served on NACA committees; NACA technical people have worked similarly with AEC groups. The future relationship, between AEC and the NASA, can be expected to be even more intimate, but I foresee no fundamental change.

In the past, the NACA has concentrated for the most part on flight problems in the fields of aerodynamics, propulsion, and structures and structural materials. These are the areas where NACA has the greatest competence and the best research tools. Flight into space requires that great effort also be devoted to such problems as electronics, guidance, and physiology or human factors. We plan to make substantial use, by contract, or organizations with competence already demonstrated in these related fields of technology.

As indicated earlier, a most important part of our national space program must be the effective use of space vehicles to collect information of value to the scientific community.

It is imperative that the best scientific judgment available be employed to determine space science objectives, and to this end it will be necessary that the NASA work most closely with the National Science Foundation and the National Academy of Sciences.

Parenthetically, I would refer to the paper dated February 14, 1958, by the Technical Panel of the Earth Satellite Program of the United States National Committee for the National Geophysical Year, National Academy of Sciences, which is entitled "Basic Objectives of a Continuing Program of Scientific Research in Outer Space." I believe this has been published in a congressional document. To both the scientist and the layman, this is a fascinating outline of the new knowledge that can be acquired through the effective use of our newest of research tools, the space vehicles.

Finally, I wish to discuss in a general way some aspects of the space programs we will be proposing soon for NASA accomplishment. First, there must be adequate research effort on space technology problems. Then there must be development and use of unmanned

vehicles capable of carrying the necessary scientific data-gathering apparatus. Finally, there must be development and orderly use of man-carrying vehicles in the exploration of our solar system.

I think I should note that these programs won't be planned for accomplishment in sequence, although I would expect, for example that the journeys of man-carrying space craft to Mars or Venus certainly will come much later than some of the other work. Rather, what I envision for NASA will be essentially a three-part, comprehensive program, with progress being made in all three areas, as rapidly as the new knowledge is acquired.

One of the projects we would like to begin as quickly as possible would be development of a satellite capable of carrying, in orbit, an astronomical telescope and the auxiliary television equipment necessary to send to earth the pictures taken through the scope. To be able to observe the stars and the galaxies from a point in space where there would be none of the distortions caused by our atmosphere would enable astronomers to gather a wealth of new information about our universe.

As the more oratorically inclined scientist put it, the earth is a blanket that cuts off part of our view. It is like seeing in black and white. When we get outside of our atmosphere we can see the world in full color.

It is possible to construct a telescope of useful size, together with its supporting equipment, to be carried in an orbiting satellite weighing a ton or so. Stabilization of the satellite itself will be difficult but it appears that the task is straightforward.

As we increase our space-travel capability, we will need rocket engines more powerful than those required by the ICBM. Development of these engines—and our current thinking is with respect to a rocket engine with a million pounds of thrust—is a task that NASA will need to undertake, and we will see that it is undertaken.

When it comes to man-carrying space craft, there are a number of possible design approaches that merit active study. One of the simpler concepts would make use of a shape very much like the blunt-nosed warhead of our ICBM's. Controllability of such a space craft, upon return to earth, would be only rudimentary. Another approach would use a design with wings, in appearance not unlike the pictures of the airplanes of tomorrow that we occasionally see in the Sunday supplements. If we are content to attempt recovery after landing "somewhere in the Pacific," then the simpler of these concepts will suffice. Somewhere in the Pacific is somewhat too broad. I think the area would be less than that, but it would be some hundred or more miles square. On the other hand, if we need sufficient controllability to permit landing more precisely, say within the confines of Rodgers dry lake in California, then the winged vehicle may be needed. And it is a very difficult task with a winged vehicle. It will, however, pose aerodynamic heating problems of great magnitude. Systematic studies of the various design shapes possible will be necessary using such of our research equipment as electric plasma jets and entry simulators, high-speed wind tunnels, and highly instrumented, rocket-propelled models. In addition to these problems, there are others, also very difficult, including tumbling and deceleration, that will have to be solved.

Regarding development of man-carrying space craft, I expect we shall wish to progress from the model stage to full-size automated craft which, after their practicability has been demonstrated, will have animals as their first passengers. I, for one, will be extremely reluctant to send men into space until their craft have been sufficiently proved to give them a much better than 50–50 chance to survive.

In the final analysis, the speed with which these programs are carried forward will have to be determined by the Congress. I cannot, however, refrain from the observation that in Soviet Russia a very large effort is being made to establish for that nation a position of world leadership in space exploration and space exploitation. If our own national space program is limited to actions that, comparatively speaking, are too little and too late, we can be foreclosing the future, so far as leadership by our children is concerned.

I should like to echo the thought expressed by Dr. Killian and his committee, that we should be "cautious and modest in our predictions and pronouncements about future space activities * * * and quietly bold in our execution."

I should like at this time to clarify the meaning of the word "Advisory" with respect to its significance within the name of the National Advisory Committee for Aeronautics. I think that in previous testimony there has been confusion about this point. For the past 30 years, the name of the agency has been a misnomer. The NACA is an operating agency; it is not an advising agency.

When the Congress established the NACA in 1915, one of the responsibilities assigned to the new agency was that, in addition to directing the scientific study of the problems of flight, with a view to their practical solution, and in addition to determining the problems which should be experimentally attacked, the new agency was directed to, and I quote, "discuss their solution and their application to practical questions."

For the first 10 or a dozen years, the NACA—the Committee, the NACA's board of directors if you will—was very active in the business of giving advice. For example, in 1916, it strongly recommended that the Post Office Department establish an airmail service on an experimental basis, something that was begun 2 years later when Army pilots flew the mail between Washington and New York. In 1917, acting in this advisory capacity, the Committee led in breaking the patent bottleneck that held back American aviation progress. Again, in the twenties, the Committee gave advice that resulted finally in passage of the Air Commerce Act, the "legislative cornerstone for the development of commercial aviation in America." From that time on, the NACA could and did concentrate on its prime responsibility—the conduct of aeronautical research.

During the past 30 years, the technical staff of the NACA has frequently been called upon to serve in a consulting capacity on aeronautical matters. We stand ready to consult with the military services and the industry on technical matters; we have not told other people what they should do.

For example, this past year the Air Force had the very difficult task of deciding which of two well-qualified companies should be awarded the contract to build the new Mach-three bomber (2,000 miles per hour), the WS 110–A later designated the B–70. The NACA worked very closely with each company. Each design incorporated the latest

of NACA research progress, but this was because the companies saw how to make good use of the new NACA research information rather than because the NACA told them what they should do. The NACA consulted with the Air Force throughout the year on technical questions pertaining to the supersonic bomber concept, but at no time did we advise as to the superiority of one entry compared with the other.

Since the end of World War II, the research effort of NACA has been concentrated increasingly on problems affecting missiles and spacecraft, and today, more than half of our work is in such areas. In 1952, one of our research scientists developed a "blunt-nose" concept for the design of missile warheads. This breakthrough results in as much as 99 percent of the tremendous heat produced during the reentry phase of missile flight being dissipated back into the air without entering the structure at all. The warhead design of every ICBM and IRBM in the United States today makes full use of this concept. It will be important also when spacecraft are designed capable of returning to earth.

Intensive NACA research has been done on the structural problems of more than a dozen missile projects. Similarly, NACA has done important research evaluating materials used in the nose cone of missiles, during enentry conditions, as in the case of Polaris and Jupiter. Much NACA work has been done on high-energy fuels, such as fluorine-hydrogen, for rocket motors.

NACA help has also been given on problems peculiar to specific missiles. This type of research project is undertaken by NACA at the request of the Air Force, Navy, or Army, whichever service may be sponsoring the missile that may be in trouble. For example, in early flight tests of the Jupiter, fire and explosion destroyed the missile soon after the rocket was fired. Tests in one of our large supersonic wind tunnels made possible identification of the trouble, and suggestion of the remedy. What was happening was that hot exhaust gases were eddying back up inside the rocket-engine structure where they caused fires or explosions. It was NACA research that provided the solution.

Today, the staff of the NACA, scientists, and engineers, and supporting personnel, numbers nearly 8,000. Problems of flight are studied at our research centers at Hampton, Va.; Moffett Field, Calif.; and Cleveland, Ohio; as well as at smaller field stations at Wallops Island, Va.; Edwards, Calif., and in the near future, at Sandusky, Ohio. For the past 30 years, our mission has been the doing of research. We have done much to extend the frontiers of flight. Today, in the face of the new challenges of space technology, we feel we have just begun.

In the effort to bring to you something more than words, and to give you some physical idea of what NACA is doing in two projects, we have brought into the room the balloon-like satellites which are intended to be launched into orbit sometime within the future. We have inflated a 30-inch satellite which weighs one-fourth of a pound, about 4 ounces, which can go in the Vanguard-type of satellite.

We have also brought into the room a 12-foot satellite which weighs 9 pounds which can go in the present Explorer-type satellite.

The model on the table is the model of the front end of the Explorer. You see in the base of it the same 12-foot balloon folded, of

the same dimensions as the inflated one, and with a little bottle of gas to separate it from the rest of the satellite and inflate it.

In the front end of this model is the so-called retrorocket. The idea is, when the satellite is put into the elliptical orbit, when the point fartherest from the earth is reached, the so-called apogee, to use the technique developed by Dr. von Braun, so-called "Kick in the apogee" to give it a little extra speed to maintain the greatest distance from the earth.

This particular satellite, if we succeed in getting it into orbit with the nearest point of approach about 425 miles and the apogee at 800 miles, would be expected to have a life of about 40 days.

The object of this experiment primarily was to see what the air density or air drag is at these high altitudes and a very light, large object will be retarded much more rapidly than the heavier metal satellites.

In fact, since you have in orbit also the final stage rocket which put the satellite in orbit, which slows down, very, very slowly, simple measurements on a photographic plate of the relative distance between the light balloon and the heavy rocket motor and the way that changes in time, will give you a very quick measure of what the retarding forces are at these high altitudes.

A second objective of this type of satellite is its use in the study of radio and radar communications by reflecting radio and radar waves from such an object.

We have under design a balloon of this type 100 feet in diameter, which would weigh about 75 pounds. While the 12-foot balloon can probably be seen fairly readily at dawn and dusk, the 100-foot balloon would be visible to the naked eye to everybody everywhere, so there would be a third advantage, a psychological one of putting into orbit something which everyone could see and would not be dependent on receipt of radio signals or anything else to prove that it was there.

We also brought into the room a demonstration model of an ion jet, which is in Washington for scientific exhibit at the National Academy of Science next week. There has been discussion of this kind of powerplant in previous hearings.

I again sought to make it a little more than words. In this ion jet we use ions formed from cesium vapor. The model has a little paddle wheel to show you that there is a jet.

This particular model is not suitable for space. It is operating at a pressure equivalent to an altitude of a few hundred thousand feet, but we have made paper studies of the present outlook for what could be done with ion jet motors and it runs something like this:

A motor which would develop a thrust of only 10 pounds would weigh 10 tons. This is a present estimate.

You see, even this apparatus is connected to the powerplant of the Potomac Electric Power Co.

In the satellite you don't have this available. It has to provide its own source of energy. It has to come from burning fuel in the form of jet fuel or gasoline or from nuclear energy as we develop these suitably small light powerplants of this type, or perhaps it eventually, if we don't need too much power, might come from solar energy.

But at the present estimate an ion motor would weigh about 10 tons to give you 10 pounds thrust.

This is the order of magnitude. Some studies have been made of vehicle design using such an ion motor. These are paper computations.

Of course, if you make very high jet velocities, say, you made the ions go very fast, the energy requirements are very large, you have to have a much bigger source of power.

So, such studies have shown that the acceleration that could be obtained by ion propulsion in a space vehicle might be as low as 10 to the minus 50 times gravity.

One one-hundred-thousandth of gravity. It is obvious, since to take off from the earth you have to have a force greater than the surface gravity, that an ion system is of no use in the early stages of flight. In fact, a little computation will show you it is no use at all until you get a half million miles away from the earth. You really get out well on the way toward Mars.

For this reason, we do not have any crash projects to develop ion-propulsion powerplants. They will not be needed for some time. This subject will remain in the research stage.

We, and others in the business, will try to invent new ideas that will reduce this weight for a given thrust.

You, perhaps, have also heard about the so-called use of solar power with the photon sail. Again a few simple computations will show you that for 10 pounds thrust you need a sail which has an area of 50 million square feet. That is quite a sail, and that sail will weigh 75 tons, even though it is made of very thin foil material much thinner than the foil of these balloons.

I bring this out simply to try to show something, instead of words, to show you that these ideas which men are thinking about are not something that justify jumping immediately into a program to develop engines. None of these will be of any use until we are out a half million or a million miles from the earth.

This, I think, is all of the prepared statement I wish to make, Mr. Chairman, and now I am ready for questions.

The CHAIRMAN. Dr. Dryden, you know about the statement made by Dr. von Braun that one of the projects about propelling a man into space about 150 miles and bringing him back, and you made some kind of an off-the-cuff, I assume, observation about shooting a young lady from a cannon.

Dr. DRYDEN. Yes, sir.

The CHAIRMAN. Do you want to amplify that, or clarify it, or explain it, or anything you want?

Dr. DRYDEN. I think I should amplify the statement.

The remark, of course, dealt with the problem that there were a large number—I said 200; I hope you don't ask me to write down 200—I see my friend Jim Dempsey said on television 60 projects to get a man into space. There might be 60, but I might have trouble getting 200.

I mentioned this to show the great number and variety of proposals, ranging from the very simple proposals to those of actually putting man into a satellite orbit.

The simplest experiment which has been proposed by many people, and at least two people in my own organization tried to interest me in going ahead with such a program—there have been many proposals for this simple experiment is using the boosters that will be available

very shortly to toss a man vertically upward and then to recover him by the use of parachute or equivalent device.

Now, scientifically this gives you one result. It gives a period of weightlessness for the man of a few minutes, as compared to a little less than a minute that we now get in flying airplanes in a curved path.

Conceivably, there are certain items of equipment that could be tested. This simple experiment, however, does not throw light on the most difficult and key problem of the man in space, which is getting him back from space or satellite orbit safely. In this latter case, we have to begin with a speed of about 18,000 miles per hour.

Many computations have shown, even Russian computations which we have seen have shown, that this can be accomplished without burning the vehicle up only by entering at a very flat angle, a few degrees from horizontal, coming in, and spiraling down. It is not possible to reenter the atmosphere vertically from satellite speeds or from space.

In vertical probe, the man and his container come to rest with respect to the earth, and then he falls freely and, depending on the altitude to which you propel him, he will reenter at speeds of 1,000, 2,000, or 3,000 miles per hour. These conditions are quite different from the reentry from a satellite vehicle, so that this experiment does not give you information along that line.

The estimates of cost vary. What I have said, and I don't change the statement, is that this simple experiment standing alone as an objective, to me, is not of very much greater value than the shooting of a lady from a cannon. It does give you a little scientific information at a great deal of cost. It may be justified as part of a very comprehensive program.

Dr. von Braun and General Medaris are people that I have a great deal of respect and admiration for. They have outlined a comprehensive program of space exploration with a cost estimate of a half billion to a billion dollars, as I recall it. Whether this simple experiment can be really justified as part of that more comprehensive program is something which should be studied as to whether the results obtained are worth the cost.

A simple extension of this kind of experiment tosses a man like a ballistic missile and does simulate a lower part of the recovery path of the satellite.

Although that is a somewhat more difficult problem, it might be that this is the place to begin. In any case, as I said in my statement, I think this must be preceded by a thorough testing out of the vehicle before we put the man in it.

The CHAIRMAN. No question but what they feel the same way.

Dr. DRYDEN. Yes. My statement was not directed in criticism of any specific program, but was intended to illustrate the wide variety of simple experiments, which give you little information, to much more complicated and costly experiments which give you a great deal more information.

The CHAIRMAN. Some people thought, assuming an agency were established and you were appointed the Director, the head of it, that it might indicate the state of your mind on your part where you are more wedded to the past activities of your organization than the future activities.

Dr. DRYDEN. I hope it is not so interpreted. I think the new Agency will be faced with the problem that they will have, through the Appropriations Committees of Congress, a certain amount of funds to be devoted to this effort. Then you will have to study the comprehensive programs and cost, and match the funds to what you can do to those things which will give you the most information.

The CHAIRMAN. What other research activities of the United States Government, not now a part of the NACA, might properly be combined into a high level organization to promote space developments?

Dr. DRYDEN. The only thought that we have given to this subject is in accordance with the President's instructions to study with the Department of Defense the activities that might possibly be transferred.

Now, this has not progressed far enough to really make any statement about it. Let me put it this way, Mr. McCormack: There are people engaged in these programs. They are highly competent, qualified, and technical people. I think it would be very unfortunate if the establishment of this new Agency had the effect of throwing all this into confusion, of stopping present activities.

I think the bill is written as broadly as it is in order to permit the working out of arrangements so that, for example, any group that you choose to name, Dr. Pickering or Dr. Hagen, so that the mechanism can be found to permit the utilization of those groups. In some cases, it may be by transfer to the new Agency. In other cases, it may be by transfer of funds from the new Agency to existing groups. We have not looked at the whole United States Government.

We have taken the view that space is a very large subject. I am not quite so sure that it would be wise to think that you are going to concentrate all space activities in one place. You are setting up a central coordinating agency, an agency for leadership.

I have already mentioned in my statement the Atomic Energy Commission. Certainly, we would urge to continue the development of nuclear propulsion for use in space. This is part of the function which they have. We will expect them to continue. The idea of transferring projects from the Atomic Energy Commission, for example, would not make any sense at all.

The CHAIRMAN. Why should not the two agencies be merged, NACA and AEC?

Dr. DRYDEN. Now, you are getting into a matter of very high Government policy. I am not sure that you will get any efficiency or advantage in a merger, in actual merger; both agencies are, at present, independent agencies and are coordinated by the White House. Now, whether anything is to be gained by putting them together under one name, I, personally, would doubt, although I am not speaking for the administration on this particular problem.

The CHAIRMAN. By the way, who drafted this bill?

Dr. DRYDEN. This bill was drafted in the Bureau of the Budget. Mr. Dembling, of my staff, was present at a good bit of the discussions.

The CHAIRMAN. A little bit, you say?

Dr. DRYDEN. We had an input. It was prepared by a group within the Bureau of the Budget into which NACA could put its ideas. But the bill is an administration bill and written by the President's staff.

The CHAIRMAN. How much were you consulted?

Dr. DRYDEN. On a half dozen occasions, there were discussions of various points in the bill.

The CHAIRMAN. Now, the draft from the Bureau of the Budget seeks to solve the problem of civilian control. You notice I use the words "seeks to solve the problem of civilian control." But it does not, in fact, solve the problem, does it?

Dr. DRYDEN. I do not know what you mean to imply by civilian control.

The CHAIRMAN. It does not provide for an overall national control of outer space by our Government?

Dr. DRYDEN. It does not. It reserves the military functions to the Department of Defense, and I think this is a wise decision.

The CHAIRMAN. I just want to get information, and I am glad to get your opinion.

Dr. DRYDEN. The civil side is in the new Agency.

The CHAIRMAN. And it does not solve the problem at the intertional foreign-policy level.

Dr. DRYDEN. The foreign policy of the United States is a function of the State Department. There is a brief reference, I believe, in the preamble of the bill, No. 6, one of the objectives:

> Cooperation by the United States with other nations and groups of nations in work done pursuant to this Act and in the peaceful application of the results thereof.

The CHAIRMAN. How would you carry that out, assuming you are the Director?

Dr. DRYDEN. Of course, at present, this subject of international cooperation in space is being examined at very high levels in our Government. I do not know what the mechanisms might be exactly. As I see technical cooperation in space exploration, there are several possibilities. In the first place, we are going to have to have observations all over the world. Certainly, collaboration with nations in taking observations on satellites is one form of international cooperation.

Another possibility is to join with them in programs. This covers some of the problems, and will depend very much on the nature of the political agreements that may be worked out with respect to international activities in space.

The CHAIRMAN. That is something that can be taken care of, if necessary, when we are writing the bill. Would you think about that, as to whether or not additional language is necessary in any bill we might report out?

Dr. DRYDEN. Yes, sir.

The CHAIRMAN. I did not intend to go lengthily into the subject, but simply to call it to your attention so that you and your associates might be thinking about it and give us any additional language from the benefit of your thoughts.

Dr. DRYDEN. All of the discussions have contemplated that NASA would engage in what international activities are agreed upon as a result of the activities of the other agencies in the Government charged with international relations.

The CHAIRMAN. For example, the NASA could not take a project away from the Army, or Air Force, unless the Defense Department concurred.

Dr. DRYDEN. Only with the concurrence of the Department of Defense.

The CHAIRMAN. You have no control over military activities, such as sharing information under the IGY program?

Dr. DRYDEN. I do not think this has been any problem, Mr. Chairman.

The CHAIRMAN. I am addressing my questions now to the solution of the problem of civilian control. What would you think about writing into any bill a liaison committee between any new agency established and the military and the AEC?

Dr. DRYDEN. I think that the present method of liaison works extremely well, in which representatives of the agencies on the top advisory committees and on the technical advisory committees and, in addition, we have liaison officers in the Air Force at our existing laboratories. We have many visits back and forth. Now, it is possible to organize this liaison in a very formal way. I think the present method has worked very well. I think the other method will work, also.

The CHAIRMAN. Is there authority in the bill for research in connection with space exploration, for the actual space exploration on the part of the new Agency, if established?

Dr. DRYEN. As I read the bill, that power is contained there. I do think that there is going to be a practical problem as to how many agencies are permitted to put up satellites. It certainly will be quite a job to keep track of them all.

I have already said that I think, on any experiments made, for example, with the present power boosters, probably, we would contract with Ramo-Wooldridge Corp., or to arrange with the Air Force to do the actual firings.

I would say the bill provides great flexibility in the manner of carrying this out and, certainly, it would be entirely possible to contract to private industry or anybody else to do the actual work.

The CHAIRMAN. Yesterday, Dr. Hagen expressed the doubt as to whether the language of the bill was comprehensive enough in that respect. I called his attention to the fact that I thought it was.

Dr. DRYDEN. Yes. I will have to leave this to my legal friends to decide. I thought it was.

The CHAIRMAN. I have one more question. There is a lot of opinion that this should be on a Cabinet basis, Cabinet level. What is your personal view on that, not your official view?

Dr. DRYDEN. I think there are some questions as to whether it should begin that way. I think that space exploration will start in a more modest way. Perhaps we should wait and see how it develops before we consider making it a full Cabinet department.

The CHAIRMAN. What about making it a commission of five, like the Atomic Energy Commission?

Dr. DRYDEN. I think the commission form of organization is subject to certain difficulties arising from the determination of the relative authority of the members of the commission and the lines of authority I think that, generally, people who want to work together rise above organizations, and any method of organizations can be made to work if people want to make it work.

The objective of the bill is to provide a clear and undisputed line of authority from the President to the director and the board, which,

in the present organization of NACA's executive group, is, in a bill, reduced to an advisory function. So that the object of the bill is to be sure who has the authority, who is to be held responsible. I think, with a commission form, you do have a little more difficulty along this line.

The CHAIRMAN. If the substance of this bill should be finally enacted into law, what level in relation to the President, assuming you are a Director, would that place the Director in?

Dr. DRYDEN. At the present time, the President of the United States is very much interested personally in the space program.

The CHAIRMAN. I mean by law, now.

Dr. DRYDEN. By law it means that like any other agency, an independent agency, it will be responsible to the President.

Now, the personal relationships depend on persons.

The CHAIRMAN. That is true.

Dr. DRYDEN. I don't know how you can legislate this.

The CHAIRMAN. That is true; we understand that.

Would this put such an agency on the level, for example, of the National Security Council?

Dr. DRYDEN. I think we have to clarify the meaning. At the present time, Jimmy Doolittle can go see President Eisenhower on any matter of importance to the NACA. I can go see the President if we think it is important enough to bother him about it.

In the past few years we have seen the President several times on matters regarding the NACA.

The CHAIRMAN. That is not involved in my state of mind. I just wanted to get your opinion as to the practical operation. At what level would the Agency be?

Dr. DRYDEN. Some agencies are members of the National Security Council.

The CHAIRMAN. Do you think you should be if this bill is put through with the Director?

Dr. DRYDEN. Again it depends on the importance and the level to which this Agency grows. At the present time, I am involved, or our Agency is involved, with the Security Council in this way: When a question arises which pertains to our Agency, the field of our Agency, we are called in to special committees to deal with that.

I would expect that on any question of space that the National Security Council takes up, the heads of the Agency would be brought in whether he is a member of the National Security Council, or not.

The CHAIRMAN. You want the Civil Service Classification Act waived?

Dr. DRYDEN. This is a very important question and I think I would like to say a few words about that.

The CHAIRMAN. The only reason I raise that is, What effect would that have on scientists and technicians in other activities who are covered by the Classification Act?

Dr. DRYDEN. I think in a majority of cases they would be glad to see some escape from the dilemma which the Government now faces. Because of the Government's scale, which is something like $1,500 to $2,000 a year below the market at the medium levels and very much higher than this at the top levels, the Government finds great difficulty in obtaining competent people.

The new agency would not be able to operate at all if it is going to run a contract laboratory with a private scale and to run its present institutions with the present civil-service scales.

Every one is going to go to the contract agency. It will be impossible to run this mixed organization.

What this bill proposes to do is to preserve these teams which have been built up over many years in the Government, the facilities which have been built up in the Government, to preserve that asset in the new organization.

It cannot work in the team with contract organizations of two different salary scales. At present half of our people are paid competitive compensation. Those are so-called blue-collar people, although I do not like that designation of it. Their salaries are determined by wage surveys.

We have the problem even now at the borderline where you may find a blue-collar man in what might be considered not anything like a professional position getting more than the professional people.

We are proposing the extension of this principle to the professional people and, very frankly, I would hope and I am sure there are many scientists with responsibilities in the Government who would hope this would be a forerunner of such action for all agencies.

The CHAIRMAN. I have no objection to it. In fact, I can understand it.

My questions are not from a critical angle, but I can see where if we give this privilege to the new Agency and then Dr. von Braun and Dr. Hagen and others who have scientists and classifications who are bound by the Classification Act, that it would raise some very embarrassing situations from the angle of relativity.

Dr. DRYDEN. This question, of course, has come up before. A year or two ago we were losing large numbers of capable people. We went to the Civil Service Commission. Congress had given the authority to fix salaries in periods of shortage. We got the so-called top-grade adjustment for the people in the aeronautical research categories.

There is some dislocation in other agencies but that principle has been extended into other fields. Most of the people are quite willing to see somebody pioneer in doing something about what is really a very definite handicap.

Many of the new activities in the Government are being organized under the contract system, actually persuading somebody not already in business to set up a corporation or to set up a special corporation to run the organization under contract to avoid these difficulties.

Now, conceivably, we could run our current laboratories under contract by setting up holding corporations to run them. It would cost the Government much more money and the bill as proposed attempts to set up an organization that can function with one part of it under a contract organization, the other preserving the existing teams and staff that have taken so long to build up.

The CHAIRMAN. Should not the provisions of this bill be extended right across the board?

Dr. DRYDEN. I would hope that it would be.

The CHAIRMAN. That is the thought that came to my mind.

Dr. DRYDEN. I am prepared to discuss this with the Civil Service Committee. They are interested in this particular provision and we are prepared to discuss it with them.

The CHAIRMAN. Mr. O'Brien?

Mr. O'BRIEN. Mr. Chairman, I might make an observation. It seems to be easier to send a scientist to the moon than to maneuver him around the Classification Act.

Doctor, you stated you had a series of instructions from the President and the fourth instruction was:

> To review jointly with the Department of Defense pertinent programs currently underway or planned by the Department of Defense and to be recommended to the President which of the programs should be placed under the direction of the new NASA.

Dr. DRYDEN. Yes, sir.

Mr. O'BRIEN. Then I assume in writing the bill that was covered by the statement that these activities would be directed by a civilian agency except where they may be peculiar to or primarily associated with weapons systems or military operations, in which case the agency may act in cooperation with or on behalf of the Department of Defense.

The question is this: If these activities are peculiar to or primarily associated with weapons systems or military operations, why should they not be directed by the Department of Defense and why should there be this question of acting on behalf of the Department of Defense?

Dr. DRYDEN. I think perhaps that language does not express the intent. I mentioned our cooperation with the Department of Defense on the bomber project, for example, and now the objective of this language, which may not be the best possible language, was to permit such collaboration of continue and to be done in the space field as well as in the aeronautics field.

Perhaps these words "on behalf of," which I personally did not write, is not the proper expression, but the intent was that Defense and the Agency could collaborate on military programs as well as Defense could collaborate on civilian programs.

Mr. O'BRIEN. Doctor, I have noticed testimony from you and the other distinguished gentlemen who have been here, that there is a reference to the military use of this space technology, and then each has mentioned the peaceful uses.

Dr. DRYDEN. Yes.

Mr. O'BRIEN. That is including civilian scientists as well as the military men.

But I rather get the impression that any peaceful developments would be largely a byproduct of the military exploration, sort of a fortuitous development. Am I correct in that impression?

Dr. DRYDEN. Yes; I think that there are certain "clearly recognizable peaceful uses," let us say, to borrow this term, for space. It is hard to think of any peaceful activity that the military is not concerned with at some point. I think you will see my difficulty in a moment.

Mr. O'BRIEN. I do. I have in mind such things as weather and communications.

Dr. DRYDEN. The weather and communications are the two which come very much to mind. Weather is, of course, of interest to the military as well as to the civilians. The Weather Bureau, Dr. Reichelderfer and all of us, foresee the possibility of greater improvement in weather prediction, possibly weather "control."

This is a word we use, we don't really know whether we can control the weather, but certainly weather prediction.

At the present time all we know about the weather is on land. We send up some probes and get a few observations.

Four-fifths of the land is covered with water and we get a few observations from ships and that is all.

With satellites we can look at the clouds over the whole world.

Mr. O'BRIEN. Would you say, then, that weather perhaps is the most feasible of the peaceful possibilities for early development?

Dr. DRYDEN. Communications run very, very close to this. If we can put up things 100 feet in diameter and maintain them, it looks as if very great advances in worldwide communications can be made.

Mr. O'BRIEN. That leads to my final question.

Are any of these peaceful possibilities at a stage now warranting a special project designation and appropriation, or are they to come later as a result of these over-riding military necessities?

Dr. DRYDEN. I thnk they should be started now. Let me distinguish. We first have a bit of a research job. We have not yet fired a satellite that looks at clouds. So there is the problem of the development of means. By just as soon as the means are clear, then I think we are ready to proceed.

Now, whether this activity would be carried on as a service to the Weather Bureau, whether the Weather Bureau would do it directly, is a matter for determination.

Mr. O'BRIEN. Assuming any of these things reach a feasible stage, you would more or less break loose and go into that field?

Dr. DRYDEN. Yes.

Mr. O'BRIEN. Thank you very much.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. Dr. Dryden, as I understand, generally you agree with the provisions set forth in the bill under consideration by the committee?

Dr. DRYDEN. Yes, sir.

Mr. NATCHER. I want to direct your attention, Dr. Dryden, to page 3 of the bill, providing for a board of 17 members.

Dr. DRYDEN. Yes, sir.

Mr. NATCHER. A great number of people have expressed opinions during the past 2 weeks and a number of witnesses before this committee, that a board composed of 17 members will not be workable, the number is too large.

How do you feel about that, Dr. Dryden?

Dr. DRYDEN. Let me point out that the board is advisory, that in the history of our own past practice we have never permitted committees to get into the administrative line and hold up actions. They are forums of people of great wisdom and experience who sort of keep us in a goldfish bowl and with whom we can discuss problems.

Now the space business has such ramifications that I do not think you can get away with les than 17 people if you want to see on there the necessary board representation.

For example, it is provided that there be eight members from Government. You certainly would want someone from the Atomic Energy Commission; you would want someone from the National Science Foundation; you would want someone from Defense. You would probably want someone from the Air Force, Army, and Navy.

You see, you are already getting into numbers.

Now let me tell you the advantage of this in a very graphic way. At present we are just beginning to put civil jet transports into operation and the Civil Aeronautics Administration has the job of regulations applying to these jet transports. So they come to us for technical assistance and advice. They would like us to fly some jet transports and make some measurements so they can put some numbers in their regulations.

In a meeting that just came up General LeMay was sitting in for General Wright as a member of the NACA Executive Committee and in 5 minutes he had arranged for the loan of a jet tanker for the experiments in which the CAA was interested.

This is the kind of direct action you get from having the proper kind of Government membership on your advisory committees. You can shortcircuit an awfully lot of negotiations.

Take the other membership that has always been on the NACA, the president of the National Academy of Sciences, in fact, top scientific people generally. We have had men of considerable distinction in the aeronautical field. Space is going to require propulsion people; people concerned with vehicles, people concerned with electronics, people concerned with medicine.

To my mind it is necessary to have this number in order to have people who can reflect the points of view of the various disciplines that are concerned with space.

I should like to emphasize again, as the bill provides, these are advisory. It does not say that actions are channeled, we do not now channel administrative actions through advisory committees. We think we know how to use the advisory committees to good advantage.

For my part I support this completely. In fact, I personally have felt that maybe the committee was not quite strong enough in that they are not a policy-fixing body.

The CHAIRMAN. You mean the board of 17?

Dr. DRYDEN. Yes. At the present the NACA board is a policy-determining body.

The CHAIRMAN. You are under them?

Dr. DRYDEN. I am responsible to them, yes. They deal only with policy. They do not deal with detailed operations at all.

Like the board of directors of a company——

Mr. NATCHER. How many numbers do you have on them?

Dr. DRYDEN. Seventeen; the same number.

The CHAIRMAN. The theory of the new agency is to have somebody with responsibility?

Dr. DRYDEN. That is correct.

The CHAIRMAN. Your statement now is a contradiction of what you said before?

Dr. DRYDEN. No. I have said that we have had 40 years' experience with an organization which has worked extremely well. My first reaction was that I would like to see it continue the way it was. I think there is a lot to be said for this fixing of authority.

The present bill does fix the authority in one person with the advice, however, available to him of distinguished men who are competent in the various technical fields.

I think that is a good arrangement. It accomplishes the purpose of fixing the authority, but it does preserve the goldfish bowl contact, if you like, with people who know the game.

The CHAIRMAN. I am not arguing; I am inquiring.

All right, Mr. Natcher.

Mr. NATCHER. Dr. Dryden, the bill further provides that the director shall be appointed by the President and confirmed by the Senate. What type of individual should the director of this particular agency be, Dr. Dryden?

Dr. DRYDEN. I think, first of all, he has to be a pretty good administrator to run this complicated show with relations with Defense, with contracting agencies, with people within Government laboratories, with scientists in the country. It is quite a team here that we must use in our country to get this job done.

You cannot isolate a bunch of people and have them do it all. He must know something about the subject.

I am not in favor of managers who do not know anything about the thing which they manage. So you have to find people with both qualities. They may have started life as managers and learned science and technology, or they may have started life as scientists and learned administration.

I think these are the two sources of such people, but they must have competence on both sides. Those are the principal qualifications.

Mr. NATCHER. Would you recommend, Dr. Dryden, that the director be a scientist?

Dr. DRYDEN. Not if he is only a scientist. I have tried to make this very clear.

Mr. NATCHER. In other words, he must have administrative ability?

Dr. DRYDEN. He must have administrative ability as well; yes, sir.

Mr. NATCHER. Do you agree with Admiral Rickover's statement concerning the qualifications of a director; he should be a right good politician? How does that sound to you, Dr. Dryden?

Dr. DRYDEN. Well, I use the word "public relations," or something of the kind, not only to deal with Congress, but many other different kinds of people.

By the way, may I go on to say that I think the attempt to use a political solution of detailed technical questions is wrong. I think that politicians or statesmen, as I prefer to say it, do have the responsibility for making decisions which involve other factors. This is a thing which we have learned.

I mentioned the collaboration with the Air Force. The decision as to what contractor should build a vehicle involves a great deal more than scientific or technical considerations.

You gentlemen have to deal with many more aspects than the purely technical ones.

Mr. NATCHER. You point out in your statement that the NACA is an operating agency and it is not an advisory agency.

Dr. DRYDEN. That is correct.

Mr. NATCHER. And further, it was established, of course, in 1916. Now, Dr. Dryden, do you not have suggestions today in your own mind as to provisions for bettering the present NACA organization from the standpoint of organization and authority that are not presently a part of the law that controls NACA?

Dr. DRYDEN. Yes, I think that the bill which is before you is very much broader than the law which relates to the present NACA.

Mr. NATCHER. You think that the present NACA would function much better if they were operating under a similar bill as the one that has been presented to the committee?

Dr. DRYDEN. Yes.

Let me be a little more specific about it. Our past activities have been essentially research activities, applied research activities. This bill puts us into two new fields for the existing NACA. One is hardware development.

We at present make no contracts with anybody to build airplanes or missiles. This would put us in the business of making contracts with industry to build certain types of vehicles for us.

The other is the area of rather large operations. To do this, the internal structure, the structure below the director, must be changed. We must go through our organization and make changes in the organization. That is not giving the space job to NACA. It is building a new agency, preserving the staff facilities and values of the present NACA and giving it very much broader authority than it now has and much greater flexibility in operation.

Mr. NATCHER. Mr. Dryden, I thank you.

The CHAIRMAN. Mr. Sisk.

Mr. SISK. Dr. Dryden, I would like to pursue a little bit further this organizational setup.

Do I understand that you have taken a position that you favor the proposed 17-man board of this bill before us?

Dr. DRYDEN. I do.

Mr. SISK. You would do that as opposed to, for example, a 3- or 5-man commission?

Dr. DRYDEN. I would.

Mr. SISK. In your opinion, Dr. Dryden, what would be the difference in lag time between the determination of a policy or the expediting of a program? Do you feel that a large group of this type, and of course, I believe in your statement you mentioned a group in your present operation of some 500 people.

As I recall, I believe you mentioned an occasion where meetings, certain meetings, were held, discussions that occurred with reference to a particular program in 1952, and I think finally contracts were let in 1955.

I appreciate the things that had to occur there. Yet at the same time, do you feel that our desire to expedite some of these problems is due to, let us say, political necessity, and understand, I am not speaking in the narrow partisan sense, but the world situation, would put too great a stress on a group of this kind?

Dr. DRYDEN. I think this group does not make the determination that you are speaking of. Perhaps again I should make it clear what such a body does.

They are a group of kibitzers, if you like. The Director has full power to make decisions. He does not wait for the Board to meet; he goes ahead and acts.

However, these people look at what he is doing. If they support what he is doing they render the very valuable service of people not a party to the decision coming to you gentlemen, going to the Director

of the Budget and supporting the Director in the activities that are undertaken.

By the same token, they could go and criticize. But the possible advantages we have seen in a board are that if you have a sound and sensible program, these men of affairs whose words carry great weight in the council of people on the outside have been extremely valuable.

If I present the budget to the Director of the Bureau of the Budget, I am selfishly interested, say, in building up the agency. If General Doolittle comes in from outside, who is not dependent on this for his living at all, and has looked into the matter and makes a statement to the Director of the Bureau of the Budget, it carries a weight which is very different from that of the Director.

Maybe it should not, but it is true. I think the same is true of Congress.

Mr. SISK. I appreciate that, Dr. Dryden. Of course, I think certainly we want to take full advantage of the advice and the information that we could get from, let us say, a sizable group of people, but, at the same time, it seems to me that it is important, if we propose to move ahead with any rapidity, that we have a group, and it seems to me the smaller it is, the more expeditiously it can act, that can make the decisions and have the power to do that and eliminate this logrolling that might occur and a lackadaisical attitude. Maybe that does not exist.

Dr. DRYDEN. I think you are confusing this with the way in which some other agencies would operate. The director and his staff would have the power. There is no power of decisions in the hands of the board.

You do not wait for a board to pass on everything. You do not take contracts to the board to discuss or for signature.

The board, in this case, is looking at the highly technical operations of the agency and are giving the reaction which they are familiar with, of people they associate with every day, and this is useful for guidance.

But it is not a control. They do not take votes in such advisory committees because they do not have any power of enforcing this vote.

You discuss and get different points of view.

In this agency the director will make the decisions, or he may have made the decision before and he would tell them what he had done as a matter of information, but these committees are not in the administrative side at all.

Mr. SISK. In other words, you proposed a single director who actually has full authority, he actually becomes a czar, so to speak, and these other gentlemen are more or less in an advisory capacity?

Dr. DRYDEN. They are a source of protection to you and everybody else—that he does not become an irrational, unsound czar, because they are in a position to observe.

They have access to everything that goes on and can make a noise about it if this man gets off base.

I think this is what the bill intends to provide.

Mr. SISK. Do you think that the AEC has done a pretty good job?

Dr. DRYDEN. I think the AEC has done a pretty good job. As I said before, it is an association of people concerned rather than the

organizational chart, which determines the efficiency of an organization.

Mr. SISK. To what extent do you think we are fully utilizing our capabilities so far as scientific engineering knowledge and know-how in this country is concerned, at the present time?

Dr. DRYDEN. I know very few scientists or engineers who are unemployed. There are some.

Mr. SISK. Now, the fact of their unemployment I would question. I mean to what extent are we utilizing their capabilities in the programs in which we are most interested at the moment?

Dr. DRYDEN. I think we are utilizing them very effectively.

May I say what the problem is? Everybody in this country wants to work on space. Every engineer would like to be in this field. My office is filled with letters from people who want to join this new agency.

The popular subject is one which attracts. Now, we cannot possibly support all the people in this country who would like to work on space, all the companies, all the scientists and engineers. There are other jobs that have to be done.

Now, I think there is plenty for people to do and I think as far as the present programs are concerned we are using people pretty effectively.

Mr. SISK. The reason, of course, for my asking the question is that this has been a well-discussed question throughout these hearings because there are differences of opinion as to the extent to which we are utilizing our engineering capabilities.

Do you feel that our capabilities are on a par with other nations on the earth today?

Dr. DRYDEN. Yes. I think what has been under discussion is any specific situation. You will find on occasions a certain line of work has run out and new work has not come in, a little unsettled condition at such a time, but I think we are using our people on the whole very effectively.

Mr. SISK. And you think they are fully up to a par, or ahead of, any other country in the world?

Dr. DRYDEN. So far as the quality of the people are concerned, the abilities of the people, yes.

Mr. SISK. And under the proposed legislation we can fully utilize our capabilities engineeringly and scientifically?

Dr. DRYDEN. As far as legislation goes. Of course, the question of right and what to do, depends on appropriations as well as the legislative authorizations.

Mr. SISK. I think that is all, Mr. Chairman.

The CHAIRMAN. Mr. McDonough.

Mr. MCDONOUGH. Dr. Dryden, I was interested in your statement a moment ago concerning the weather observation possibilities of satellites.

Assuming that we had the facilities for such a satellite to observe weather conditions, just how can we put that information to useful purpose here? What can we do about it? We know a storm is coming; we know it is going to rain.

Dr. DRYDEN. The immediate benefit would be in weather predictions, at the present time, especially in the western part of our country and out in the Pacific there are few stations.

As I understand it, I am not a professional meteorologist, but from ordinary pictures of clouds the major storms can be recognized and followed from hour to hour.

A satellite, depending on the altitude, goes around every 1½ or 2 hours, and you can keep a continuous record of where the storms are and how they move.

The first benefit would be in prediction. Now, all of the ideas that we will control weather rest upon the idea that first we will understand weather, what makes it, and one difficulty in meteorology now is that we have a theory, it is difficult to get enough observations to verify and check them.

We believe that the more detailed observations this will provide over the whole world will lead to a better understanding of what it is that produces storms and how they move.

Then we are thinking of course, hopefully, that we will be able to do something about the weather if we understand how it arises.

Mr. KEATING. In California, that is? That is where they need the thing most.

Mr. McDONOUGH. On the Pacific coast. We have no problems of weather in California.

What about communications now, the practical use of transmitting communications worldwide by satellite? Can you give us an idea of how that can be practically done?

Dr. DRYDEN. First the approach will undoubtedly be the one of using satellites as reflectors. In other words, you direct a radio wave to the satellite. It then is reflected around the horizon.

A great deal of communication today is line of sight, limited by the distance you can see, and it is possible to do a great deal merely by reflection.

Now, looking further into the future, we see the possibility of having relay stations, that is stations which receive and retransmit. In theory at least, you could send a message, so to speak, to this receiver while it is overhead, store it up, and when it gets around over some other station halfway around the world, it retransmits the message down to that station.

Now, this, of course, is far into the future because it takes power. At the present time the only thing we put up in a satellite is battery power or a very small amount of solar power and this transmitter will not be very much good if it lasts only a few weeks.

But later in the future we see the possibility of active relay stations.

Mr. McDONOUGH. The bill under the declaration of policy states in No. 6:

> Cooperation by the United States with other nations and groups of nations in work done pursuant to this act and in the peaceful application of the results thereof.

Do you think under that part of the declaration of policy that we should attempt to enter into a cooperative plan with Russia to send a man to the moon and thereby expedite that action?

Dr. DRYDEN. I do not know whether such an agreement can be worked out, or not. This is a matter of diplomatic policy which is far outside of my own knowledge.

I think that the American people generally would like to put space on a peaceful basis and to have all nations cooperate in exploiting

it. I just do not know whether this is a possible thing, or not. It is at the present moment very difficult to divorce space activities from military activities. We are using boosters which come from the military ballistic missiles program, the Russians are doing the same.

Now, whether under those circumstances you can get a peaceful collaboration or not, I am just not sure.

Mr. McDONOUGH. Do you agree with the statement yesterday by Dr. Hagen that there is a danger of collisions of satellites if we put too many of them into outer space?

Dr. DRYDEN. There is a lot of room in outer space. I think the chances are pretty small. I do not foresee this to be a great problem for a long time to come.

Mr. McDONOUGH. The statement later was made that if we had more of them operating it would be easier to track them than it would be to have 1 or 2 and, therefore, the information we would obtain from them would be greater.

Dr. DRYDEN. The more you have up there sending data, the more data you can get. I don't quite see why the more you have the easier it will be to track them. I would think that the more you have the harder it is.

The CHAIRMAN. Mr. Fulton.

Mr. FULTON. Glad to see you here, Doctor.

On the bill on page 2, the question comes up as to the division between civilian approach to space and the military aproach to space. On line 4 it stated that:

> The Congress further declares that such activities should be directed by a civilian agency exercising control over aeronautical and space research sponsored by the United States.

And then on line 7, it says:

> Except insofar as such activities may be peculiar to or primarily associated with weapons systems or military operations, in which case the agency may act in cooperation with, or on behalf of the Department of Defense.

My question is this: Why not have a civilian agency or a department that has charge of all space activities, that is, both activities for peaceful development as well as military activities.

Why divide them down the middle like this, as this legislation proposes?

Dr. DRYDEN. I believe that the primary reason for making such a division is to essentially emphasize the desire of our country to promote the peaceful uses of space, to be in a position perhaps where the military classification problem does not arise quite so seriously.

Mr. McDONOUGH. Do you not think that a United States space agency should work on an overall United States national policy for space, both military and civilian?

Dr. DRYDEN. This is a policy question, of course, to be decided. My own opinion is that when you divorce military research and development, particularly hardware development from the military, that you lose.

I am not commenting on the organization within the Defense Department. There are arguments for separating within the Defense Department, procurement from research and development, and the question is whether a civilian or military head this.

But to take the full responsibility for military research out of the military departments would, I think, be a mistake.

Mr. FULTON. I do not mean to take it out. I am talking about the setting of an overall national policy for space. I would have the applied research be in the military, but I might ask you under this bill, which is my second question, do you thing that the restriction in this bill that provides that the Department of Defense shall have such activities as may be peculiar to or primarily associated with weapons systems or military operations limit ARPA and the Department of Defense on basic research? Is that too limiting in language?

Dr. DRYDEN. I think that there is a question of interpretation of exactly what these words mean. I believe that the intent of the administration in framing the law was to make this separation so far as space is concerned.

Of course, basic research, the difficulty I have with answering the question on basic research, is that most of the basic research I know has very wide application.

It is very difficult to say that this work on high-temperature materials is done for space.

Mr. FULTON. You do not think that this language is intended to be limiting?

Dr. DRYDEN. I don't think it is intended to limit the Department of Defense in doing the basic research appropriate to its mission.

Mr. FULTON. Would you have your agency, or its counsel, submit more appropriate language.

May I ask a question on the chart of the NACA organization. You are the director and Dr. Crowley is the associate director?

Dr. DRYDEN. Yes.

(Letter in answer to above request is attached.)

NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS,
Washington, D. C., May 23, 1958.

HON. JOHN W. McCORMACK,
Chairman, Select Committee on Astronautics and Space Exploration, House of Representatives, Washington, D. C.

DEAR MR. McCORMACK: During the hearings before the Select Committee on Astronautics and Space Exploration, language distinguishing the military from the civilian space programs was requested to be submitted for the record (see page 968 of the transcript).

In connection therewith, we suggest that, on page 2 of H. R. 11881, lines 9 and 10, the words "in which case the Agency may act in cooperation with, or on behalf of, the Department of Defense" should be stricken and the following words inserted in lieu thereof: "in the case of which activities the Department of Defense shall be responsible."

Sincerely,

PAUL G. DEMBLING, *General Counsel.*

Mr. FULTON. Then you have three assistant directors for research, I believe?

Dr. DRYDEN. Aerodynamics, propulsion, and structures; yes.

Mr. FULTON. Dr. Rhode is on structures, Dr. Abbott is on aerodynamics, and Dr. Rothrock is on propulsion.

Dr. DRYDEN. Yes, sir.

Mr. FULTON. If you will look at the chart you submitted, it does not have on the five categories of research programs how they fall in organization.

Would you resubmit a chart showing how it falls into the various fields of Dr. Rhode, Dr. Abbott, and Dr. Rothrock on these research programs?

May I go further. I do not see on these research programs any program at all for research study or development on photon or light propulsion.

As you know, I have been interested in that. I just have not picked that up. I would like to have a statement in the record on that.

Then on your ion rocket propulsion development, I feel that you should give a further statement because having heard you speak of the lack of practicality, there are those of us who disagree with you.

If I direct your mind to two other factors, the factor that makes the ion propulsion system so good is that while the original rate of acceleration is low, it keeps on continuing. So how long would your engine of ion propulsion type be intended to run in terms of years, and then will you please give us the rate of added acceleration during that time to give us the speed it would build up to?

Likewise, would you tell us how many materials are discharged so that we can see how the acceleration would go faster the more fuel was discharged?

Dr. DRYDEN. Yes. You can, of course, do this with a great many things.

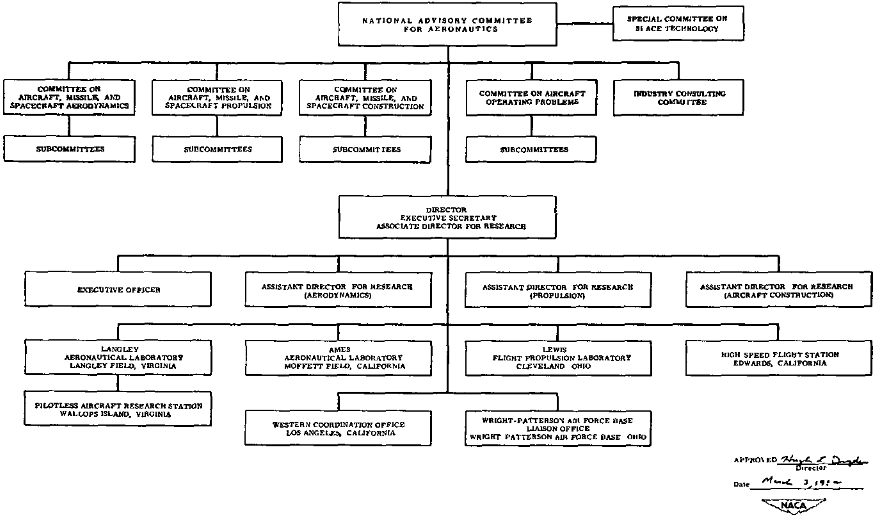
Mr. FULTON. If you will submit that for the record.

Dr. DRYDEN. All right.

(The material referred to is as follows:)

ORGANIZATION CHART

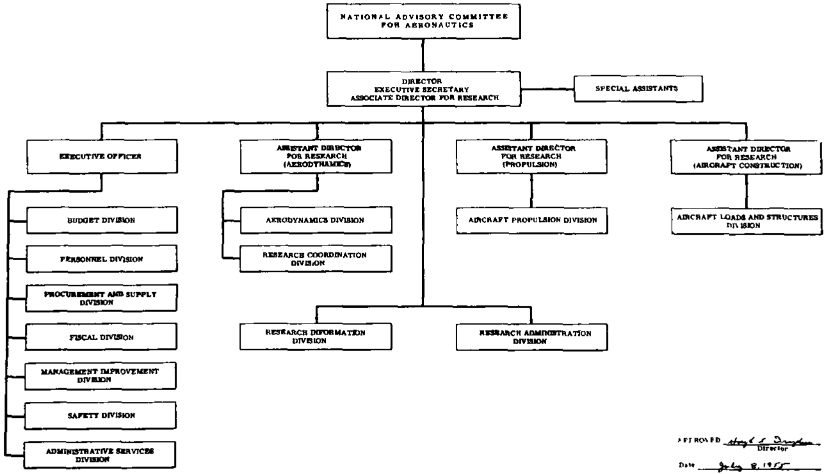
NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS



ORGANIZATION CHART

NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS

NACA HEADQUARTERS, WASHINGTON, D C



APPROVED Hugh L. Dryden
Director

Date July 8, 1955

NACA

General Statement on NACA Ion Rocket Investigation

The ion jet is a useful propulsion system where gravitational forces are extremely small or are largely canceled out by centrifugal force. This is due to the very low thrust-to-weight ratio, i. e., 10^{-4}, of these engines. The ion jet must generate ions and then accelerate them to very high velocities, i. e., a range of 64,000 to 640,000 feet per second. Since this is done electrically, one must study methods of producing ions and intense magnetic fields and perhaps equally important, methods of producing high electrical power for a minimum weight.

The NACA has been investigating several possible ion sources, such as cesium, rubidium, and potassium, seeking a system that will require the least amount of energy to generate ions with a high level of reliability and ease of control. Ionization methods such as the electric arc, electric resistance heating, and the catalytic effects of surfaces are under study.

Studies of the means of accelerating particles involve the production and use of magnetic and electromagnetic fields of high concentration, and the use of high-velocity particle bombardment. The NACA is conducting both analytical and experimental programs on ion and plasma acceleration with the objective of finding systems of minimum weight and high reliability.

As a guide for this work, we have studied analytically the requirements for ion rockets in terms of thrust, fuel required, vehicle size, speed, and control. Work of this nature was reported at NACA's Annual Flight Propulsion Conference in November 1957.

ION ROCKET

The ion rocket will generate many times less thrust (measured in pounds) than its own weight. The ratio of 10 pounds thrust to 10 tons weight to illustrate this point has been used. A photon rocket behaves similarly. However, its calculated thrust-to-weight ratio will be on the order of one-tenth of a pound thrust for each 10 tons of weight. Consequently, both engine types are useful propulsion devices only in those cases where the gravitational forces that must be opposed are less than this ratio. Under these conditions, a very small thrust will accelerate a vehicle. However, the smaller the thrust the longer the time needed to reach a given speed. The following table gives several examples:

Increase in vehicle speed for several types of rocket engines operating continuously for periods up to 1 year

Increase in speed (ft /sec) after—	Chemical rocket	Ion rocket	Photon rocket
1 minute operation	16,000		
3 months operation		3,900	39
6 months operation		7,800	78
9 months operation		11,700	117
12 months operation		15,600	156

For travel to Mars or Venus, speed increases on the order of 12,000 ft.-sec. are needed, assuming that one starts from an Earth satellite. The operating times of the ion rocket engine will be on the order of 2 to 3 years for a round trip. The photon machine will have to run much longer to produce an equal increase in velocity.

The amount of fuel consumed or discharged by the engine will vary with the time the engine is running. The following table gives several values of the discharge rate:

Fuel discharge rate for two types of rocket engine

Engine:	*Fuel discharge, lbs.-sec.*
Ion rocket	0.0013
Chemical rocket	4,500

From the above, one may conclude that any of the three engine types can be used for space missions starting from a satellite in orbit around the earth. If a chemical rocket is used, a very heavy vehicle will result. If an ion rocket is used, a lighter vehicle is possible to carry the same payload, but the travel time involved may be considerably longer. A photon rocket would significantly increase the travel time without much further reduction in weight.

A considerable background of research information has been accumulated for the chemical rocket over the last 20 years. Much more remains to be obtained. However, enough is known so that the areas where a major effort will pay off, and the extent of benefits to be gained are fairly well defined. Consequently, it is logical to plan hardware development in anticipation of research results.

In contrast to the chemical rocket, the ion rocket is in the very early stages of its growth cycle. Very little research information is available. One can only speculate as to what are the most promising and practical types of ion rockets. It is not certain that the performance figures so widely quoted can be achieved. However, the potential usefulness of the ion rocket requires that our research programs be accelerated at top speed to verify or disprove our theories. To this end, NACA is building research hardware such as ion generators, electric and magnetic accelerators, calculating the overall performance of a number of possible fuels, and evaluating the best means of producing electrical power. There is no question that ion rockets can be built. The question is, which types and designs are worth accelerating.

NACA PATENT RULES AND REGULATIONS

Executive Order 10096, issued January 23, 1950, provided for a uniform patent policy for the Government with respect to inventions made by Government employees, and for the administration of such policy. It directed each Government agency to promulgate whatever regulations were necessary to effectuate the order. In compliance with this directive the NACA regulations presently in effect were formulated. A copy of these regulations, issued on October 1, 1951, and entitled "Rules and Regulations Relating to Patentable Inventions of Employees of the National Advisory Committee for Aeronautics," is attached. The President, in Executive Order 10096, named the NACA as one of 10 Government agencies having representation on the Government Patents Board, established by that order.

NACA regulations require that all employee inventions be reported, with full information concerning the circumstances under which they were made. If patent protection is deemed advisable and a prior art search confirms the existence of patentable novelty, a determination regarding the disposition of the rights to the invention is made by NACA, in accordance with the provisions of the Executive order. If title, or all rights are to be left with the inventor, the concurrence of the Chairman of the Government Patents Board must be obtained. The employee may appeal to the Chairman of the Government Patents Board from a decision made by NACA. The decision of the Chairman upon any such appeal is final.

Mr. FULTON. Then on gravity, of course, you told us it weighs 75 tons. I imagine that is at sea level. But, for example, if you took a ton and put it out, say, 12,000 miles, it would weigh how much, about one-sixteenth as much? And if you took it out about 20,000 miles a ton would weigh only a hundred pounds.

Dr. DRYDEN. Yes, if you carry it out to a half million miles it will weigh only one one-thousandth as much and it is only there that your ion motor gives you enough thrust to do anything.

Mr. FULTON. Then your 75 tons is 150,000 pounds and it weighs one hundred thousandth of that, so it only weighs a pound and a half.

Dr. DRYDEN. That is right.

Mr. FULTON. So that really when you are getting ionic propulsion and you talk about getting 10 pounds thrust, that is really a ratio of about 6 or 7 to 1 thrust——

Dr. DRYDEN. I must say I do not follow you. The mass is still the same which you have to accelerate.

Mr. FULTON. Ten pounds of thrust and it only weighs a pound and a half. That is, you divided the pound and a half into the 10 pounds thrust and you have 10 pounds pushing a pound and a half.

I think you had better look into it again. I think that is pretty good.

Dr. DRYDEN. I am sorry; the mass is still a hundred tons and it takes the same force to change its speed.

Mr. FULTON. Yes, but you have not commented on the fact that with the continuous exertion of 10 pounds of thrust over a period of years you get a continuous rate of acceleration which builds up into tremendous leads; is that not right?

Dr. DRYDEN. That is true. In this example I have given you, you use a ton of cesium every 47 days. This is a material you have to eject.

Mr. FULTON. All right. Cesium is a very heavy material. I think its molecular weight is 100 times hydrogen——

Mr. McDONOUGH. 137 times.

Mr. FULTON. 137 times.

Dr. DRYDEN. You reduce the mass when the thrust goes down. I think this is a highly technical question.

Mr. FULTON. The question we are asking is this: Why put it on a secondary level when we are talking about going out into space in the planetary system and when we have a danger in this country of the moon being used as a satellite?

Dr. DRYDEN. I do not think I said on the secondary. I said we are not prepared to undertake a hardware development.

In the first place, we have to get the capability of putting hundreds of tons into space before this comes in and this is going to take a few years. That was the only point.

We are continuing on a research basis. We are building a larger one and operating it under conditions in which it will operate in space, but we are not making a development contract with industry to develop an engine.

Mr. McDONOUGH. Will you yield at that point?

Mr. FULTON. Yes.

Mr. McDONOUGH. On the question of the fuel unit, cesium as against the possibility of photon energy, which of the two could you put into space in the shortest period of time beginning from now?

Dr. DRYDEN. I think the ion is much closer because the photon one takes such enormous areas of reflecting surface that the problems of being able to make this and getting it fully expanded and so on is going to be very difficult.

Mr. McDONOUGH. So the ion would be the quicker of the two?

Dr. DRYDEN. The ion is shorter in the time scale, yes.

Mr. FULTON. My request is that I would like to have some Government agency take the official responsibility for an official glossary or dictionary of scientific terms in the space field, as well as in the missile and satellite areas.

Now, we have the United States Information Agency already working on one, the United States Air Force has put one out, I understand. So I would request that your agency or in cooperation with other agencies, develop a program for an official United States glossary or dictionary, terms, phrases, or words that are referred to.

Likewise, I would like to know what the incorrect usages are and the obsolete usages and apply it to both basic and applied science on both the civilian and military fields.

I think that is broad enough. If this could be done I would like it to be done in conjunction with the American Rocket Society, your own good agency, the International Astronautical Federation, the National Science Foundation, the American Academy of Science.

25973—58——29

Dr. DRYDEN. We are just completing just a glossary for aeronautics that has taken us 3 or 4 years to do. So maybe you have saved this man's job.

Mr. FULTON. Also, I would like the American Research Council to be in on it. The Advisory Committee on Aeronautics ought to be in on it, also. The colleges, the companies, the research laboratories that you have been working with should be in on it.

I should say that the American Medical Society as well as the American Bar Association.

Dr. DRYDEN. The usual technique is to circulate proposed definitions to most of the agencies you have named, that is why it takes several years to do it.

Mr. FULTON. Yes, but the trouble is that we have no official United States governmental recognized dictionary or glossary of terms in the space field at this time and many agencies are working on it without proper correlation, so I think your agency should adopt the program, or some agency should take the correlation of it for everybody, maybe the United States Information Agency.

Dr. DRYDEN. I would agree that the NASA should do this job. We have done it in the aeronautics field and I think it could be done in this field.

Mr. FULTON. Now, it has been rumored officially that ARPA has 10 times more practical programs on the shelves ready to go than they have money for.

First, is that true, and second, do you recommend going further on many of these programs than has been contemplated?

To me your recommendations for money are very short of the necessities to defend this country, and to insure our security.

Dr. DRYDEN. These are the administration recommendations, sir.

Mr. FULTON. For example, the various agencies have received $500,000 for the year to study the million-pound-thrust engine.

Dr. DRYDEN. That is far too small.

Mr. FULTON. That is what I am coming up with.

How much do you think the million-pound-thrust engine will cost to develop overall?

Dr. DRYDEN. It probably would cost, depending on what stage you are thinking of, certainly hundreds of millions, perhaps of the order of $500 million.

Mr. FULTON. So at the rate of $500,000 a year for study it will take you a thousand years?

Dr. DRYDEN. So far these are only paper studies.

Mr. FULTON. What order of magnitude should we step it up to get it on a crash program?

Dr. DRYDEN. Several million dollars.

Mr. FULTON. 15 or 20 or 25 million dollars?

Dr. DRYDEN. If the total for space is $100 million, we cannot do that.

Mr. FULTON. You see, I am trying to get what we should do, not what the limiting of the ceiling is. I want to get out into space and maybe the figures will require it.

Dr. DRYDEN. I have not had access to contract estimates of what they will require to do this in the time periods.

Mr. FULTON. As part of the buildup of the program to the million-pound-thrust engine, you are probably going to take up construction of a third-of-a-million-pound-thrust engine.

Dr. DRYDEN. I don't know whether this is really necessary, or not.

Mr. FULTON. There has been testimony that that would cost in the neighborhood of $50 million as an overall program of construction.

Dr. DRYDEN. I think that is too low.

Mr. FULTON. What would your figure be?

Dr. DRYDEN. I would want to get the opinion of the contractors who are experienced in such things.

Mr. FULTON. I had asked this question of Dr. Hagen who is one of the heads of Navy research. The question was given to me as a Navy lieutenant on an examination for promotion. He was not, unfortunately, able to answer it.

Could you tell me now on the same question, suppose you have a space vehicle or missile where the thrust equaled the drag and the gravity equaled the lift. What is that vehicle or missile doing? Where is it?

Dr. DRYDEN. It sounds like a missile in the atmosphere because there is not any lift in outer space.

Mr. FULTON. Yes, but is it standing still? Is it moving?

Dr. DRYDEN. It can be moving at any speed if the lift is equal to the weight and the thrust is equal to the drag. It can be going anywhere at any speed.

Fr. FULTON. Could it not be inconstant, unaccelerated flight?

Dr. DRYDEN. Yes, horizontal flight, but the only place to do that is in the atmosphere.

Mr. FULTON. Or could it not be at the point of stall for an airplane engine that has been climbing?

Dr. DRYDEN. I do not think so.

Mr. FULTON. Thank you. You have given me a great relief because I failed that question.

That is all, Mr. Chairman.

Mr. O'BRIEN (presiding). Mr. Keating?

Mr. KEATING. Dr. Dryden, in his message mentioned instructions which he had given to the Secretary of Defense and the Chairman of NACA to reallocate space projects. Generally what do those instructions provide for?

Dr. DRYDEN. That part of it is practically one sentence, the same thing, jointly review the programs, including the lunar probes and so on that have already been approved and make recommendations to him as to which would be in Defense and which in the new agency.

The present status of this is that Defense designated Roy Johnson and Mr. Herbert York to represent the Department of Defense in the working level discussions and I have designated some people from my staff to begin discussing with them.

Then Mr. Quarles, General Doolittle, and myself, will review what the recommendation is and transmit it to the President.

Mr. KEATING. How long have you been in consultation on this?

Dr. DRYDEN. I think we have had two meetings so far.

Mr. KEATING. You have not reached any final conclusions?

Dr. DRYDEN. No final conclusions.

Some things are quite obvious. I think it has been agreed that all of this so-called use of satellites for science would come to the new agency and agreed that the reconnaissance satellites be a military project, but we have not finished at all.

Mr. KEATING. But you have reached at least some agreements to that extent?

Dr. DRYDEN. Yes.

Mr. KEATING. Do you think that the division between the military and civilian objectives is properly provided for in this bill?

Dr. DRYDEN. I think there is a division provided there, but as to any attempt to write down the words, the only way I know to work out the meaning clearly is to take specific cases and see how they come out.

Mr. KEATING. Do you think that the further progress which you and the military people may make pursuant to the President's directive might cause you to have recommendations later as to the change in the wording in this bill?

Dr. DRYDEN. It may possibly be so. I think I can illustrate the problem. We mentioned this 1-million-pound rocket. I think it is not yet clear in which category this falls.

The question is what is the military requirement for such a rocket? If there is no military requirement for a million-pound rocket, then this belongs to the space agency.

Now, military requirements are things on which I am not an expert and I suppose the opinion of the Joint Chiefs might be asked on such a problem.

Mr. KEATING. When do you anticipate you will complete your studies with the military pursuant to the President's directive?

Dr. DRYDEN. We have been instructed to be sure it is all over with by February of next year.

Mr. KEATING. In the meantime, of course, we will be reporting out a bill here.

Dr. DRYDEN. Yes.

Mr. KEATING. Has your agency, NACA, now a present plan about developing a million-pound-thrust engine?

Dr. DRYDEN. No, we do not.

Mr. KEATING. Do you have any time schedule or anything of that kind worked out?

Dr. DRYDEN. No, sir. There have been studies made under the Defense Department. If this were said to be our responsibility we would begin at that point.

Mr. KEATING. Do you have any ideas about this bill, if this bill were passed, the coordination which would take place with other agencies like the Weather Bureau, the National Science Foundation, the Atomic Energy Commission, for instance?

Dr. DRYDEN. Yes. I believe it is contemplated that the high officials of these agencies would be represented on the advisory board.

In addition to this there would undoubtedly be need for direct consultation with working level officials on very many matters. In particular, in the use of satellites for scientific research we would propose to utilize the National Science Foundation and the National Academy of Sciences in approximately the same way that they are now cooperating in the IGY programs.

Mr. KEATING. It would not be your idea that any of their present functions would be taken over into this agency?

Dr. DRYDEN. No.

Mr. KEATING. What would be the role of private enterprise as you envisage it under this new agency?

Dr. DRYDEN. Of course, the main role of private enterprise is in the hardware aspects of the business, in building things, and we would not propose to construct the devices ourselves, but to contract for their construction, to contract for the development of items of equipment and so on.

Mr. KEATING. I think that is a very significant and important statement, Dr. Dryden.

Were you given operating authority to acquire and operate and maintain laboratories and construct them and so on, it would be your idea that the construction would take place by private enterprise?

Dr. DRYDEN. This is now done with the laboratories of NACA. All have been constructed by private builders.

Mr. KEATING. That has been your practice in the past, Dr. Dryden?

Dr. DRYDEN. Yes.

Mr. KEATING. And as you envisage it in this new agency, that is the way it would operate?

Dr. DRYDEN. Yes.

Mr. KEATING. What is the weight of that tinfoil, whatever we call it?

Dr. DRYDEN. The 12-foot satellite weighs 9 pounds.

Mr. KEATING. I mean collapsed. Is it 9 pounds?

Dr. DRYDEN. Yes.

Mr. KEATING. Does it weigh the same with air in it?

Dr. DRYDEN. Yes.

Mr. KEATING. It makes no difference?

Dr. DRYDEN. It makes no difference.

Mr. KEATING. I have one other question on the makeup of this board.

As you envisage this is to be an advisory board?

Dr. DRYDEN. That is right.

Mr. KEATING. Do you not think if that is so that we would require some change in the language on page 5? I call attention to the fact that it says:

> The board shall be consulted by the director prior to—

and then there is a long number of things which is very essential to the operation of the agency and before that it says the director shall not be appointed until the board has had a reasonable opportunity to make such recommendations.

That would seem to me, by its language, to give more than a purely advisory character to the board.

Dr. DRYDEN. Let me take them up in order. The provision of 5 (b), that the board may make recommendations to the President with respect to the appointment of the director, this is the identical language I believe in the Science Foundation bill. Its objective was to get some considered review by a number of representative people of possible candidates for the position.

The President still does not have to follow their advice, but it does insure that some consideration is given by men of broad stature to this appointment.

Now, to come to section (c), it provides that the board shall be consulted by the director. It does not say that the director has to follow their advice.

Now, I have tried to explain before why I thought it was a good thing to consult the board on policies, which was to gain their support especially in dealing with groups outside the agency.

This also provides some advice on the major organizational features.

Mr. KEATING. Are you planning to be back this afternoon, Dr. Dryden?

Dr. DRYDEN. I can be, yes.

Mr. KEATING. I would like to pursue that a little further, because I think that is an important matter for us to determine here and to consider the relative advantages of this board, or a smaller commission type.

Mr. Chairman, the second bell has rung.

Mr. O'BRIEN. Yes, that occurred to me.

We do have a rather earthy problem of answering the roll call. Could you return at 2:30?

Dr. DRYDEN. Fine.

Mr. O'BRIEN. I think we can complete your questioning shortly thereafter.

So the committee will stand in recess until 2:30 this afternoon.

(Thereupon, at 12:30 p. m., the committee was recessed, to reconvene at 2:30 p. m., of the same day.)

AFTER RECESS

(The committee reconvened at 2:30 p. m., Hon. John W. McCormack (chairman) presiding.)

The CHAIRMAN. The committee wil be in order.

STATEMENT OF DR. HUGH L. DRYDEN, DIRECTOR, NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS, ACCOMPANIED BY PAUL DEMBLING, NACA LEGAL COUNSEL—Resumed

Dr. DRYDEN. Mr. Chairman, when I was supposedly demonstrating this ion jet, I forgot we had not turned it on for the committee. So I suggest that we have the man turn it on so that you can see the paddle wheel turn.

I think from where you sit you can see a glow of light where the light strikes the pinwheel.

Mr. McDONOUGH. What does that demonstrate?

Dr. DRYDEN. This shows there is an ion jet which is striking the pinwheel. This does give a very small fraction of an ounce thrust.

The other point I was told I did not make clear is that this folded balloon in the model of the Explorer is the same balloon as the big one simply folded up.

The CHAIRMAN. Mr. Keating?

Mr. KEATING. Dr. Dryden, I had asked you about the setup of this board. The suggestion has been made here of either (*a*) a small working commission or board composed of 5 people, with a director who might perhaps be the chairman of that board, a little bit like the Atomic Energy Commission; or (*b*) a director as here provided, with a large 17-man board.

You prefer (*b*) I take it.

Dr. DRYDEN. I prefer (*b*) because, with the larger number you get representation from the various professional groups and the Government agencies concerned. A small board of 4 or 5 could only represent a very small segment.

Furthermore, I think at least in theory there is the problem of spelling out the relative responsibilities of the other members who are full time. It is not quite as direct a line of authority; you have several people full time running the agency.

Mr. KEATING. The opposition which has been expressed to this setup has been along the line of "Here is a 17-man board meeting 4 times a year, or perhaps only 4 times a year, and they could not have the intimate supervision of the operations in a manner similar to that of a smaller group."

As I understand your position, they are not supposed to.

Dr. DRYDEN. They are not supposed to do this detail. Our present board meets nominally once a month, actually about 10 times a year. They are not dealing with the details of administration.

On the other hand, the members of the board are supposed to be people who in their normal contacts know what is going on in the space field. In other words, they are either in contact with this or in Government agencies in contact with it or perhaps they have industrial connections.

This is a matter which is not spelled out in detail. The board membership is left flexible. I would expect that the objective would be to get as many different professions and points of view, as well as representation from the Government agencies, like the AEC, National Science Foundation, Defense, and so on.

Mr. KEATING. Does it not strike you that if the director, as this is set up, were required to consult with this board prior to the initiation or substantial modification of policies or programs of the agency, it might develop into a cumbersome arrangement?

Dr. DRYDEN. If you will accept my premise that the board will meet once a month, I cannot imagine policy reversals every month. Policies, I hope, are more stable things, to be changed on some mature deliberation.

As it stands, of course, the bill spells out consultation. If the matter is sufficiently urgent, the director should proceed to act in advance of any meeting of the board.

Mr. KEATING. Perhaps we should consider making the minimum times of meeting greater than they are here. It says they shall meet at least 4 times a year. You contemplate that you should like to see them meet monthly.

Dr. DRYDEN. I would like to see this number increase somewhat as a personal view. Actually, they meet about 10 times a year at present. Perhaps some number like 6 or 8 would be more appropriate.

Mr. KEATING. Dr. Dryden, I inquired of you about the directive from the President, that is, the instructions to the Secretary of Defense and you as chairman of NACA, about the reallocation of space projects.

I take it that probably that directive itself you are not at liberty now to enter into this record?

Dr. DRYDEN. I am not at liberty at the moment to enter it into the record. I can take up the question.

On this particular point, the instruction is essentially the sentence in the President's message which instructs the Department of Defense and the NACA to jointly review the projects. There is nothing more on this point in the instructions.

The next sentence is the working out of plans of cooperation with the Defense Department.

Mr. KEATING. That is what you are working on now?

Dr. DRYDEN. We are working on both aspects.

Mr. KEATING. Is there anything else in the Presidential directive which you would feel at liberty to discuss now?

Dr. DRYDEN. I can tell you the essential content of it, I think. The first instruction is to explain the bill to Congress. NACA is given the job of explaining the bill to Congress.

Second, we are supposed to work out organization plans, what changes in the organization and management structure of NACA would be needed to fit it to undertake these new responsibilities.

I think the third one is the one of review of programs, work out a cooperative plan.

I think the final one is an instruction to Defense to submit a list of the military projects. This is the essential content of it. There is a preamble which is roughly the same as in the President's message.

Mr. KEATING. There is a time limit and that time limit is what?

Dr. DRYDEN. There is a hope or expectation that the actual transfer of those who decided to go into the new agencies will be completed by February 1959. This assumes that a law is passed by Congress, and so on.

Mr. KEATING. There are some civilian activities which the military is now conducting in connection with their space program which it is contemplated would be turned over to the new agency.

Dr. DRYDEN. That is correct. In order to avoid any delay in such activities, you may recall the President approved certain projects to be conducted by ARPA so that there would be no gap waiting for Congress to act on a new agency, but in the approval of those projects it was pointed out that there would be a reconsideration when, as and if a civilian agency was established to see whether these projects would be transferred. In fact, there is general agreement that these specific projects should be transferred.

Mr. KEATING. I think that is all, Mr. Chairman.

The CHAIRMAN. Mr. Ford?

Mr. FORD. Dr. Dryden, section 9 (a) of the bill, in effect, would give NASA what we call a no-year fund authority. Will you tell us why that language is essential for the successful prosecution of this new agency's responsibility?

Dr. DRYDEN. Well, instead of the word "essential," I would say it would enable it to operate in a more efficient manner. At the present time our construction appropriations, for example, are no-year money.

We know what money is available; we can make our plans to fit the money that is available and to push them at the best possible rate. I think the idea of this is that most space projects are going to run over a relatively long period and that this will enable a somewhat more efficient administration of funds if there is no pressure, for example, that you must get rid of all your money by a certain

date; otherwise Congress will say you do not need it and take it away from you. This enables you to plan in a more orderly manner; that is the idea.

Mr. FORD. In the Defense Department appropriation bill for the three research and development organizations they have such authority.

Dr. DRYDEN. That is right.

Mr. FORD. This would simply give to the new agency identical authority.

Dr. DRYDEN. That is correct.

Mr. FORD. Does NACA have such authority at the present time?

Dr. DRYDEN. We do not, except for construction funds.

Mr. FORD. Construction, but not for research?

Dr. DRYDEN. But not for operation; that is correct. Any money unexpended goes into the Treasury.

Mr. FORD. However, this new assigned responsibility would appear to justify a change in your research funds, putting them on a no-year rather than 1-year basis.

Dr. DRYDEN. On the same basis that the military require it for their research and development activities.

Mr. FORD. If this new agency is set up on the basis of this proposed legislation, what will the relationship be between it and ARPA?

Dr. DRYDEN. As I understand the working arrangements, and this has been discussed very briefly, there will be within the Department of Defense some projects assigned to the Air Force, space projects, or at least handed to the Air Force.

I am using this only as an example, but presumably there will be Navy projects and Army projects, and there will be ARPA projects. Just as we at present work cooperatively with the Air Force on military projects, we would work cooperatively with ARPA on the projects assigned to ARPA.

As I understand it, this is the way in which this will actually operate.

Mr. FORD. In other words, the enactment of this bill and the implementation of it would not automatically bring to an end ARPA's existence?

Dr. DRYDEN. This gets to be a legal question. I understand there is a little controversy about the legal status of ARPA. There is some language which expires next February.

There is another view that no language is necessary for the President to be able to operate in this fashion.

Mr. FORD. I did not bring the point up to determine the legality one way or the other, but ARPA, whether it is set up legally or whether it is set up administratively.

Dr. DRYDEN. They will manage the administrative projects as assigned by the Secretary of Defense.

Mr. FORD. Would NASA have legal authority to make contractual arrangements with the various service research and development agencies, Army, Navy, and Air Force?

Dr. DRYDEN. Yes, sir; there is very broad authority. That is on page 8,

to use, with their consent, service, equipment, personnel and facilities, Federal and other agencies, with or without reimbursement, and on a similar basis to cooperate with other public and private agencies and instrumentalities in the use of service, equipment and facilities of the agency.

Then there is authority to transfer without reimbursement such things as technical supplies. There is authority to enter into cooperative agreements under which members of the Army, Navy, Air Force, and Marine Corps may be detailed by the appropriate Secretary for service in the performance of functions under this act to the same extent they might be assigned to the defense.

As I read this, this provides for broad authority to enter into any type of agreement, contract or whatever the particular nature of the agency that we want to use requires.

I hope that this broad authority stays in because I think it will then enable the agency to utilize the people who are now doing the work, whether they are in private industry, whether in military departments, or wherever they may be, and under conditions that can be worked out in each specific case.

Mr. FORD. You mentioned in response to a question by Mr. Keating that your current advisory board meets on an average of 10 times yearly.

Dr. DRYDEN. Yes.

Mr. FORD. For how many days do they meet?

Dr. DRYDEN. It is usually an afternoon meeting. They function very much like a board of directors of a company, concerning themselves with very broad questions and not with detailed administrative questions.

Mr. FORD. Do they give adequate time on that kind of schedule to pass judgment on the broad aspects of a program?

Dr. DRYDEN. I think so. They do receive, of course, from the various technical advisory committees, recommendations which they consider. Perhaps I might illustrate it by the way the budget process begins in NACA now.

The board fixes the general policy; they decide, "Are we to increase effort 25 percent; are we to stay level? What are the broad policy decisions to be made about the budget?"

The staff then works up the details on how many men it takes to do this, what the dollars are, and what are the supporting supplies. When that task is finished, it usually comes back to the board in summary form to see what the result of the staff work has been and there is an approval or disapproval at that point under the present arrangement.

Under the new arrangement the provision is that the board would be consulted but they would not have to approve it. In fact, the budget could be submitted in advance of submitting it to the board.

I beg your pardon. I must correct that. I believe the language says "consult prior to submitting the budget." This is usually not a problem because, as you know, the usual budget date is in September. This means at a June or July meeting we get some policies determined and the staff goes to work on the documents which are to go before the Budget Bureau.

Mr. FORD. For how many years has your current advisory board setup worked as you described it a minute ago?

Dr. DRYDEN. Forty-three years; since 1915.

Mr. FORD. NACA has had a very successful record over that period of time, using that procedure.

Dr. DRYDEN. Using this procedure. I know that some people say it cannot possibly work, but the fact is that it has worked extremely well.

The CHAIRMAN. Mr. Fulton, did you want to ask some questions?

Mr. FULTON. Yes. Should there be a provision in the legislation that when there gets to be a question whether certain facilities or equipment should be turned over by various agencies to the new space agency, that the President shall have the right to make that determination?

Dr. DRYDEN. That is in the law, perhaps not spelled quite in the language you have said.

For a period of 3 years after the effective date of this act, the agency, with the concurrence of the head of the department or agency concerned and with the approval of the President, may transfer to itself any functions (including powers, duties, activities, facilities, and parts of functions) of such department or agency or of any officer or organizational entity thereof which relate primarily to the functions of the agency as set forth in section 6 hereof. In connection with any such transfer the President may, under authority of this section or under other applicable authority, provide for appropriate transfers of records, property, civilian personnel, and funds.

The CHAIRMAN. That is a double negative, though, with the President in the second negative. In other words, it must start with the new agency; second it must be with the concurrence of the head of the department or agency, which means that the head of the department or agency has the veto; and third, with the approval of the President.

Dr. DRYDEN. Yes, sir.

Both the head of the agency and the director would be responsible to the President. I do not see anything which prevents the director of the agency taking that problem to the President if he cannot come to an agreement with the head of the agency.

The CHAIRMAN. Can you mention to this committee any precedent anywhere else for that, that kind of language?

Dr. DRYDEN. I do not know. This is a temporary thing for 3 years. It is part of the transition process. It does not go on indefinitely.

Mr. FULTON. There is the use of the word "may," which is permissive. It might be made mandatory with the word "shall."

Secondly, as the "President shall provide" might be turned into how the President might order, giving him the power to order and not a word like "provide." I agree with Mr. McCormack that it seems to leave it to the agencies.

Dr. DRYDEN. I think the President has the power and I think this language provides it. Of course, again I am not a professional lawyer.

The CHAIRMAN. Suppose Congress agrees to the transfer of some other activity like the National Science Foundation to the new agency; Congress would then have an opportunity of passing upon it which it would under any reorganization plan?

Dr. DRYDEN. I think it would apply only to those functions which pertain to space, as I read this. Now certainly Congress is free at any time to take legislative action affecting the organizational structure.

Let us get very specific. Let us take Dr. Hagen's group, which is now a naval activity. As I read this legislation as a whole, not just

this section, there are three possibilities for incorporating that activity into the new agency.

One is to leave it where it is and transfer funds to support it. The second is to transfer it into the new agency and leave it where it is and rent from the Navy whatever is necessary. The third possibility is the transfer of the agency out completely and move it somewhere else.

As I read the law, any of those three solutions could be done and it will be done with the approval not of the Secretary of the Navy, but of the Secretary of Defense, as I read this——

Mr. FULTON. Do you not feel, though, when it comes to the magnitude that Mr. McCormack has pointed out, on the agency or installation level, that when a whole fabric of productive facilities, plus personnel, is turned over, that there should be some specific method of doing it, possibly with the approval of Congress or with the reorganization plan submitted within a certain number of days?

Dr. DRYDEN. I, as an individual, certainly would have no objection to this. This is an attempt to deal with a transition situation while the new agency is being organized.

The CHAIRMAN. Any further questions?

Mr. FULTON. Would you submit a statement for the record giving the policy of your agency in the handling of patents, copyrights, chemical formulas and chemical processes?

Secondly, I would like to ask, too, the policy on handling security policies, just a general statement.

Dr. DRYDEN. Just a general statement. We, of course, have regulations which are pretty consistent with those of Defense and AEC. It is quite a collection.

(The material referred to is as follows:)

RULES AND REGULATIONS RELATING TO PATENTABLE INVENTIONS OF EMPLOYEES OF THE NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS

Attachments:

(1) Administrative Order No. 5 of the Government Patents Board approved 26 April 1951 (16 F. R. 3927).

(2) Form NAVEXOS-2374 (Rev. 4-51), Record of Invention and Instructions for Preparation thereof.

(3) Form NAVEXOS-2375 (Rev. 1-47), Disclosure of Invention.

1. *Executive Order 10096.*—By Executive Order 10096 dated 23 January 1950 (15 F. R. 389), the President established a basic Government patent policy with respect to the inventions made by employees of the Federal Government under which the Government may, under certain conditions, acquire title to inventions made by its employees, while providing for partial or complete retention of rights by employees under other conditions. Determination by a Government agency that the Government has or is to take less than full title to an invention is subject to approval by the chairman of the Government Patents Board established under this order.

2. With a view to obtaining uniform application of the policy set out in this order and uniform organization thereunder, the chairman of the Government Patents Board is authorized and directed, after consultation with the board, to formulate and submit to the President for approval such proposed rules and regulations as may be necessary or desirable to implement and effectuate the policies established. Each Government agency is also required to take all steps appropriate to effectuate the order, including the promulgation of necessary regulations which shall not be inconsistent with those approved by the President.

3 *Government Patents Board Implementing Rules and Regulations.*—On 26 April 1951 the President approved certain rules and regulations under Executive Order 10096 which have been issued as Administrative Order No. 5 of the

Government Patents Board (16 F. R. 3927), attachment (1). These rules and regulations in section 6, thereof, restate the basic Government patent policy established by the President; and in this section and certain others set forth the responsibilities of government agencies. The agency responsibilities, among others, include determination of invention, determination of rights in inventions, determination of whether patent protection will be sought in the United States, and the furnishing of certain reports.

4. *NACA Responsibilities.*—In carrying out these agency responsibilities for the Natioanl Advisory Committee for Aeronautics, NACA headquarters will be responsible for and, with the assistance of patent counsel made available by the Department of the Navy or other appropirate agency, will discharge the following functions:

(a) Determine whether the results of research, development, or other activity within the National Advisory Committee for Aeronautics constitute invention within the purview of Executive Order 10096;

(b) Determine, subject to review by the chairman of the Government Patents Board, the respective rights of the Government and of the inventor in and to any invention made by an employee of the National Advisory Committee for Aeronautics;

(c) Determine, subject to certain exceptions noted hereinafter, whether patent protection will be sought in the United States by the National Advisory Committee for Aeronautics for usch inventions, and;

(d) Furnish reports as required to the chairman of the Government Patents Board relating to the determination of rights, the taking of appeals, the filing of applications, and the issuance of patents.

DETERMINATION AND ASSERTION OF RIGHTS

5. *Conditions for Assignment.*—The National Advisory Committee for Aeronautics may require assignment of title to inventions made by its employees and to patents that may be issued on such inventions if any of the following conditions are present:

(a) If the invention was made during working hours; or

(b) If the invention was made with a contribution by the Government of facilities, equipment, materials, funds, or information, or of the time or services of other government employees on official duty; or

(c) If the invention bears a direct relation to or was made in consequence of the official duties of the inventor.

6. *Definitions of Conditions.*—In determining whether a condition set forth above was present in the making of the invention, the following definitions shall apply:

(a) Working hours shall mean time spent during either the usual working hours, overtime, or both;

(b) A contribution of facilities shall mean that the facilities were used in the making of the invention and while so used were made unavailable for other purposes;

(c) A contribution of equipment shall mean that the equipment was used in the making of the invention and was thus made unavailable for other purposes;

(d) A contribution of materials shall mean that the materials were specifically obtained and used for the purpose of making the invention and were thus rendered unavailable for other use;

(e) A contribution of funds shall mean that government funds were actually expended for the purpose of making the invention;

(f) A contribution of information shall mean that the information used in the making of the invention was available only by reason of the inventor's official duties and was obtained from sources not otherwise available;

(g) A contribution of time or services of other Government employees on official duty shall mean that their time or services were utilized during working hours as defined in (a) above;

(h) Bearing a direct relation to or made in consequence of the official duties of the inventor means that the duties to which the inventor had been assigned were such that the invention could reasonably be expected to arise therefrom.

7. *When Assignment is Required.*—When any of the conditions set forth in paragraph 5, as defined in paragraph 6, are present, the domestic rights and, in

the discretion of NACA headquarters, foreign rights in and to the invention shall belong to the Government if

(a) The conditions are equitably sufficient to justify assignment thereof by tht employee to the Government; and

(b) The Government has sufficient interest in the invention to require assignment thereof by the employee.

If it should be found that assignment is not required under (a) and (b) of this paragraph, the employee nevertheless shall be required to grant to the Government a nonexclusive, irrevocable, royalty-free license in the invention and under any patents which may issue thereon, with power to grant licenses for all governmental purposes. When none of the conditions set forth in paragraph 5, as defined in paragraph 6, are present, the entire right, title, and interest in and to the invention shall be left in the employee, subject to law.

8. *When Conditions Are Presumed.*—It is presumed that the conditions of paragraph 5, as defined in paragraph 6, are present, when the employee is employed or assigned:

(a) To invent or improve or perfect any art, machine, manufacture, design, or composition of matter;

(b) To conduct or perform research or development work, or both;

(c) To supervise, direct, coordinate, or review government financed or conducted research work, or both; or

(d) To act in a liaison capacity among governmental or nongovernmental agencies or individuals engaged in such research or development work, or both.

9. *Burden of Proof.*—Employees within the classes defined in paragraph 8 may submit evidence that will enable NACA headquarters to establish the absence of any one or more of the conditions of paragraph 5, as defined in paragraph 6, or that the conditions which are present are insufficient equitably to justify a requirement that assignment be made to the Government of the invention and any patent which may issue thereon. For employees not within the classes defined in paragraph 8, the Government must establish that the conditions of paragraph 5, as defined in paragraph 6, if present, are sufficient equitably to require an assignment to the Government of the invention and to any patent which may issue thereon.

10. *Foreign Rights*—An assignment of the foreign rights in and to the invention shall be made by the employee, upon request, whenever an assignment of the domestic rights is required. Where, however, an assignment of the domestic rights is not required, an assignment of the foreign rights in and to the invention may be made by the employee, upon request.

APPEALS AND PETITIONS

11. *Appeals.*—Any employee of the National Advisory Committee for Aeronautics who is aggrieved by a determination by NACA headquarters pursuant to paragraph 7 may obtain a review of the determination by filing, within thirty (30) days (or such longer period as the chairman of the Government Patents Board may, for good cause, fix in any case), after receiving notice of such determination, a written appeal with the chairman of the Government Patents Board and a copy of the appeal with NACA headquarters.

12. In the event of the filing of an appeal, NACA headquarters, subject to conditions of national security, shall furnish the chairman of the Board in writing, promptly upon the filing of the appeal, the information required by paragraph 7 (b) of attachment (1). The decision of the chairman of the Board upon any appeal taken pursuant to paragraph 11 shall be final.

13. *Petitions.*—In the event that NACA headquarters determines pursuant to paragraph 7 that the domestic rights in and to an invention will be left with an employee with or without a license in favor of the Government, a report of this determination is required to be submitted to the chairman of the Board for review, subject to the right of the employee, if he acquiesces in the determination, to file a petition in the event of a decision less favorable to him.

14. The chairman of the Board will review such a determination by NACA headquarters, and his decision respecting the matter shall be final, subject to the right of the employee to submit to the chairman, within thirty (30) days, (or such longer period as the chairman may, for good cause, fix in any case),

after receiving notice of such a decision, a petition for the reconsideration of the decision if it gives to the Government greater rights than the determination made by NACA headquarters A copy of any such petition must also be filed by the employee with NACA headquarters within the prescribed period.

PATENT PROTECTION

15. *General.*—NACA headquarters, upon determining that an invention has been made under the conditions specified in paragraph 5, as defined in paragraph 6, shall thereupon determine whether patent protection will be sought in the United States by the National Advisory Committee for Aeronautics for such invention. A controversy over the respective rights of the Government and of the employee in any case shall not delay the taking of any action seeking such patent protection. In cases pursuant to paragraph 7 where it is determined that the domestic rights in and to the invention are to be left with the employee, action by the National Advisory Committee for Aeronautics looking toward such patent protection shall be contingent upon the consent of the inventor.

16. *Dispute as to Rights*—Where there is a dispute as to whether the Government is to obtain an assignment of the domestic rights in and to the invention or only a license thereunder, NACA headquarters will determine whether patent protection will be sought in the United States pending the decision of the chairman of the Government Patents Board on the dispute, and, if NACA headquarters decides that an application for patent should be filed, will take such license rights as are specified in subparagraph 6 (b) (2) of attachment (1), but this shall be without prejudice to acquiring an assignment of the domestic rights in and to the invention as specified in subparagraph 6 (b) (1) of attachment (1) should the chairman of the Board so decide.

17. *Rights in the Employee*—Where, however, NACA headquarters has determined to leave the domestic rights in and to the invention with an employee subject to a license in favor of the Government and the employee acquiesces in this determination, NACA headquarters will, upon the filing of an application for patent and pending review of the determination by the chairman of the Government Patents Board, take such license rights as are specified in subparagraph 6 (b) (2) of attachment (1), without prejudice to the subsequent acquisition by the Government of the domestic rights in and to the invention as specified in subparagraph 6 (b) (1) of attachment (1), should the chairman of the Board so decide.

REPORTING OF INVENTIONS

18. *Employee Defined.*—The term "employee" as used herein means any officer or employee of the National Advisory Committee for Aeronautics, including any part-time consultant or part-time employee except when special circumstances in a specific case require a departure herefrom to meet the needs of the National Advisory Committee for Aeronautics. Such circumstances shall be reported to the chairman of the Government Patents Board and separately promulgated if approved by him.

19. *Responsibility of Employee*—

(a) Whenever an employee of the National Advisory Committee for Aeronautics conceives an idea which he believes to be of a patentable nature he shall prepare a memorandum describing in detail such idea and the means which he proposes for its reduction to practice, and shall submit it through official channels to NACA headquarters together with a formal Record of Invention and Disclosure of Invention on Forms NAVEXOS 2374 and 2375, respectively, or such other forms as may hereafter be prescribed. The memorandum shall include a statement describing the circumstances under which the invention was made, with particular regard to the conditions listed and defined in paragraphs 5 and 6, respectively, of these regulations.

(b) If a decision is reached to proceed with the procurement of a patent, the employee shall cooperate fully with patent counsel in the preparation of a patent application of such scope as will assure maximum protection of the Government's interests, and, subsequently, as may be required from time to time during the prosecution of the application, in the preparation of amendments responsive to Patent Office actions thereon

20. *Responsibility of Laboratory.*—

(a) The reporting of patentable inventions resulting from the research activities of the National Advisory Committee for Aeronautics is the joint responsibility of the supervisory personnel and the individual employee who conceives the idea upon which the invention is based. A disclosure made by an employee shall be amplified, if possible, by the comments of his supervisors, and shall be transmitted through official channels to NACA headquarters with full information concerning the inventor's employment status and work assignment at the time the invention was made, and with definite recommendations regarding the initiation of patent action, and the respective rights to be claimed for the Government and for the employee.

(b) To avoid jeopardizing the interests of the Government, the laboratory shall promptly notify NACA headquarters of any public disclosure, by publication or otherwise, of any patentable developments of its employees not already protected by United States patent or patent applications.

DETERMINATION OF INVENTION

21. *Invention Defined.*—The term "invention" as used herein means any art, machine, manufacture, design, or composition of matter or any new and useful improvement thereof, or any variety of plant, which is or may be patentable under the patent laws of the United States.

22. *When and by Whom Determined.*—NACA headquarters, with the assistance of patent counsel made available by the Department of the Navy or other appropriate agency, will be responsible for determining whether the results of research, development, or other activity within the National Advisory Committee for Aeronautics constitute invention, and where practicable, will make this determination before determining the respective rights of the Government and the employee on the basis of information furnished by the employee and the laboratory, together with such other information as may be required.

SCOPE OF REGULATIONS

23. *Inventions Covered.*—The foregoing provisions of these regulations apply to any invention made by an employee on or after 23 January 1950 and to any action taken with respect thereto, and with regard to such invention supersede the patent policy of the National Advisory Committee for Aeronautics dated 30 June 1949. As to inventions made before 23 January 1950, the respective rights of the Government and the employee will be determined under the provisions of the patent policy of the National Advisory Committee for Aeronautics approved 20 October 1944, as amended 30 June 1949.

HUGH L. DRYDEN, *Director.*

OCTOBER 1, 1951

SECURITY CLASSIFICATION

It is the policy of the NACA to classify research information if, and only if, the publication of the information would assist a potential enemy more than it would assist the United States. NACA's policy has been maximum disclosure of information consistent with national security. Much of NACA research relates to military weapons or has potential military utilization, in which case we are guided by the policies of the military services in assigning security classification.

The results of NACA classified research are made available to the interested Government agencies and military services and to appropriate Government contractors, such as manufacturers of missiles or aircraft cleared for handling classified information.

Mr. FULTON. Then I would like a listing of the matters which are now in dispute over jurisdiction with ARPA as to projects.

Dr. DRYDEN. I am unable to do that, because the negotiations have not gotten that far. In fact, ARPA does not have a specific program at this time to do it that way.

Mr. FULTON. Can you give us the current statement of the standing of negotiations with ARPA so that we can see who is doing it and how it is being done?

Dr. DRYDEN. Yes.

(The material referred to is on p. 949.)

Mr. FULTON. I also would like to have a calendar put into the record at this point of your agency's participation in the IGY and also the future calendar of how you are going to finish it; in short, by date, just a summary.

Dr. DRYDEN. We have only incidental contact at the moment with IGY.

Mr. FULTON. Yes; but I would like it summarized so that someone can look down and see by date the calendar of your activities.

Lastly, I would like to know what your relation has been, for example, with the International Civil Aviation Organization, the ICAO, under the United Nations. And, lastly, the relations that your agency may have had with Russian and satellite scientists.

Dr. DRYDEN. None whatever; I can answer that right now.

(Material referred to is as follows:)

RÉSUMÉ OF NACA SPACE RESEARCH CONTRIBUTING TO THE UNITED STATES INTERNATIONAL GEOPHYSICAL YEAR PROGRAM

The extensive and sustained effort over many years of the National Advisory Committee for Aeronautics (NACA) in pressing forward scientific knowledge of the earth's atmosphere and of flight at ever increasing altitudes into space, thereby making possible and supporting the upper atmosphere sounding rocket and the earth satellite projects of the United States International Geophysical Year program, are briefly traced as follows.

1922: NACA assembled and analyzed the existing information on the earth's atmosphere, formulating and compiling it into the standard atmosphere, and published as NACA Report No. 147.

1925: NACA extensively enlarged the standard atmosphere, publishing it as NACA Report No. 218.

1946: NACA formed the special Committee on the Upper Atmosphere, drawing together the Nation's most qualified scientists to assemble, summarize, and compile knowledge of the earth's atmosphere out to the borders of space. The results were published as NACA Technical Note 1200 and formed the foundation for the exploration of the upper atmosphere by means of sounding rockets.

After World War II, NACA has continuously furnished a technical consultant to, and rendered assistance to, the V–2 Panel, later known as The Upper Atmosphere Rocket Research Panel, and now called The Rocket and Satellite Panel, of which Dr. James A. Van Allen is the present chairman. Under this panel was coordinated the upper atmospheric research done prior to the International Geophysical Year using the V–2, and later the Aerobee and Viking rockets whose designs are based largely on numerous NACA technical reports. The development of the high-performance, solid-propellant Deacon rocket, as reported in NACA Research Memorandum L8H26, made possible the inexpensive combination rocket and balloon system, called Rockoon, used by Dr. Van Allen for cosmic ray research.

1952: NACA played a major role in developing and promulgating the first internationally adopted "Standard Atmosphere," bringing order in this field for the first time on a worldwide basis. NACA was entrusted with the compilation of this internationally used standard atmosphere in both metric and English units, and published it as NACA Report 1235.

1955: In preparation for the United States rocket and satellite programs for the International Geophysical Year, NACA furnished two members to the main

committee convened to draw up the Air Research and Development Command model atmosphere 1956, which is a preliminary extension to extreme altitudes of the International Standard Atmosphere of NACA Report 1235, that is used as a guide during the International Geophysical Year. The NACA furnished a member of the 12-man special committee appointed to formulate the detail specifications of this extension, and furnished the member who served as chairman of the Special Committee on Physical Constants.

With the organization of the United States National Committee for the International Geophysical Year, the NACA furnished two members—Dr. Hugh L. Dryden, as a member of the United States National Committee, and Mr. William J. O'Sullivan, as a member of the Technical Panel on Rocketry and as the experimenter responsible for two of the officially approved and scheduled satellite experiments furnished by NACA.

In support of the United States IGY program exploring the upper atmosphere, NACA, through its member on the Technical Panel on Rocketry, proposed both the Nike-Deacon (or Dan) and the Nike-Cajun (or Can), solid-propellent sounding rockets. These simple and relatively inexpensive vehicles made possible a great increase in the number of sounding rockets the United States is launching during the IGY without increase in cost, as well as making possible tests not capable of being performed by other rockets The NACA designed, constructed, and tested in flight these two sounding rockets, as reported in NACA Technical Note 3739 and NACA Research Memorandum L57D26 In addition, during NACA flight tests of these sounding rockets, instrumentation to be used during the IGY was tested and rocket-launching crews for the IGY were trained by NACA. The high-performance Cajun rocket motor of one of these sounding rockets was developed by NACA and made available for use in the IGY program. Five different agencies of the United States and their contractors are using the Nike-Deacon and the Nike-Cajun sounding rockets in the IGY program.

In support of the United States IGY program on artificial earth satellites, the NACA has invented, designed, and developed the compactly foldable and pneumatically erectable NACA 30-inch diameter subsatellite for use on the Vanguard launching system, and the NACA 12-foot-diameter satellite for use on the Explorer launched by the Jupiter-C launching system. The smaller subsatellite was proposed to the Technical Panel on the Earth Satellite Project of the United States National Committee for the International Geophysical Year on January 26, 1956, and the larger satellite on December 3, 1956 Both have been officially approved by the panel and are essentially ready for use. These are by far the largest earth satellites in the United States IGY satellite program. These two NACA-contributed satellites are the only known means whereby the density of the earth's atmosphere at the borders of space can be accurately measured, so that there may be known the altitude at which satellites of the future must orbit in order to remain in orbit the desired length of time

All of the foregoing research, including that in support of the United States International Geophysical Year program, has been performed entirely by the NACA with its own funds.

Mr. FULTON. Has not a scientist from behind the Iron Curtain had access to certain installations?

Dr. DRYDEN. No; they have not.

Mr. FULTON. Was it not on August 25 last year that they came to some installations in the United States on the missile program?

Dr. DRYDEN. They may have. They did not come to any installations of NACA.

Mr. FULTON. So that you can say firmly or categorically there has been no person of a foreign birth from behind the Iron Curtain that has had access to your facility, personnel, or consultations?

Dr. DRYDEN. What do you mean by "access to personnel"?

Mr. FULTON. I mean on your facility.

Dr. DRYDEN. No; there have been no visitors from behind the Iron Curtain to any NACA facility.

Mr. FULTON. My questions have been firm, but do you think they have been fair?

Dr. DRYDEN. Absolutely.

Mr. FULTON. And I hope completely nonpolitical.

Dr. DRYDEN. Yes.

The CHAIRMAN. Mr. O'Brien?

Mr. O'BRIEN. Mr. Chairman, I would like to continue briefly, if I may, on the urgency and continuing importance of what we are trying to do here, and what the President is recommending. I know that Congress feels it is important or you would not be here today before a new committee. I note from what the President has said that he regards this as a very urgent matter and a matter of continuing importance.

Nevertheless, it has been suggested in some places that because we and the Russians have shot some satellites up in the sky that we were overcome by a sort of science-fiction fever, and that when all this levels out and we get over the excitement, that this whole problem will not be as important as we now consider.

I would like to ask you this question: Do you believe in the long-range scheme of things that what we do in this field, whether the Director is of Cabinet rank or not, is just as important as, if not more important than, the legislation creating the Atomic Energy Commission?

Dr. DRYDEN. I think, looking at the future, this is quite true. The difference is that I do not think we can spell out so clearly the character of the military weapons systems as we could at the time AEC was set up, in the long run.

Mr. O'BRIEN. You think that this problem is of such importance that we are not going overboard, for example, in suggesting the possibility that this agency have Cabinet rank, or rank very close thereto?

Dr. DRYDEN. I think I answered that earlier. The question is merely: Shall you do it at the start or shall you wait and see whether this actually does grow to the size that you are thinking about?

Mr. O'BRIEN. Thank you very much.

The CHAIRMAN. You seem to be rather fixed on the organizational setup provided for in the bill, with a single director. Would you apply that to all other commissions?

Dr. DRYDEN. I think if you want clear-cut authority from some one person who is responsible, that is a pretty good model.

The CHAIRMAN. Do you give recognition to the fact that the individual might be mistaken?

Dr. DRYDEN. This, I think, is one of the chief virtues of this Advisory Board, who continually has it in view, compared to the difficulty of those who do not have some of the views of the Agency.

The CHAIRMAN. So you consider that the Advisory Board will check on the individual?

Dr. DRYDEN. In a way. As I expressed it before, this makes the Director and the Agency act in the goldfish bowl of complete knowl-

edge, have access to any information relating to the operations of the Agency from people who are not full time identified with it, who are acquainted with the broad aspects of this space business, and who know what people on the outside think.

I think this is one protection that such an advisory board gives to the Congress and to the administration.

The CHAIRMAN. In other words, you rely on the functions of the Advisory Board to fill in the gap where an individual might make mistakes.

Dr. DRYDEN. I would think it is very parallel to the board of directors of a company. If the board of directors does not like the way the company is operated, they will try to get a new president. I would presume this Board would do the same thing.

The CHAIRMAN. You proceed on the theory of the structure of the Board and the Congress serving the people.

Dr. DRYDEN. Essentially not in all complete details, but the idea of a group of people who are continually examining what is going on and who are in a position to bring this to the attention of someone outside the Agency.

The CHAIRMAN. Why would not a commission of 3 or 5 be more effective?

Dr. DRYDEN. If they are full time, they are full time employees of the Agency. They are on the receiving end of the inspection. You have to have somebody, then, a committee of Congress or someone who is continually monitoring.

The CHAIRMAN. I know, but every agency appoints an advisory board. There is nothing new about that. On this, one is provided for by statute. You have several hundred persons on different committees.

Dr. DRYDEN. There is a General Advisory Committee to the AEC provided by the statute.

The CHAIRMAN. Will you repeat that?

Dr. DRYDEN. The General Advisory Committee to the Atomic Energy Commission is provided by statute. The National Science Foundation Board is provided by statute. I think there are a considerable number.

The CHAIRMAN. The AEC, of course, has a Commission of five men.

Dr. DRYDEN. Yes; but they have a General Advisory Committee also, by law.

The CHAIRMAN. But they have a Commission by law.

Dr. DRYDEN. Yes.

The CHAIRMAN. How much consultation did you have with Mr. Finan or your counsel or anybody representing you in connection with the drafting of this bill?

Dr. DRYDEN. I personally had discussions with him about 3 or 4 times. Paul, you sat in continuously, I think.

Mr. DEMBLING. Primarily the consultations I had with Mr. Finan and his staff were in terms of the functions of the Agency and the authorities that would be needed by the Agency to carry out the functions of that Agency as provided in the legislation.

The CHAIRMAN. Now you say the Board is advisory, but the language of the bill gives some powers beyond advisory; does it not?

Dr. DRYDEN. I do not read it that way.

The CHAIRMAN. Well, shall be consulted by you for basic propositions.

Dr. DRYDEN. This says you must discuss the budget with them, but it does not say that you have to follow their advice. That is why I call it advisory.

The CHAIRMAN. That is true, but when you appoint an advisory committee in accordance with general provisions of law, where you have the authority to do that, do you recognize that there might be a difference in the advisory committee than where it is definitely established by law?

Dr. DRYDEN. I do not understand the question.

The CHAIRMAN. Here is a Board specifically provided for by law and—

shall be consulted by the Director prior to (1) the initiation or substantial modification of policies or programs of the Agency.

Dr. DRYDEN. That is right.

The CHAIRMAN. If you are a member of the Advisory Board appointed by the President, would you not think that your views would be pretty well followed by the Director?

Dr. DRYDEN. If the Board is unanimous, I think the Director would want to be sure of his ground in doing differently, but I think in this case the matter would go to the President.

The CHAIRMAN. We are all conversant with human nature, you know. I am reading in here the human mind, human nature.

If I am a member of a board appointed by specific provisions of the law, and appointed by the President, I would consider that my power would be rather broader than if I were put in as a member of the advisory group by the head of an agency or by a commission.

Dr. DRYDEN. I would agree with that.

The CHAIRMAN. So that you can read into this that this Board will have more authority in its own mind than would be the case if it were not provided specifically for by law and appointed in accordance with the administration.

Dr. DRYDEN. They will be an influential Board.

The CHAIRMAN. Now, in the case of a weak director, it could be very harmful.

Dr. DRYDEN. This, I think, assumes that the President will appoint a weak director and a strong Board.

The CHAIRMAN. No. I am not assuming that at all. Those things do happen, of course.

Dr. DRYDEN. Well, if the director is weak he should be removed.

The CHAIRMAN. That is easily said, but sometimes hard to do. Of course, we are not wedded to this language. You would not mind if the language says the Board may be consulted by the Director, would you?

Dr. DRYDEN. I personally would have no objection.

The CHAIRMAN. And you would not object to changing the language giving complete respect to the orders of the President in connection with any transfer which takes place under section 8?

Dr. DRYDEN. Not at all; I would have no objection.

The CHAIRMAN. Those are details.

Dr. DRYDEN. Yes.

The CHAIRMAN. You would have no objection to provisions being put into the bill providing for, say, a liaison between any new agency and the Defense Department?

Dr. DRYDEN. I personally have none.

The CHAIRMAN. And with the AEC? Those are the two real agencies where matters of great importance probably would develop.

Dr. DRYDEN. I think it would be more economical to do it on one liaison group than on the large numbers.

The CHAIRMAN. Liaison for both?

Dr. DRYDEN. Yes.

The CHAIRMAN. That is a matter for consideration. But some operating group meeting frequently or constantly——

Dr. DRYDEN. You see, I come back again. In my own opinion the Board as there proposed, with membership from AEC, from Defense, National Science Foundation, and other agencies concerned, is an effective way of accomplishing what you are proposing to do, or at least discussing, separate liaison committees for each agency.

If you have one with AEC and one with Defense and another one with Science Foundtion on their problems, there are many Government agencies in which there should be liaison. My understanding is that is what the draft of the bill proposes to do by having eight Government representatives on the Advisory Board.

The CHAIRMAN. Assuming the enactment of a law establishing—well, you would not feel offended if you were called an administrator, would you?

Dr. DRYDEN. No. That is all I do.

The CHAIRMAN. I know, but there is a difference in interpretation between being called a director and administrator in Government circles. Being called an administrator would indicate a high level of thought on the part of the Congress, and responsibility, and so forth.

You would have no objection to a joint legislative committee somewhat like the AEC performing similar functions?

Dr. DRYDEN. I assume that Congress will write into this bill whatever the congressional organization is that is decided on for space. I should think you would do that.

The CHAIRMAN. Now, it has been indicated to me, without mentioning the source of the indication, that there were some who feel that with the enactment of this bill, this agency would be only a matter of passing attention.

If we enact it into law and you are appointed director of this agency, or administrator, or whatever the committee might in its wisdom make the title, do you consider that this new agency, projecting your mind into the future—that means the immediate and the foreseeable

future—that this agency is necessary in the national interest of our country?

Dr. DRYDEN. I think so.

The CHAIRMAN. As such, you as the bureau director or administrator would do everything to see that the importance of the agency is advanced at all levels from the President on down?

Dr. DRYDEN. Yes. I have no commitment that I will be the director. I wish to make it clear for the record.

The CHAIRMAN. I know that; I understand that and I appreciate your modesty. I am trying to get your thoughts for the record.

Are there any further questions? Mr. Feldman?

Mr. FELDMAN. Dr. Dryden, I believe in answer to a question put to you by Congressman Ford, you stated that the advisory board as presently constituted operated in the nature of a board of directors.

Dr. DRYDEN. That is correct.

Mr. FELDMAN. I can see where you can reach that conclusion because the director is responsible to the board for his actions.

Dr. DRYDEN. That is correct. I am sorry if I was not clear on this point. The present board corresponds much more exactly to the function of a board of directors of a company.

Mr. FELDMAN. Yes. That was the question put to you by Congressman Ford. I do not think it was a question; rather it came out of a response to a question he asked.

Now, the present proposal which is before this committee changes that and makes the board advisory in function only; is that right?

Dr. DRYDEN. That is right.

Mr. FELDMAN. And the President is over the board, and so on. In that respect, then, it differs from the traditional way in which a board of directors operates; is that right?

Dr. DRYDEN. It does not have the power of the board of directors. It will deal with the same matters, as I see it; the same kind of matters as a board of directors, but instead of controlling, it will be advisory.

Mr. FELDMAN. In a company, for example, that has a board of directors, the board of directors can fire the president.

Dr. DRYDEN. That is right.

Mr. FELDMAN. What they are interested in is the bottom line, the performance of the company.

Dr. DRYDEN. That is right.

Mr. FELDMAN. Now, in response to a question asked you by Congressman Sisk earlier today, you characterized the new setup, at least the board, as in the nature of group of kibitzers. I am quoting you now.

Dr. DRYDEN. I was trying to illustrate that they perform a function of observing, commenting on, criticizing, and recommending to others with respect to the operations of the agency.

If the director and board work together, the board becomes a strong support for the director.

Mr. FELDMAN. In response to a question by Congressman McCormack, you stated there was no need for a specific liaison committee, because in effect the members of the advisory board were, in fact, acting as liaison because they came from different branches of the

service or the different branches of the Government that were interested in various phases of this program.

I do not see how you can reconcile that liaison activity with one of being kibitzers, and the liaison should have a defined function in order to perform efficiently. Do you not agree on that?

Dr. DRYDEN. There are two kinds of liaison. One is that of broad policy, broad issues. The other is the everyday working liaison in which at present we have military people in our laboratories.

They deal directly with the working level on the cooperative projects. That is a technical liaison.

Mr. FELDMAN. That kind of liaison is one thing. No liaison of the kind contemplated, such as the one existing between the Atomic Energy Commission and the military, is interfered with by the other type of liaison that you are speaking of.

Dr. DRYDEN. That is right.

Mr. FELDMAN. That exists between the AEC and the various branches of the military in the lower levels; is that right?

Dr. DRYDEN. That is correct.

Mr. FELDMAN. This is in addition to that, so the functions are different and they do act accordingly.

Dr. DRYDEN. I think the functions you talk about must be performed. We operate a good bit in an informal manner with the military services, and the AEC now. We go see Admiral Strauss and make some arrangement to put some people down at Oak Ridge to be trained.

You substitute for this kind of informal dealing a formal liaison committee, I have no objection to it; I have already stated this. The function has to be performed. It is a matter of how the function is performed.

Mr. FELDMAN. There could also be the fact that you could have the formal committee, and also have the formal arrangement down at the local level so that one does not interfere with the other.

Dr. DRYDEN. I can only say I have no objection if the committee wishes to write this kind of formal liaison, but I do think there are a number of Government agencies involved in the liaison and I prefer not to see a half dozen such committees.

Mr. FELDMAN. I could go along on that except that I do not think there is any need in some instances. You would not want to have a whole series of liaisons unless it became important, but we do not have that in the case of the military. Where there is actually a good deal of overlapping or duplicating or working together involved, then it is essential to have such a committee and also in the case of the Atomic Energy Commission, where they, too, have important projects that you are concerned with. However, I can see where in connection with other agencies, such as the Weather Bureau, it might not be necessary.

Dr. DRYDEN. I do not know why it is not necessary in the Weather Bureau if you go into this extensive meteorological program. I am looking ahead, and it seems to me there will be 4 or 5 Government agencies in which liaison is required.

Mr. FELDMAN. But you will have that liaison in any event; is that right?

Dr. DRYDEN. By the kind of method that we talk about, they are less formal than a formal liaison committee.

Mr. FELDMAN. Now, at the present time the Chairman of the National Advisory Committee for Aeronautics is elected by the committee by ballot, to serve for 1 year. Now, section 4 (b) of the new proposal provides that—

The Chairman shall be designated from time to time by the President from among the non-Government members of the Board only.

Dr. DRYDEN. Yes. The reason for that is to avoid a conflict of interest. To have the Secretary of Defense as head of the new agency, for example, which would be possible if you extended this to the full membership, to have Defense representing both Defense and the new agency. To avoid this conflict of interest it is provided that the Chairman be taken from among members who do not some from Government agencies.

Mr. FELDMAN. Assuming that one of the members of a non-Government agency was the head of a large company that is contracting with one of the services or with NASA, would the conflict-of-interest provision apply there, or your reasoning in connection therewith?

Dr. DRYDEN. I think so. This is a matter which you will want to consider. At present there is no problem of industrial members on the Board because the present NACA does not award contracts to anybody.

The whole matter is on a completely technical research level. The new agency will be involved in such things and I would think that you would want to consider this problem. I assume the President would also want to consider it in appointing the members of this Board as to whether it would not be a real conflict of interest if the principal officer of some large contractor having contracts with the Government were made Chairman.

Mr. FELDMAN. If the Board as presently constituted were appointed by the President, might that not be a serious question?

Dr. DRYDEN. It depends on who he appoints as Chairman.

Mr. FELDMAN. I am talking not only of the Chairman but the membership of the Board itself.

Dr. DRYDEN. I would have to look into the details of the relationships of the people now on the Board.

Mr. FELDMAN. I think it does present a serious question.

The CHAIRMAN. Would you submit your recommendations for language to be incorporated in the bill that will meet the situation?

Dr. DRYDEN. Yes; we will.

(Letter in compliance with request follows:)

NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS,
Washington, D. C., May 23, 1958.

Hon. JOHN W. MCCORMACK,
Chairman, Select Committee on Astronautics and Space Exploration, House of Representatives, Washington, D. C.

DEAR MR. MCCORMACK: During the hearings before your committee, you requested language that might be incorporated in the bill (H. R. 11881) regarding conflict-of-interest provisions (see p. 1017 of the transcript).

It appears that there are sufficient statutory provisions at present which would govern the activities of Board members. The conflict-of-interest sections

of the United States Code to which I refer are 18 U. S. C sections 281, 282, 283, 284, 434, and 1914, and 5 U. S. C. section 99.

In this connection, I call your attention to "A Staff Report to Subcommittee No. 5 of the Committee on the Judiciary, House of Representatives," dated March 1, 1958, entitled "Federal Conflict of Interest Legislation."

Sincerely,

PAUL G. DEMBLING, *General Counsel.*

Mr. FELDMAN. Section 4 (b) of the proposal before this committee provides that, "The chairman shall be designated from time to time by the President," and so forth, among the nongovernmental members of the Board. I think you answered that question, but one more point in connection with it is this:

It would seem to me that there is a possibility for embarrassment in a situation of that kind, that I would think that the President might have some difficulty in getting members who are not connected with any of the services and who might be of real value to the committee.

Dr. DRYDEN. This is the perennial problem of getting expert help in Government for such positions as Secretary of Defense or any high position.

How do you find anybody that knows anything about the subject that is not involved in some relations with the Government?

Mr. FELDMAN. That is why we require a divorcement from their past connections.

Dr. DRYDEN. Yes.

Mr. FELDMAN. So you would say that this matter requires consideration?

Dr. DRYDEN. I would agree.

Mr. FELDMAN. Now, in answer to a question put to you by Congressman Natcher, you said you never permitted the Board to hold up action.

Dr. DRYDEN. That is right. They have delegated their powers to me, for example, to begin on military research and report afterwards what has been done, and they delegate powers to make contracts with universities on research.

The present situation is that the Board has delegated powers so that there is no holdup of action.

Mr. FELDMAN. I believe you indicated that you never had to go to them for the purpose of signing a contract.

Dr. DRYDEN. That is right.

Mr. FELDMAN. But did you ever have to go to them in connection with even negotiating or entering into a contract?

Dr. DRYDEN. They cannot enter into that picture at all.

The CHAIRMAN. Doctor, I think this is a good time to suspend because there is a rollcall going on.

We will come back just as soon as possible.

(A short recess was taken.)

The CHAIRMAN. The committee will be in order.

Mr. Feldman, will you continue your questioning.

Mr. FELDMAN. Doctor, I just wanted to summarize the previous testimony. I wonder whether you will agree with me that the proposals did not consider the possibility of the conflict of laws in the changeover from the present functions of the NACA to the new

functions which would enable it to enter into contracts and actually produce space vehicles?

Dr. DRYDEN. I do not recall any discussion of this subject. I might ask Mr. Dembling if he does.

Mr. DEMBLING. There were some discussions about the conflict of laws as you have phrased it. It was felt that if the legislation as drafted were passed, this would obviate any problem between the two sets of laws that might be on the books.

In other words, this piece of legislation would repeal any inconsistent pieces of legislation.

Mr. FELDMAN. Can you point out the provision in this new proposal which would cure the conflict-of-interest setup?

Mr. DEMBLING. Conflict of interest or conflict of laws?

Mr. FELDMAN. Conflict of interest.

Mr. DEMBLING. No, sir; this is something I believe Dr. Dryden mentioned before that should be given some attention.

Mr. FELDMAN. Now, Dr. Dryden, in the Atomic Energy Act there is a specific provision which requires that the Commission receive authorizations from Congress to build facilities. There is not a corresponding provision in the new proposal.

Would you favor such a provision?

Dr. DRYDEN. This is based, I believe, on the present situation where there is no requirement in law that there be authorization. Of course, this means that the facilities are subject to points of order, at least on the House side.

We have for the past several years submitted authorization legislation for all construction. I think only in one case has it ever gone all the way through the Congress.

We have appeared before the Armed Services Committee, which is the present legislative committee. They have gone over our construction program and in many cases the bill has passed the House, the appropriation bill usually has beat the legislative bill through.

That being true, the members have not wanted to take the time to process the authorizing legislation through separately.

The only thing we would plead for is what we have under our present agreement, the simultaneous consideration of authorization and appropriations.

In other words, if you have to come for authorization one year and appropriation the following year, this runs into long delays in the securing of special facilities which may require 3 years to build.

So that if you write this in we would propose that you at least make room for the idea that both the authorization and the appropriation could be considered at the same session of Congress.

Mr. FELDMAN. Dr. Dryden, there is no provision in the new proposal concerning patents. Would you object to such a provision which would protect the Government in that field?

Dr. DRYDEN. I do not know how to answer this question in general. In principle I certainly would say that there is no objection.

I think, myself, that the patents should be handled very broadly with respect to all Government agencies. That if you get different policies in different acts you get into a lot of confusion.

At present we have taken the view and our regulations provide

that the Government reserves rights in anything developed with its money.

Mr. FELDMAN. You would have no objection to incorporating a corresponding provision into this bill?

Dr. DRYDEN. So long as we don't have different policies than other agencies with which we have to deal. That would make for a lot of confusion, sir.

For example, if we had one group in the Navy working for the agency, the Navy had different patent legislation than the new agency, you could see the bind you would be in.

Mr. FELDMAN. You would feel that the public interest requires the inclusion of such a provision?

Dr. DRYDEN. Right.

Mr. FELDMAN. In your opening statement you pointed to the fact that in 1952 a gentleman from Bell Aircraft proposed the setting up of a space committee.

Dr. DRYDEN. Not quite. I said he thought that the agency ought to begin studying what were the problems associated with space flight, what kind of facilities were needed, what kind of research is needed, in order to prepare for such operations.

Such a study was started in the laboratories. At a later date we came up with a proposal, as a result of these studies, for a special research airplane.

I would like to say that the proposal for the research airplane was in 1952 and it took all those years to get going.

The proposal for a research airplane came some years later, after the paperwork in the laboratory study had been finished.

Mr. FELDMAN. You also stated in the prepared statement that the committee regarding the study of space or regarding space problems, was not appointed until last fall.

Dr. DRYDEN. That is correct.

Mr. FELDMAN. The bill in section 2 (6) lists under declaration of policy:

Cooperation with other nations

Section 6 (4) speaks of the scientific community.

How broadly do you interpret the words "scientific community"?

Dr. DRYDEN. That, I think, was intended to be the United States scientific community.

Mr. FELDMAN. Do you include scientists abroad in the application of section 2 (6)?

Mr. DRYDEN. I would say they would be included if the policy of the Government and so on did provide in fact for their national scientific cooperation.

As the words are written, it does not restrict it to the United States, although I think the intent of writing at the time was thinking of the United States.

Mr. FELDMAN. Do you have any views regarding the inclusion of scientists from abroad?

Dr. DRYDEN. I think this is a desirable thing to do at some stage. There is the problem I mentioned before that space flight at pressent depends very heavily on military developments and that there is a security problem involved at the present moment.

Mr. FELDMAN. Are you acquainted with a proposal that was made not too long ago concerning the plan for an atomic airplane?

Dr. DRYDEN. I am familiar with it, yes.

Mr. FELDMAN. This project was under consideration for some time by the military and by the Atomic Energy people; is that not so?

Dr. DRYDEN. That is correct.

Mr. FELDMAN. And they were ready to go when a committee was appointed to look into the matter; is that right?

Dr. DRYDEN. I think there had not been approval within the Department of Defense at the time this committee was set up.

Mr. FELDMAN. Are you sure of that?

Dr. DRYDEN. I am sure of that.

By the way, I am appearing on this subject before Mr. Price's committee on Friday. I am not sure that I can go very far on it in open session.

Mr. FELDMAN. I will not pursue it any further. Are you a member of that three-man committee?

Dr. DRYDEN. Four-man. All of them all appear before Mr. Price, but I believe in closed session.

Mr. FELDMAN. I would just like to ask this question—I don't believe this will violate any security provision: How long did the committee study the proposal?

Dr. DRYDEN. The committee itself, as this particular committee, was active a relatively short time. I don't remember, but it was 2 or 3 weeks. Each member of this committee had been associated in the past with innumerable committees connected with the atomic energy propulsion aircraft program so all of us had been exposed to briefings on this subject and had visited contractors many times.

So I think it is not fair to take the time that the committee was actually functioning as the time that the people took to get acquainted with the program.

Mr. FELDMAN. Dr. Dryden, if this does not violate security in any way, I would like the answer to this question:

I understand there has been a project of shooting into orbit an inflatable satellite for air density measurements.

Dr. DRYDEN. That is the thing which you have seen here today.

Mr. FELDMAN. This, I understand, is purely an American concept.

Dr. DRYDEN. Yes. Mr. O'Sullivan, who is in the room, is the man who thought of the scheme.

Mr. FELDMAN. Would you care to tell us about it.

Dr. DRYDEN. I think I have explained it pretty completely in the testimony before.

Mr. FELDMAN. This was partof the IGY program; is that right?

Dr. DRYDEN. The order of events was that Mr. O'Sullivan came up with this idea, the possibility of doing this. It was submitted to the IGY committee by the NACA and was accepted as a part of the satellite program.

Mr. FELDMAN. When new proposals come to the NACA, would they come directly to you?

Dr. DRYDEN. Yes.

Mr. FELDMAN. Would you then submit it to the appropriate committee or subcommittee?

Dr. DRYDEN. Normally I call in members of the technical staff who are acquainted with the various specific fields.

Mr. Feldman, the way scientists use the word, or the way scientific administrators work, no one can have all the knowledge to assess a

technical program, so they get expert advice from the staff. Normally these projects are not submitted to our advisory committees for approval. They may be submitted for information, for comment.

Mr. FELDMAN. I understand that space biology is of great importance to the development of the program.

What facilities does NACA operate of this nature such as centrifuges, low-pressure changes, and so forth?

Mr. DRYDEN. The NACA operates none. It is not proposed that the NASA duplicate facilities in this field.

In the X–15 program, for example, the centrifuge at Johnsville, Pa., which is owned by the Navy, has been used for various experiments.

The idea here would be that the new agency would strengthen where necessary the work that is now going on.

Mr. FELDMAN. We further understand that upper atmosphere sounding research is a key part of the program. What rocket sounding work is the NACA carrying on?

Dr. DRYDEN. We ourselves are not directly doing rocket soundings. Our people did develop one of the rockets which is being widely used in the IGY program.

NASA will certainly have to see that there is adequate rocket sounding program. There is a good bit of information which can be obtained much more cheaply by rocket soundings in the upper atmosphere and this work must be provided for either by stimulating other people, supporting other people; it would be the responsibility of the new agency to see that this is done.

Mr. FELDMAN. I have no further questions.

The CHAIRMAN. Mr. Sisk, do you have a question to ask?

Mr. SISK. Dr. Dryden, just how urgent do you feel that this legislation is which we have before us?

Dr. DRYDEN. I think it ought to be passed at this session of Congress. Otherwise, there will be a great deal of confusion and backing and filling.

Mr. SISK. My reason for asking that question, and I may be entirely wrong and I hope you do not take this as a personal criticism, but it seems to me as I have listened all day to the testimony here that what in a way you propose is a bit of upgrading of the present committee or board and a little updating of the program rather than any specific change, and that we will wind up doing business at the same old stand.

As I say, maybe I wholly misinterpret your whole position, but you do feel that there is a need of expediting a program of this type?

Dr. DRYDEN. Entirely so. I am sorry I did not make it clear that this is a new agency, not NACA being given another job.

As we visualize the organization at the present time, there will be a completely separate line, if you like, devoted to space-flight operations which will be separate from the pure research activities that go on in the present laboratories, that a great deal of work will be done by contract with other agencies.

I do not consider it either an assignment of this space to NACA or operating of NACA, but utilizing the nucleus of the people who are experienced in some of the technical fields needed in space; namely, aerodynamics, propulsion, and structures, supplementing those people and facilities at a value of several hundred million dollars, with a

mechanism for utilizing other groups in the country in the space flight program.

Mr. SISK. You stated earlier today, and I agree with you, that the NACA had done a good job for 40 years and has a good record.

Yet you agree that there is need today, because of recent events, for a better type of program or for more expeditious action.

Dr. DRYDEN. A different type of program, a civil hardware development and space operations program in addition to the research work which the NACA has done and will continue to do.

Mr. SISK. Many of the witnesses who have been before this committee, of course, lean more toward the idea of a commission type, a 3- or 5-man commission with a specific job and full-time duty.

Of course, your recommendations are contrary to that and maybe you are right.

I do not propose to disagree at this moment, but I have felt that maybe you did not feel the urgency. I was curious to know whether you felt that the NACA as it is presently constituted can go ahead and do the job we want done.

Dr. DRYDEN. When you say as presently constituted, no; this is a new agency. There will be new people; there will be new organizations associated with it.

Mr. SISK. That is all, Mr. Chairman.

The CHAIRMAN. Are there any further questions of Dr. Dryden?

Mr. KEATING. On that point, is it not a fact, Dr. Dryden, under the terms of this very measure the NACA goes out of existence and its duties are absorbed into the NASA?

Dr. DRYDEN. That is correct.

The CHAIRMAN. Thank you very much, Doctor. We appreciate your appearing before us.

For myself and the members of the committee, I express to you our thanks.

Dr. DRYDEN. I thank you very much for the very friendly hearing that you have given me even when we have differed on some things.

The CHAIRMAN. Well, you are going to make some suggestions along the line we requested?

Dr. DRYDEN. Yes, sir.

The CHAIRMAN. The next witness is Dr. Simon Ramo, vice president of the Ramo-Wooldridge Corp., of Los Angeles, Calif., and president of the Space Technology Laboratory which is connected with the corporation.

The Chair is going to yield to Mr. McDonough.

Mr. MCDONOUGH. Thank you, Mr. Chairman. I appreciate the courtesy.

For the benefit of the committee, I would like to say that this is the first witness we have had from industry on this very complicated subject, and I think a very capable and competent witness because of the broad experience he has had in the practical application of these new scientific developments in space vehicles, missiles, rockets, and other things.

With Dr. Ramo is Mr. A. F. Donovan, Director of Aeronautical Research in the Space Laboratory of Ramo Wooldridge, who, I understand, will also testify.

So I am happy to welcome you to the committee, Dr. Ramo.

STATEMENT OF DR. SIMON RAMO,[13] EXECUTIVE VICE PRESIDENT, RAMO-WOOLDRIDGE CORP., LOS ANGELES, CALIF.

Dr. RAMO. Some of the important issues underlying both a national space-research program, as distinct from military space programs, and the formation of a civilian research agency to carry out such a research program independent of the Department of Defense can be stated as a series of specific questions. These are listed below, together with the writer's opinion as to the answers.

In addition, there are attached hereto three other documents, as follows:

Appendix A. A recent, unpublished paper, "Man in Space—An Evaluation and a Justification,"

Appendix B. A copy of a speech presented to the Air Force Association at its Annual Jet Age Conference on February 28, 1958, "The Potentialities of Space Weapons Systems."

Appendix C. A reprint of a paper published in the Astronautics Journal of the American Rocket Society, August 1957, "ICBM—Giant Step Into Space."

These three attachments provide elaborations on some points believed to be pertinent to the problem, showing the relationship of space-research projects to military projects, and generally commenting on the importance of space projects for both military and nonmilitary application.

Question. Are there important space-research areas exclusive of military space-weapons systems?

Answer. Much valuable investigation of other planets, the moon, and the characteristics of the space between these bodies appears today to involve only exploration and pure research into the laws of nature, with no clear military application. For example, answering the question as to whether there is life on Mars does not have any obvious military consequence.

Space research defined in this way may well provide information on the basis of which military weapons systems of a radical and important kind will later be invented. But this kind of generalization can be used for all forms of pure research. All new discoveries in science can be expected to open up new applications, both military and nonmilitary.

Question. Does space research require or deserve a separate agency?

Answer. Research in medicine, biology, nuclear physics, and other physical and life sciences all promise benefits and can all be classed

as vital in the long run to our security or our happiness. If all such basic research is controlled by the Department of Defense, it is justifiable to fear that we may not explore sufficiently the longer range aspects of science. In this sense, it is reasonable to consider a separate civilian agency to direct and sponsor nonmilitary space research. But this will work to the detriment of the Nation if, in the process of trying to separate away pure research in space from research and development necessary to insure military space capability, proper consideration is not given to the extremely important connection between these two aspects of space. No matter what basic space research the new agency may carry on, no arbitrary rule should prevent the Department of Defense from engaging in that space research it may deem essential to sound advanced military developments. In other words, the new space agency should not be thought of as having a monopoly on space research.

Moreover, study of a separate agency for space research can hardly be considered thorough, unless it is recognized that space research must compete for the Nation's limited physical and technical resources with other important long-range research as well as with urgent military applications of space. We have to be sure that there exist efficient means for investigating whether space research is going to provide the Nation with more potential scientific information of benefit to us and mankind in general than other competing fields. Is it better to cure cancer, or to find out if there is life on Mars? Who will answer such questions? It is obvious that the professional scientist alone should not be handed the decision authority over whether it is better to land a man on Mars or to spend the same resources on attempts to control the weather on earth. The scientific experts can help by indicating how much can be accomplished in a given time at a given cost, but ultimately the people as a whole, through their elected representatives and their Government officials, must make these choices, because they depend upon factors of broad national scope.

But this suggests that if we are to have a separate agency to direct Government-sponsored basic research outside the scope of the Department of Defense, then that agency should cover not just space, but other aspects of the Government's research program as well, including the nuclear, medical, biological, and other fields. Otherwise, it appears to be equally deserving to have a special agency for each and every important field, and with this, of course, the cumbersome and unsolved problem of refereeing objectively the distribution of resources amongst these.

Question. Granted a separate space research agency, how closely must it work with the Department of Defense?

Answer. There must be exceedingly close ties between the programs of the space agency and the Department of Defense in order to utilize to the fullest the funds assigned to the space agency. This comes about primarily because space research is very expensive, particularly as to the required apparatus, the facilities for testing and fabrication, and the development of countless auxiliary techniques for measurement and handling of apparatus and data. Unless the new space agency relies heavily on the big boosters, the detailed hardware, and the launching facilities that the Department of Defense has to provide anyway for its urgent large-scale military programs, the budget

of the space agency will have to be many times greater to approach the same potentialities in getting results. Indeed, to the first approximation, basic research in space, beyond foreseeable military applications, can be described as a small addition to the large military space program. If the agency obtains funds beyond such a small addition, it probably will be a disproportionate expenditure of funds in space research as compared with other forms of research also important to the Nation and deserving of Government support.

I would like to elaborate on this in view of some of the discussion I heard this morning.

In particular there was mention of two examples of peacetime, nonmilitary space research or space applications. One was in the field of communications, to improve worldwide communications, and the other was weather prediction and control.

Now, I submit to you gentlemen that that part of our Nation, that group that has the greatest need for improved communications and as a result is already involved in the initial steps of planning improved communcation systems using satellites, an indicated approach, is the Department of Defense.

We have facing us a new concept of "one world simultaneity," of military operations, in which some launching activities on one part of the earth's surface can mean, only minutes later, the destruction of a vast part of the rest of the globe. It is obvious that the military has an urgent need for a class of communication system superior to what exists today in which in effect the whole world is tied together in a vast integrated network that allows military command to be in communication with any part of its operations.

Communication's theory today suggests that satellites are going to be an important ingredient of such new communications systems.

As the larger boosters become reliable, the only step yet to be taken, these larger communications systems will become possible and it is my opinion that the Department of Defense, if it does its job properly, will have to seek funds for an urgent large communication system.

Now, if we talk about weather prediction and control we have something similar. We can talk about various groups, the farmers, the military, even those engaged in the entertainment business, the airlines certainly, that have a need for improved weather prediction.

But of all these groups, the one that stands at the top of the list, based on national urgency, is the military.

I can even cite such details as that the first operational ICBM's have an error contribution to their "miss distance" that comes about because we are not in a position to predict accurately the surface wind over the target.

And, in fact, if such prediction could be made more precisely the effect is to increase the effectiveness, the equivalent weight, of the bomb that is carried.

Now, this is by way of only one of many examples that the Department of Defense has the No. 1 need for improved weather observations, prediction and, eventually, control.

One final example is the large rockets which were mentioned a number of times. If we desire a million-pound thrust for various purposes, it should be recognized that acquiring that million-pound thrust means merely an extension of the large engines that are already flying and in production on Department of Defense programs.

I cannot give, in an open session, the thrusts that are available today, but it means something like a 2-to-1 increase in dimensions to get to the million pounds—no basic change to entirely new processes for combustion or entirely new fuels.

So that the quickest way to get a million-pound thrust is by an extension, you see, of a large military program.

By these remarks I do not seek to give the impression that there should not be a separate civilian space agency.

Rather, what I am trying to express is the belief that, if we properly assess the importance of space to defense and if we plan that the Defense Department shall be a strong department that primarily is responsible for defense, then the new space agency is one of the groups and not the only group in the Nation that provides space research. There must be a great deal of close coordination.

Just such coordination, incidentally, has existed between NACA and DOD on aerodynamics.

The Department of Defense has developed its airplanes, making use to a considerable extent of information that comes from NACA, but no effort has been made in the past to give NACA a monopoly on aerodynamics.

Question. Can NACA serve as the basis for the new space agency, or is an entirely new organization needed?

Answer. In my opinion, NACA is an ideal starting organization for the new agency. It enjoys an outstanding reputation for results and has a good staff. It also has very considerable background and strong beginnings in space research.

However, it will be necessary, in order to properly exploit the national resources available for space research and to minimize the required expenditures, to augment NACA with planned supporting and parallel research contracted for with university, industry, and other private groups outside of the Government. Of course, these additional research tasks should be administered by the same group that administers the "in-house" work by the basic (NASA) Government organization.

Question. Considering only nonmilitary space projects, do you believe that any project in which the Nation is interested and which involves any vehicle in outer space should permanently be managed by the separate space agency?

Answer. In time, a typical so-called space project will involve a wide range of equipment and engineering developments quite apart from the individual piece of equipment that may be in outer space. For example, a weather prediction and control system may encompass billions of dollars worth of equipment and employ tens of thousands of people spread geographically over the entire Nation and maybe a good many parts of the world. This system will consist of a number of vehicles in outer space costing some millions, or at most tens of millions of dollars. The system will include also observations of all kinds made from airplanes and balloons, and from ground stations all over the world, including airborne and ground radars. It will include also thousands of communication links going into central points where data are stored and where data are computed in massive electronic computers, where automatic selectors of past data feed into data processors together with new incoming information to form conclusions,

with the results communicated to various parts of the world where all kinds of actions are taken. I would imagine, in other words, that a weather prediction and control system a decade or two from now will consist of a multibillion dollar installation with the space vehicles' parts a relatively minor part of the whole. It would be illogical then to think of such a system being permanently contained and controlled by the space research agency, which should instead limit itself to research.

An analogy to the automobile industry may be helpful here. Let us imagine that we are back in the days when someone has succeeded in building the simplest possible prototype of an internal combustion engine, and has succeeded also in tying that to the wheels of a simple wagon of some kind, and we are thus aware that the horseless carriage era has arrived. We are in a race with Russia to see who can propel such a vehicle down the road for the greatest distance and the greatest speed, one having succeeded in doing it for 500 yards, the other for a mile, with speeds of a few miles an hour. How difficult it would have been at that time for us to have imagined a multibillion dollar industry involving gasoline stations by the hundreds of thousands throughout the world, with millions of people employed in such auxiliary tasks as handling of spare parts, making and selling tires, writing of advertisements for the automobile industry, special kinds of steels and chromium, developments in plastics and glass, and numerous auxiliaries such as shock absorbers, speedometers, etc. If we had at that time created a special research agency in the Government to control internal combustion engine research, would we expect that agency to go on in perpetuity to direct and control the activities of the gigantic automobile industry? It is in this sense that I suggest we look ahead to such items as have been described above as weather prediction control, and realize that what we now regard as experiments in space will eventually prove to involve large new industries, many additional engineering fields, with the space components, now so conspicuous, being virtually lost in the myriad of equipment and man-machine problems that will develop.

Question. How can we best go about creating the content of the space-research program?

Answer. There are literally hundreds of important experiments worth doing in space beyond those that have immediate military potential. Data collection in space is valuable to many fields of science. All scientific groups, such as the geophysical, astrophysical, and biomedical, can be expected to originate enough requests for data collection that each group alone could use up the entire budget assignment. The directors of the new agency and their scientific advisers must first list these desired experiments, these requests for information on space. Then they must compare this with another list, a schedule of activities and availability of apparatus, facilities, and techniques from the large military space and ballistic-missile programs. The first important exercise, I believe, is one of matching these to the greatest extent possible, scheduling the easy things first whenever they are logical steps and whenever they can be added at low cost to the military program. Expensive dead-end experiments should be severely scrutinized, and large-scale development of major boosters, major testing ranges, and the like, when they appear to have narrow and short-lived application, should be avoided.

In the end, the specific experiments, whether to orbit Mars, make measurements near the Sun, put biological samples into space, or concentrate more heavily instead on cosmic-ray measurements in space—these must all be decided by compromises amongst experts who know the availability of hardware, the schedule possibilities, and the relationship to military programs, and who combine appreciation of the several fields of science. It is unrealistic to tie a decision concerning a separated space agency to any specific program suggestion, however broad. Whether the agency is or is not a good idea clearly depends not on resolving debate as to whether we can or cannot put a man on the moon in 4, 6, or 10 years, but rather on some of the broader issues enumerated above.

Mr. Chairman, that concludes my statement.

The CHAIRMAN. I notice you have also, accompanying your prepared statement, an evaluation and a justification of man in space prepared by you.

Dr. RAMO. Yes, sir.

Also, you have appendixes B ond C, and they will also be made a part of the record.

(The material referred to follows:)

APPENDIX A

MAN IN SPACE—AN EVALUATION AND A JUSTIFICATION

By Simon Ramo, president, Space Technology Laboratories, division of the Ramo-Wooldridge Corp., Los Angeles, Calif.

No one now doubts that at some future date man will land on the moon and return. He will visit the other nearby planets. We may even be expected in future years to start colonies on these other space bodies.

We are sure these things will happen, because we essentially know how to make them happen today, and a good deal of what is needed in the techniques and in the actual apparatus will be available automatically from urgent military programs, such as the intercontinental ballistic missile development.

But despite the important start that military developments will provide to us in making it easier for man to enter space, it will still cost a substantial fraction of the Nation's technical and physical resources to conduct "man in space" experiments and to attain the end result of true capability and accomplishment in putting man into space and on these distant bodies, and to bring him back safely.

While we have become aware of our approaching capabilities for conducting such experiments, we are also beginning to realize that, in both the fields of urgent military development and pure conquest of the unknown, there are many more valuable tasks that we cannot possibly do all at once. Whether we like it or not, we and every other nation on the globe have distinctly limited resources compared with the possibilities we are capable of imagining. It has become true that imagination and idea promotion are the easy-to-get commodities. We must now clearly combine wisdom with imagination. Our future security as a Nation, and our ability to contain the world in a reasonably stable and happy state while making transition to the new, more technical society toward which we are headed, will both hinge on how well we make our decisions. We must be superior to other nations in what we choose to do out of all that we can do. The world may be inherited not by the nation that first escapes from the earth on the grandest scale, but rather by that nation that does it just often enough and does a lot of other things besides.

Let us take, for example, this question of putting man in outer space, in an orbit, out to the Moon and back, or out to Mars or Venus. How shall we class this effort? Urgent, or relatively low priority? As a scientific experiment will it yield us, do we think, more than the same resources committed to other explorations of the many unknowns that remain in nature? As a military poten-

tial, does it offer the possibilities of weapons systems superior to those in which man is restrained to the earth and a limited air-filled region above it?

It can be assumed that man's curiosity about the many unknowns of outer space will not be permanently satisfied by the mere placing of meters out in space. Man will have to go there to see for himself. We can investigate by instruments alone a very large fraction of what there is to know about the other planets and about the conditions in space between planets. But if we ask finally for sufficiently detailed examination of conditions and matter on the other planets, the instrumentation required becomes so complex, heavy, and difficult that man at some point becomes the cheapest, lightest, and most practical in strument for making such examination. Ultimately, in other words, man's appearance on the moon and the other planets is inevitable, even though what we shall learn and how useful that new knowledge will be is difficult, if not impossible, to predict.

But is it urgent to put man in space? Does national survival hang on it? If so, then 1 of 2 things must be true. We must see some direct military weapons systems requiring man in space. Failing this, we must identify some missing scientific knowledge, the gaining of which requires visitations by man himself to the moon and the other planets or to the space between them, which scientific information will then make possible the design of improved weapons systems that will control the earth. If we see neither a direct military requirement for a man in space nor any scientific data that man must go out and collect on which a necessary military strategy depends, then it would appear that putting man in space must be classed under the heading of long-range speculative research and exploration. In terms of national emergency, this could then be far from the highest priority project.

Now, there are those who believe and say that it is urgent indeed to put man on the moon or, generally, in outer space "To control the moon is to control the earth," these enthusiasists will tell us. When we ask why, the answers tend to be too general to criticize. Of course, unsound justifications are very common to. We often hear the mistaken impression that a bomb dropped from a satellite will fall to the earth. Of course it won't. It will reach the earth only if it is pushed away from the satellite with the right amount of force and with controlled direction, the whole launching operation being more difficult than that of launching an ICBM from a point on earth. Also, the flight would take very much longer. More important, the cost of putting up a satellite with its associated equipment capable of doing useful strategic bombing would permit the building of a very large number of land-based or submarine-based long-range ballistic missiles to drop the same H-bomb. In terms of insuring that we have an invulnerable retaliatory capability at a cost we can afford, putting our H-bombs out in space or on the moon, with the necessary means for assuring that they will come down when desired to the right places, looks like a different but poorer way of doing it. Outer space is new, but so is the bottom of the ocean; this does not mean we should put our retaliatory force there.

Even if we went to the greatly more complicated and costly, and apparently poorer way of retaliating by putting our H-bombs in orbit out in space or on the moon, it is not at all clear today why a man would be helpful. So we have two hurdles to clear in trying to see the logic behind such proposals. Space weapons do not look today as good for bombing as does the ICBM, which is a space weapon in actuality, but one that is under our control at home until we are ready to use it. The ICBM uses space to the extent that it pays off. It buys us the most important advance over nonspace vehicles, a great reduction in time between the initiation of the attack and its effect. The second hurdle is that everything that we might plan to have the man do, if he were out in space participating in the H-bomb raid, we can also arrange to do by remote control with the man remaining on earth.

But the enthusiasts go on to say it has always been true that the "high ground" gives the adversary an advantage. The moon is up there higher than any point reached by an intercontinental ballistic missile, and of course by any manned airplane. The moon looks down on the earth, therefore it controls.

We are too sophisticated today in both science and military strategy to accept such a generalization. Once we have the power to hit any point on earth from any other point on its surface in a period of time better measured in minutes than in hours, we are going to be extremely reluctant, of course, to make that same trip by a new longer way, out to the moon and back. The moon has an arbitrarily limited, distant path. Why should that particular region out of all space be so specially useful in a clash between two nations that occupy and

contest the surface of the earth? A 2-dimensional analogy will help to understand the 3-dimensional space problem which now confronts us. If the earth were covered everywhere by ocean, with the exception of a small island containing 2 opposing groups, we might imagine that the ocean around the island would be used for transfer of people and things between the 2 groups in peace and war. Part of the ocean, at most a few times the area of the island, would be used. It is not at all clear that either of the two groups would have anything to gain by seeking to control some part of the ocean very, very far away, even if there were a little rocky bluff sticking out at some distance that might be occupied at great effort by the other group.

To those who think of the moon as looking down on the earth, it can be pointed out that from the standpoint of the moon it is we who are above it. The concept of high and low ground is obviously a relative thing, and when we start dealing realistically with 3-dimensional space and recognize that "the earth is round" and that the moon is many earth radii away, we begin to see how wasteful of resources could be an attempt to involve the moon in our plans for self-protection just on the basis of a hunch extrapolation.

Of course, if the moon or one of the other planets becomes some day a source of vital material without which we cannot maintain our position as a nation, then obviously we cannot be without the means of obtaining that material while our rival goes about monopolizing it. Only research can disclose such a possibility. We have no reason for assuming it today.

If the Russians "take" the moon, it could be the same as their having added something to that large section of ground presently under their control, known as Siberia, only the additional new Siberia will be very much farther away, very much harder for them to reach, so that anything and everything they do in connection with trying to make that real estate useful to them will put a strain on their total capabilities. The effort might swing the strength balance more in our direction than away from us.

There is, of course, the aspect of psychological warfare introduced by sputnik. So long as the world is going to be influenced for or against our way of life and for or against our leadership, in proportion to our apparent scientific superiority over the Russians, just so long must our research efforts include demonstrations to the world of our scientific prowess. Space explorations and space research are strong candidates for this kind of psychological warfare. But there are other spectacular fields. We might do as much or more to prove our superiority over the Russians and gain the benefits of worldwide respect and admiration if we were to cure most forms of cancer It might cost less than putting a man on Mars. It would also imply a new military capability, because any nation that can cure cancer ought to be able to provide new terrifying forms of biological warfare with which to frighten its enemies. Similarly, it might be better to put more of our resources into harnessing the H-bomb, providing controlled thermonuclear energy by relatively cheap techniques—theoretical possibilities that only research can change to a practical reality.

We conclude tentatively that we cannot justify man in space based upon its being obviously most important pure science experiment for man's future happiness, or based upon generalizations about controlling the high ground, or based upon this being the only way to conduct psychological warfare with science.

Is there, nevertheless, a requirement for man in space experiments tied to our chances of survival? I think there is. But in order to understand it, I think it is necessary to understand the nature of military technology as it is developing now and as it will take shape during the next decade.

The military experts can list for us a number of seemingly permanent, urgent tasks These include deterring aggression by having an inevitable retaliatory capability to wipe out the enemy's nation immediately after an aggressive act on his part. It means the ability to handle small wars. It means military reconnaissance and intelligence. It means worldwide communication. It means defense systems to minimize the effect of enemy surprise blows.

Planning of such capabilities has now reached a new peak of difficulty. We have rapidly moved to a "total-earth-simultaneity" class of military operations. A number of launchings taking place at one point on the earth's surface can wipe out a nation many thousands of miles away, in minutes. A military operation now appears to require considering the entire earth as a network of men and machines, all integrated in a huge complex of automatic and semiautomatic devices with human operators interspersed throughout the system. Observation, analysis, decision making, and implementation of decisions are all tied together

in an intimate and rapid relationship, even though the myriad of people and equipment covers lots of geography.

If we choose, for example, to defend our Nation by trying to shoot down enemy bombs before they explode, we must be watching the enemy territory by radar and other devices. We must be searching the skies. What is observed must be discriminated and analyzed, information from observations thousands of miles away must be brought together, difficult computations made, decisions reached as to what under our control will rise to the defense, and where. We invest in these systems many billions of dollars, and we place in the hands of these systems our security.

The systems designer—that collection of brilliant military, scientific, and production experts who must translate the military requirements into a workable new man-machine complex—must break down the tasks into its necessary elements, and must understand the capacities, speeds, locations, and characteristics of each vital function of the entire system. They place a bomb here and a communications channel there, call for an electronic computer elsewhere, human brains somewhere else—all arranged to do the best possible job with the available resources.

You will notice that I have spoken about resources in the sense of man-machine partnerships. What we have, to accomplish the military task, are people and things that people can build and operate. When we speak of an automatic system, we never mean one which has no human component, even if in some systems the human being appears to do little more than push the button to launch the whole operation. Realistically, when we divide up what has to be done—observe, compute, decide, move—we find that sometimes a synthetic machine can do the job better and sometimes the human machine is better. The human being has the equivalent of 10 billion electron tubes in his brain. This is millions of times more than the largest synthetic brain, our biggest electronic digital computer. At the same time, despite this tremendous capacity and despite the input and output mechanisms, the senses, and the muscles that tie to the brain through its nervous system, the human brain is unsuitable for certain other tasks. For instance, we cannot add 2 single digit numbers, such as 2 plus 2, faster than, say, about 1 a second. Very often we require that such simple additions be made thousand or even millions of times per second. The brain can be qualitatively superior to the task and therefore improperly used, and yet quantitatively inferior. On the other hand, the brain can look at a complex picture and in a flash of a second integrate the details of that picture with background stored information, and arrive at a conclusion. We can answer in a second whether we recognize someone we have met out of some thousands of people of our acquaintance—something we cannot do so easily with a machine. Man is not able to withstand certain environmental conditions of vibration, or temperature, or humidity, or lack of oxygen, but we can design machines to work under these conditions.

These two competitors, man and machine, win out, one over the other, for individual specific tasks. However, when we come to a very huge weapon system, we find that there are literally thousand of definable, separate tasks. It always happens, and it probably always will continue to happen, that we can best meet the requirements by a partnership.

Granting this, then, let us compare two nations. Suppose one nation considers all the military tasks that it can conceive of in the future. It recognizes them as very complex, requiring a large number of separate components, some human, some synthetic. It prepares to be able to use each kind of component, the human and the synthetic, in every part of the system. It says, in effect, the specific machines and the specific pattern of man-machine relationship to do strategic bombing, defense, small wars, reconnaissance, intelligence, logistics, etc., cannot be clear to us for all succeeding years. What is clear is that we must have the components around which we can develop the best patterns and arrangements. Thus, we must have computers with speed and capacity. We must extend the radar and other techniques to be able to see at the greatest possible distance. We must have engines that produce high thrust, so we can bring instruments or people up to high velocities. We must be able to reach distant points around the earth or away from it. We must develop ever better warheads. And we must become more and more skilled in understanding how to combine all of these elements to do our job at the least cost.

The other nation, the rival, also recognizes the growing complexity of modern weapons systems. It also grants a man-machine partnership, and realizes that new patterns not all evident today will be needed. It equally clearly sees the

race as one for wisdom in the use of limited technical and physical resources. It also sets out to develop the basic components of the machines and the training of the human operators to provide the greatest of flexibility for its weapons system inventors—all this except for one decision that this nation alone makes in contrast with the first: It decides that man will never be needed in space, despite recognizing that for some hundreds of pounds man provides the greatest possible concentration of equivalent electronics and control that nature has yet devised. This nation edicts at the outset that man is ineligible for becoming a space component. It does this because it sees the disadvantages of catering to man, the extra weight needed to bring him back safely and to support him in space, the special requirements on propulsion and trajectories in order to be easy on the man as to acceleration and, moreover, it does this because it is unable at this moment to prove that man is absolutely needed in that role in any weapons system that it can now conceive.

These two nations start out to develop their weapons systems of the future. One group has the maximum of flexibility, the other has some prohibitions. Which will win out?

We do not know. If it were to turn out to be true in 1970 that every weapon system projected by the nation that leaves the man out is as good as any weapon system developed by his rival who is prepared to include man in space, and especially if even the second nation elects after all to leave man out because they prove him more of a handicap that an asset, then it is clear that the nation that made narrow decisions gained. The other, it would appear, wasted some of its resources pursuing something from which it received no advantage.

On the other hand, if weapons systems are invented to take advantage of man in space and one nation has ruled itself out of the race by a premature decision, it will obviously be the one to suffer.

This clearly means to me that the United States must prepare for putting man in space, but that we should do it on a controlled basis What do I mean by controlled? How does anyone tell what is the right amount of effort? The answer, I think, is arrived at in this way. More urgent tasks, that is, those that appear to involve our ability to maintain ourselves in the near future, must be given higher priority. Investigations preparatory to putting man in space should be made first and foremost when they can be made with little cost because they are added to the unmanned weapons system developments which must go on anyway at high priority. Long leadtime items must be started. We cannot afford to be in a position that denies to us for many years the development of man-in-space weapons systems because we failed to start certain parts of the system early. Thus, for example, if man in space and return requires larger thrust than we need for ICBM's, let us start larger thrust engine work now, because we have seen that large steps in propulsion cannot be made overnight. In this way the cost will not be enormous.

The effort will not be a controlled one, and we will not show wisdom in assigning total technical and physical resources, if we launch an all-out crash program for some weapon system that involves man in space, with all of its supporting facilities, production lines, logistics, and training and handling equipment, based only on some general notion that eventually man must be found in space so why not now. In particular, we must avoid fixing on a very specific, firm, completely specified military weapons system using a man in space if there has not been reasonable justification for such a system's being better in some major way than a competitive system that is cheaper and easier to attain, in which the man is left on the ground. Laying a technological basis early for weapons systems of the future is not the same as starting a complete weapons system program prematurely.

And what do we do if Russia beats us to some experiment involving man in space? This is part of a general problem we might as well face up to now as a Nation. The United States is ahead of Russia in many fields, behind in others. It is going to continue to be this way. We cannot simultaneously plan to be ahead of Russia in everything, an end we will never succeed in attaining, and at the same time expect to use our limited resources to the best advantage in assuring our dominance, or at least our survival, on this earth. We simply cannot be first in everything. We should not allow a misguided attempt toward such an objective to keep us from being first in the advances we think are the most important to us.

APPENDIX B

THE POTENTIALITIES OF SPACE WEAPONS SYSTEMS [1]

By Simon Ramo, president, Space Technology Laboratories, Division of the Ramo-Wooldridge Corp., Los Angeles, Calif.

It is difficult to be objective today about space. That the Soviet Union is not a backward scientific power had been clear for a number of years to those who studied the problem from other available evidence, but it was an engineering feat involving outer space that proved it to the world. In the partially emotional environment that now exists, it has become fashionable and safe to have certain views about space technology. There are many who believe and say, for example, that of all pursuits in pure research in which our Nation might engage the most important is certainly research in outer space. Furthermore, some now assume that if a piece of apparatus or a human operator on any mission is required to spend a good part of the operating time of the mission in outer space, then that must be a better way of accomplishing the task than any approach in which all parts of the mission are accomplished within a relatively thin region near the surface of the earth.

Certainly penetrating outer space has a special fascination to the explorer instinct in man. We cannot predict what new laws of the universe will be exposed to us when we remove the handicap of observing through the earth's atmosphere, and we are curious about life on other planets. And, of course, the use of the space above the atmosphere is important to the military as well. The ICBM is a good enough example of that fact.

But it is far from clear that a dollar spent in exploring outer space will buy us more security in the short or the long term that the same dollar spent in other scientific fields also closely associated with military potential. Furthermore, despite the enormous psychological effect of successful space experiments at this time in civilization's history in influencing the people of the world to believe in the superiority of the nation that performs well and early, it is also not self-evident that each dollar or each hour of effort expended on space experiments buys us more of such influence as that same effort expended in competitive projects. It is even unrealistic to talk about our attaining space supemacy—that is, if supremacy means controlling all of the space that surrounds this earth and denying entry into that space to every other nation. This ambition can be ruled out for any nation today, I believe, if not by technical considerations alone, then by a combination of technical and economic factors.

We cannot be first and foremost in today's world in every aspect of science. In particular, in space technology there are so many experiments that are practical to perform, so many attractive systems for military or peacetime applications that can be brought into being utilizing outer space, that any country with substantial resources choosing to work in this field must be expected to conceive and carry out some favored project ahead of other nations. Thus, if we send up many satellites, for worldwide TV relays, general navigation, communications, and mapping, and land instruments on the moon, and orbit around and take pictures of Mars, that still leaves to another nation during this same time period the planet Venus, satellite systems to participate in weather prediction and control, and manned space stations.

Since we must maintain our security in a world in which we cannot be overwhelmingly dominant in every aspect of the technology that affects security, we must be wiser than any strong opponent in what we choose to do with our limited resources. We need the most objective thinking possible, even on matters affecting space. Those of us in the scientific and industrial field who are specializing in problems relating to space technology must put forth facts about the nature of the field, its potentialities, its limitations, the relationship of one project to another—and we must attempt not to prejudge the relative importance of projects in this field as compared with non-outer-space programs. Such comparisons involve judgments that cannot be left entirely to space experts, who should be content with providing the necessary authoritative inputs on the basis of which the decision can be made at a level where all competitive ways of using our resources can be considered.

---

[1] Presented at the Third Annual Jet Age Conference of the Air Force Association, Washington, D C., February 28, 1958

What are some established facts in this space field? Foremost today, and perhaps for many years to come, of all the space weapons is the long-range ballistic missile. There are several reasons for the present and anticipated future special position of the long-range ballistic missile. As a scheme for delivering nuclear warheads thousands of miles away, it introduces such changes in the flight duration and other characteristics as compared with earlier techniques as to influence by an order of magnitude many of the problems involved in preparing for, resisting, surviving, or retaliating against an attack.

But long-range ballistic missiles still would not occupy a role of top, established importance out of all space weapons systems for very long unless they were capable of considerable growth potential. From experiments and analyses well along today, we know how great this growth potential is. In future years we may expect strategic bombing capability by the new long-range ballistic missile approach based on improved or new techniques, which, compared with the first operational capability of such missiles, will have the advantage of greater simplicity, smaller sizes and weights, more reliability, higher accuracies, less cost, and weapons system as a whole lending itself to greater automaticity, readiness, and larger scale production. It would appear that ultimately such barriers as knowledge of the physical constants of the earth, basic properties of materials, and fundamental limitations applying to guidance and propulsion, must set limits on what we can do with long-range ballistic missiles. It turns out, actually, that extensions beyond the present engineering art, now seen to be practical for the future, will meet foreseeable military requirements, without reaching these barriers. At any rate, the cost, performance, and physical characteristics of first-generation long-range ballistic missiles are not today controlled by such fundamental-science limits, but instead by the cumulative effect of a host of individually small, practical, detailed, engineering design, manufacturing or operational problems.

Now, it is inherent in the quantitative relationships amongst payload weights, engine thrusts, guidance accuracies and structure factors, that when long-range ballistic missiles are developed a whole series of parallel or additional space weapons systems developments become completely practical using the existing components and techniques. For instance, the thrust required for Thor, Atlas, and Titan is such as to make possible the launching into orbit of payloads of sufficient size to carry the apparatus required for international TV hookups, weather observation, world mapping, military reconnaissance, early warning systems, navigation stations for further space operations, scientific data collection, and, of course, for orbiting dogs. As to accuracy and control, it is generally easier to arrange to miss the earth and orbit around it than to hit some militarily useful, small area on its surface thousands of miles away. Thus, the ICBM guidance system, for example, is much more than adequate to take care of orbiting requirements for virtually any application that is worth considering from other standpoints. Also, the ICBM solves the problem of bringing a respectably large payload up through and outside the atmosphere to a velocity almost enough for orbiting. Once this velocity range is attained with large payloads, the additional increment of velocity to permit escape from the earth is a relatively easy addition. Finally, the ICBM nose cone encompasses the major physics and engineering advances required for successful reentry back through the atmosphere.

Something similar can be said with regard to the placing of instrument payloads on the Moon or in orbits out to the nearest other planets, Mars and Venus. Again, the techniques of Thor, Atlas, and Titan, and the actual hardware available from those programs, give us almost all that we need. It thus becomes practical to execute a large number of important scientific experiments.

These then are some facts concerning the ICBM's, satellite systems, and closely related space projects, all of which use similar hardware. All such projects can be accomplished relatively quickly and relatively easily compared with the first big step of developing the large-scale hardware, the corresponding techniques, and the supporting industry and facilities.

The situation with regard to manned space flight is somewhat different. As to man's ability to withstand the special problems of space, there is some fragmentary experimental evidence and substantial theoretical basis for the assumption that man can survive extended space flight. But generally speaking, what man needs in space to survive and to insure safe landing on the earth or elsewhere, translates into apparatus complexity and much additional weight. ICBM hardware is somewhat marginal for even the simplest true space flight with a human passenger, and needs to be modified or extended. For a substan-

tial manned experiments, such as landing on the moon and, of course, safe return to earth, propulsion systems substantially larger than or different from the ICBM are required. However, practical means for doing all that needs doing appear to exist within today's body of science.

The foregoing comments on manned space flight are of course applicable only to nearby orbits a moon's distance or so away. In considering the nearest other planets, Mars and Venus, a manned flight, including landing and return, requires a still greater stepup in nature of passenger accommodations and overall weight over the lunar trip, and is thus still farther away from attainment with ICBM hardware alone Still the steps appear clear in the scientific sense, it being largely a matter of choice amongst alternate approaches, and then years of expensive, coordinated engineering effort, as distinct from true scientific research.

There is still another manned space flight possibility that receives discussion and must be listed, namely to the most distant planets of our solar system and even to the nearest stars. Here the distances are so vast and man's life span so relatively short that the hardware and propulsion methods born out of long-range ballistic developments are hopelessly unsuitable. Here, in fact, we need more than inventions. Scientific discoveries are needed in control and conversion of matter and energy so as to make possible steady application of substantial thrust during flights of many years' duration. Specifically, a manned flight to the nearest star would require years of flight, even at near the velocity of light. While we know no laws of science to rule such a voyage out, we also have no such understanding of these same laws as will permit us even to start a design. In fact, no basic physical process is known to us that would enable the flight duration to be less than hundreds of years.

Our discussion so far has emphasized the relationship amongst a number of missile and satellite proposals and other space projects, based on similarity or lack of similarity of hardware and techniques We can also call out some generalizations about whole classes of space weapons systems. For instance, if the altitude of a vehicle is high enough, it encounters negligible drag, and from this standpoint very long flight durations become possible in space. At the same time, if its velocity is high enough in magnitude, and properly oriented in relation to the shape and size of the earth, the vehicle need not fall to earth prematurely because of gravity pull, even though aerodynamic lift is missing. Fortunately, with more or less conventional propellants, and the absence of major aerodynamic resisting forces, high speeds can be attained in space. Speed may be incidental to the real objective in some space-flight missions that emphasize instead long duration of flight. Space offers a new way of obtaining long durations.

Another unifying concept comes about because of the relationship between the size and shape of the earth and the time of passage around it or from point to point on the surface by space vehicles When one nation can set out to inflict decisive damage on another by delivery techniques better measured in minutes than in hours, and in which the distance between launcher and target is a substantial fraction of the earth's circumference, then the military problem obviously forces consideration of the whole earth's surface and a considerable amount of space above it. To carry on warfare with this relationship between distance and time, the military will require of the technician the development of means for observing, communicating with, and physically contacting all parts of the entire surface and the space surrounding it on a minute-to-minute basis. Notice, however, that once an observation post, or a communications relay point, or a vehicle for warhead delivery reaches a distance from the earth of one or of a few earth radii, then little is to be gained and a good deal may be lost in seeking to place these maximum excursions out even farther. After all, an observation point even an infinite distance away sees only one-half of the earth's surface at a time.

An analogy can be made here to an imaginary two-dimensional situation in which we are more accustomed to carrying out our thinking. Suppose the earth's surface were covered entirely by ocean except for a relatively small island populated by two separated groups. We might then imagine a considerable use of the ocean surface near and around the island for numerous missions affecting the internal operations of each nation and war or trade between them. But the need for control of the entire ocean would not be obvious. Now, in three-dimensional space, we have the sun and the moon and the other planets of our solar system. It is understandable that we should want to go out into space, take a closer look at all of these other bodies, make observations, and bring back the information. It is far from clear, however, that control of

earth must necessarily go to that nation which has put more of its resources into escaping from earth's gravitational pull.

Consider, for example, a retaliatory capability for the purpose of deterring aggression. Assume that from our limited resources we choose to assign a certain fraction to such a deterrent capability. If the strategic bombing force is to be a deterrent, then a sufficient portion of the total planned force must be counted on to survive the enemy's surprise blow. Now, such survival can be attained in principle by a number of methods, including dispersal and secrecy as to the location of the retaliatory force, hardening to resist a severe attack no matter how strong, and active defense. The problem is always one of comparing all of these ways on the basis of economics, resources, reliability, readiness, and all of the factors known so well to the military. The use of outer space merely adds additional cubic footage, enormous quantities thereof, to the potential locations of our strategic force. It adds new problems for an enemy seeking to know its location and planning to obliterate it. Technically, we have it as a matter of choice to use a volume that extends from beneath the average surface of this earth out to distant space, to the moon and farther. The more of this total volume we decide to include in our plans, the more costly and complex our weapons system may become. We do not get this additional volume of space for nothing, and it is not evident that resources expended to buy additional volume may not better be used to buy other improvements or guaranties of an inevitable retaliatory capability.

For instance, if our basic technique of retaliatory bombing were characterized by a very small number of warheads to be delievered, we might be inclined to pay a tremendous premium, relatively speaking for the privilege of putting our launching sites at such positions in that volume of space available to us that the possibility of enemy interference with our ability to retaliate would be minimized. But, on the other hand, our retaliatory capabilities might be characterized instead by large numbers, made possible, for example, by developing increasingly simpler and cheaper ICBM's. We might then believe that, despite the relative accessibility of potential launching spaces to the enemy, it would still be highly improbable for him to eliminate enough of this huge force to avert retaliation. Accordingly, we might be inclined to assess the extension of the volume of space available to us as deserving much less out of our overall limited resources.

These and many other considerations deserve high-grade quantitative military-scientific analyses to determine whether space launching sites on the moon or elsewhere constitute the best way to use our budget on behalf of a vital deterrent capability. In any case, certain facts stand out. It is not automatically true that bombing grows better the farther away from which it comes. Things may change so it will some day become obvious that bombing from outer space is the best approach. We must be in a position to exploit a new possibility, and we must therefore assign some of our resources to the problem. However, let us carefully distinguish between an urgent program of experiments, analyses, and early explorations intended to find out an answer and be ready for new requirements, on the one hand, from a crash program to develop a complete system based on the idea that the answer is self-evident.

Of course, what has just been said about strategic bombing and deterrent capabilities is equally true about weather control, communication systems, and the like. In every one of these instances, there are competitive ways of spending the Nation's resources in an attempt to achieve the same ends, and the problem always includes making comparisons. In fact, realistically, the biggest costs of most of these systems are in the ground-based rather than the space-based components. Generally these proposals involve a system of much new, complicated, automatic gear, widespread geographically, with advances required in information transfer, interconnection, and control to make the operation practical. Much of the development, and hence of the planning and comparing, needs to go into these overall system considerations if most space weapons systems being proposed are really to be judged seriously.

A certain general argument needs now to be described. It starts by recognizing that weapons systems involving vehicles in space can be of military value, and, moreover, even if only for scientific data gathering the data strengthen the nation that collects them. Accordingly, it would appear to be of interest to a competitive nation to seek out and destroy any space vehicle of its potential enemy. At least doing all required to make possible clearing space of the other's vehicles should be considered—this even if it means sending up a more costly space follower to be paired off with and be prepared to destroy each entry

into space of the rival. Of course, this game readily leads to more and more complex systems with space-located subsystems of increasing scope and variety, and encompassing more and more of outer space. The problems of detection, interception, data handling, decisionmaking, and communications will eventually involve the introduction of automated operations and man-machine relationships on a new scale. As a technical man, I am inspired by the continuing challenges all these steps and countersteps will present. Here truly we have a limitless candy store. However, the ratio of contribution to security to resources expended could reach a new low. As a citizen I hope it will turn out that inspired handling of international affairs and military strategy can somehow avert that kind of space age. But, if it has to go that way, our present hardware and techniques give us a solid beginning, and we can build on it at a pace limited by the technical and physical resources assigned.

Clearly, planning space weapons systems presents us with a new predicament. We should like to be logical and assess the true military value of a space program. But what good does it do to say that the moon may be an unnecessarily far and otherwise unhandy place from which to launch an attack or to prove with factors to spare that if another nation chooses to direct bombs at us it can be done more cheaply and with greater certainty from bases on earth? Would the United States public be content if the Soviet Union were established with anything whatever on the moon and we were not? Nor can the technical body furnish a sufficiently strong reassurance that the moon and outer space in general are just so much more Siberia. This is because we may indeed find useful new matter or phenomena on the moon, the sun, or the planets, and, so the argument goes, we cannot allow another nation to discover these things ahead of us because they will then be superior in science and, ultimately, will have a superior military capability. It is not that future scientific research is held up by a crucial, bewildering scientific enigma which can only be answered by space flights. The situation is more general.

Here is a region of unknown, and experience shows that whenever we explore the unknown and it becomes known we find additional scientific principles and useful applications.

In this general sense, we again notice that space research should really compete with other forms of research, but it is more than most involved with the problem of psychological warfare. The Russians' sputniks have influenced world affairs. A space experiment has the advantage of being conspicuous. It excites the imagination more than the average quiet research on other aspects of nature closer to earth. It is not that space research is the only glamorous research area. There are others that could well have convinced everyone that Russia's scientific powers had been underestimated. Suppose, for example, that Soviet Russia and not the United States had produced the answer to polio, followed quickly by a universal cure for cancer. In addition to concern over such evidence of possible Soviet superiority in biological and medical sciences, many would quickly point out military implications as well. That is, it might be feared that any nation that knows enough to stop cancer could threaten us with a mortal, new form of biological warfare. On top of this, let us imagine that Soviet science turned up well ahead of us with important new and basic developments in the field of controlled thermonuclear energy. It may be that a given amount of our technical resources assigned to the space field will do more for us in the world public mind in showing our relative standing as a great scientific power than an equal amount of money spent in any other field. If this is true, I trust that the right people are comparing the alternatives and will make the right decisions, because it is not enough to hear from the space engineer in order to decide the issue.

In summary then, we must label the long-range ballistic missile as a vital weapon. Certain orbiting and related space weapons systems are potentially vital and merit top priority even though at the same time deserving of objective comparisons with alternate ways of doing each military mission. As to escape, exploration of outer space, control and patrol of it, and scientific data collection to learn more of the life and phenomena of our solar system—it is harder to prove that these fields are vital to our security. There is a possibility that if another nation leads in these areas and leads sufficiently, it may eventually discover such new science as will cause it to invent weapons systems giving it decisive advantages for control of this earth. Because of this concern, and because of the worldwide psychological effects of any other nation having a superior scientific position, space research and space exploration appear to deserve a large budget, a high priority, and wise planning so that at each stage

of the probing into space good use is made of the knowledge and the hardware the earlier stages have made available to us.

Those who must make the overall decisions will make the best ones, in my opinion, if we distinguish the clearly vital space weapons systems from the intuitive feeling that man must ultimately make a conquest of space. From now on, it is going to be increasingly important to insure that wisdom accompanies imagination. The earth may not be inherited by the nation that first escapes from the earth on a grand scale, but rather by the one that does it just often enough and does a lot of other things besides.

ICBM: Giant Step into Space

Here for the first time, is an authoritative account of the entire AF long-range ballistic missile program, its relation to past and future developments in terms of management and technical know-how, and an explanation of how it can make the conquest of space a reality

By Simon Ramo, the Ramo-Wooldridge Corp., Los Angeles, Calif.

The long-range ballistic missile program of the United States Air Force represents the largest integrated technical development program ever attempted by this country. It involves a simultaneous extension in practically every phase of the guided missile art. Compared with previous developments, it means higher thrusts, larger weight-to-structure ratios, higher speeds, higher accuracy and greater versatility in guidance and control, higher rates of burning of propellants, higher temperatures and greater expansion of facilities and industry capability in a short time.

The purpose of this article is to discuss, as security restrictions permit, some aspects of the USAF intercontinental ballistic missile (ICBM) and intermediate-range ballistic missile (IRBM) projects. In particular, an effort will be made to relate these developments, in terms of management and organization, as well as scientific-engineering concepts and actual hardware, to past and future developments in the missile field.

The Air Force ICBM program has a decade of background. The decision to broaden the effort and give it top priority was made in recent years, but development began some 10 years ago at Convair Division of General Dynamics Corp. During that period, scientific feasibility and military requirements were in proper harmony in a relatively small program looking to the fairly far-off future. Then changes in both the technical art and military needs combined to dictate an unprecedented effort to obtain the earliest operational capability.

Characteristics of Guided Missile Development

But there is a decade or more of guided missile experience covering a multitude of other projects as well, some of which have become operational. It will probably be helpful to summarize some general characteristics of guided missile development apparent when the accelerated ICBM program was planned, before discussing management and engineering details applying to this specific program.

Of course, it is clear that a program of this type must include a large technical effort to develop and design all the components. And, for such development work to be completed satisfactorily, hardware must be built and tests made that confirm the workings of the entire system. What has been less than completely obvious in some past developments is the extent to which the whole developmental plan must hinge around certain practical factors.

The research and development plan must be based on careful matching of military requirements and the state of the art. The easy approach is to assume, from some "semi-hunch," qualitative considerations, both the military requirements and the supposed state of science and engineering. A more difficult approach, but one which can literally save years in attaining a useful end result, is to recognize that both the military requirements and the technical art are complex issues requiring careful interpretation and the consideration of many parameters on a quantitative basis, with full account of their reciprocal effects. To obtain a real payoff in time and resources, the task must be faced up to by a proper team of military and technical experts brought together for steady and objective influence on the research and development plan.

The picture of a guided missile program in which only one missile is assembled and taken out to launch, with the chief scientist and his sole assistant waiting with high hopes for a confirmation in final flight test through this single definitive trial, is for the comic books, and not for a realistic world. A single or a few shots of a missile, built breadboard fashion by its inventors in a closely supervised model shop, may be a satisfactory approach to illustrate a principle. More often, in guided missile development, the step being taken from the technical standpoint is essentially beyond question as to its scientific basis. The key problem is to so organize the program as to assure the efficient working out of all the engineering details, some in theory and some by experiment; the attainment of reliability through a great deal of testing; and an industry capability to reproduce the results in the quantities required for a military force.

How early production planning can be started is special for each guided missile project. It is a function of the newness and complexity of the engineering and the relative risk of having a delay while production is planned after the development is completed, as against having to re-do production tooling or manufactured components if the late stages of development disclos that substantial engineering design change is needed. However, in any case, it must not be overlooked in the development of a missile that production and operational capability are the real end goals of development.

In the past, reliability considerations have not been in the foreground often enough. Clearly, a complete missile system cannot be very useful in a national emergency if it is likely to fail in some important respect more than a small fraction of the time. But the complete system consists of many major subsystems, including, of course, much more than the vehicle itself, creating further problems.

Suppose we ask for a modest 50 percent chance that the complete system trial will occur without a malfunction of some major subsystem. For simplicity, let's say there are 5 or 6 of these main subsystem elements, with an equal chance that 1 of them will function improperly during flight. Then, to have a 50 percent chance for a completely successful flight, each of these subsystems must be counted on for roughly a 90 percent chance of operating perfectly.

But each of these subsystems itself consists of hundreds of critical components, which must then have an average reliability during flight in the 99.9 percent region, with a failure of only one in a thousand. Even if each of these components is laboratory tested, improved and retested innumerable times, this must be followed by systems testing to determine the interactions of one component on another when working in an ensemble, and then by flight test because of possible reduced reliability owing to environment and unknowns in actual flight that no prior simulation or analysis can dependably reveal.

CANNOT RELY ON FLIGHT TESTS ALONE

Typically, missile flights are measured in minutes. A flight-test program, especially in its earlier stages, reveals only fragments of data for various parts of the complete trajectory. Hundreds of flights may be needed to accumulate a single hour of operating experience. It is apparent that the attainment and the proof of reliability, somewhat different considerations, cannot rely on flight test alone, because of the enormous expense and the relatively small amount of data obtained Wherever possible, all subsystems must be brought to high reliability by ground tests. The complete systems test must be used for that class of problem in which interactions among all parts of the system and the true environment of flight are the added problems.

This does not mean that the first flight test should be delayed until testing on the ground has caused all elements to reach a stage of reliability where nothing remains but these final interactions and environmental problems. Flight testing in its initial stages obviously is carried out to uncover interaction and flight environmental problems as early as possible, even if it is a virtual certainty that the first flight tests will be handicapped by unreliability of components.

Thus, the final ground development of all subsystems and components for the goal of a successful operational flight depends partially on the results of earlier imperfect flights. Complete systems tests, including missile launchings, constitute the only way ultimately to completely confirm the soundness of system design. But the first flight tests are so likely to be plagued by the accumulation of many detailed shortcomings of the whole operation that they might mask a fundamentally wrong system configuration, if such a misconception in design philosophy actually existed.

RELIABILITY AND GOOD DESIGN

The important lessons from the past include the fact that reliability does not come naturally as the result of good design. An engine will not provide a specific thrust just because it is well designed. It must be designed for that specific thrust. And no matter how well designed for 1,000 pounds of thrust, it is not likely to give 100,000 pounds unless so grossly overdesigned as to constitute a poor engineering choice for the original requirement. Similarly, a particular component is not going to give 99.9 percent reliability unless it is designed for that from the beginning, and we are not going to know whether it has that reliability unless we have a planned program to prove it.

Programs of the past have included some that have lacked sufficient hardware to make possible any satisfactory approach to reliability testing. Other programs have been so optimistic as to the number of units of the system that could be used to advantage that they suffer from indigestion, with shops busy making parts whose workings have not been sufficiently well understood and whose test program, both as to technical manpower and facilities, was inadequate to make use of the hardware as a means for finding design weaknesses. Planning the amount of hardware for each stage of the program, from the beginning of component development and reliability checkout through to final systems testing and initial operational capability for military use, is a major factor in setting up and maintaining a good development program for a major missile system.

There is probably no characteristic of major weapon systems programs that has so often in the past been the determining factor in the speed and efficiency of development than the facilities program. The tendency all too often is to fail to include all needed facilities, or to underestimate the lead time required and the technical difficulties of such facilities programs. Major facilities acquisition also involves difficult arrangement-making problems between various Government agencies and between such agencies and industrial contractors. Recognition of the size, scope, and complexity of facilities problems is a prime requirement for the successful execution of a major program.

TENDED TO FOCUS ATTENTION ON BIRD

During part of the decade now behind us, there was a tendency in some missile-development programs to focus attention almost entirely on the bird. In general, there is a myriad of other equipment that must be designed and other problems that must be dealt with to make for a military operation. Checkout equipment, handling and training equipment, organization of operational bases, logistics, and human engineering factors—all are needed to complete the list. The design of this equipment and attention to the array of procedural and other problems that go with a complete weapon system cannot wait until there have been successful demonstrations of the flying subsystem. Obviously, it is not good systems engineering to freeze one part of the system until attention has been given the other parts. In addition, the desire for early operational capability means all parts of the system must be started early.

NATION'S RESOURCES CALLED UPON

From the beginning of the accelerated ICBM program, it was evident that questions of management, philosophy of overall approach and organization would need a special kind of attention. Moreover the total effort, if carried out successfully in a relatively short time, would involve a costly fraction of the Nation's scientific and material resources. The simultaneous advances required for the present program in all aspects of guided missile system art made clear that large facility, hardware and reliability testing programs would be needed. It was obvious that the entire program would have to be widespread geographically and would require contributions by large numbers of organizations. It would also have to be unusually well organized and highly supported on a good management, as well as scientific, base. These operations could not be left to trial-and-error or hit-or-miss experimentation.

Certainly few, if any, programs have had and continue to have the advantage of a deeper study of the relationship between military requirements and technical possibilities. Time, performance, and resources compromises are always necessary in merging a military need with technical and industrial attainment. But in the present instance, it simply has had to be a lot better. Top military and technical minds of the country have been joining to create and maintain research

and development, production and operational plans with the least doubts as to the fundamental soundness and proper timing for each step.

Of course, any program comprising a vast number of interrelated steps cannot be precisely laid out ahead of time. Moreover, some steps must depend on progress or data obtained in earlier ones. But the objective has been to plan a program that will have a minimum chance of hinging upon any greatly speculative technical issue, and, equally important, upon any questionable evaluation as to the ability to carry out development and production as required.

A fundamental part of the plan for the earliest possible attainment of both long- and medium-range ballistic missiles has been to make maximum use of all past developments in technology, as well as all of the Nation's existing facilities. For essentially every important aspect of the overall program, it has been clear that more than one approach is technically and industrially feasible. However, to predict which of these potential approaches would lead to the others timewise is not always possible. Also, the importance of the program requires insurance against errors in human judgment. For both of these reasons, a certain minimum number of parallel approaches was considered essential in most areas.

Step-by-step into space

Range (nautical miles) (optimum trajectory)	Altitude at apogee	Cutoff or escape velocity
	Nautical miles	*Ft./sec.*
200	70	3,000
1,000	350	11,500
5,000	600	22,000
Satellite	(300)	25,000
Moon		35,800
Mars		36,500

But there was still another reason for bringing in two major contractors to cover independently most basic subsystems—namely, the amount of effort needed for detailed design, testing and production planning. This huge workload—the different types of ballistic missiles to be developed, the numbers and kinds of needed facilities, the locations of various industrial organizations with respect to areas suitable for testing subsystems and to long-range testing bases—all made clear that for almost every aspect of the job it would be necessary to bring in more than one top organization to share the load. The division of the work was made among a large number of industrial organizations, Government agencies, universities and private foundations, all selected by the Air Force and assigned to specific program segments on the basis of their experience and their technical, physical and management resources.

HOW MISSILE TEAMS WERE SELECTED

With duties in ground-support equipment, training and handling added to the production effort, and all having to be started prior to the completion of the research and development program, it was seen to be advantageous to select for key development projects those organizations in the Nation capable of continuing through to production and operational equipment support. More specifically, it was felt that team members that would ultimately dominate factory testing of production articles to be delivered to operational units should be the ones to make the first experimental tests on embryo equipment.

Separate teams were set up for 3 missiles, with the 3 aircraft team members (Douglas on Thor (IRBM), Convair on Atlas (ICBM) and the Martin Co. on Titan (ICBM)) given the jobs of physical integration of the subsystems into the missile structures and systems testing. The setting up of these three projects has been an efficient way of combining the need for a certain minimum of backup approaches with the equally important requirement of assuring tight integration of subsystem tasks into a harmonious ensemble to meet military requirements.

The parallel efforts had to represent different approaches, yet had to be complementary and of maximum aid to one another. For instance, the propulsion system for Titan should also work for Atlas; the nose cone of Atlas should be operative on Titan. Further, it was frequently necessary for these programs to utilize common contractors. Thus, with the exception of

the airframe contractors, the IRBM program uses subsystem hardware and contractors from the Atlas and Titan programs. All three programs use common Government facilities to a considerable extent, including common flight-test ranges.

The very size and cost of the whole program exerts a control on the extent to which parallel approaches can be tried. Although every effort was made to plan these programs so as to utilize the existing art, and thus eliminate uncertainty as to success, the boundaries between what is known and unknown in the technical art are being regularly pushed back by supporting research efforts designed deliberately to provide a substantial safety factor for all three projects. Wherever there is any major question as to which approach is the best, this implies that the results from one team's effort should be allowed to benefit the work of the other teams.

All aspects of organization—selection of contractors, distribution of responsibility among them, setting up of teams—were based on the objective of earliest operational capability. However, it was only realistic to recognize that the projects would continually need evaluation and modification so as to minimize any threats to success and to exploit any newly acquired information. Also, no program requiring so many new facilities, from special environmental equipment to elaborately instrumental ranges going out thousands of miles, could be planned initially with such foresight that detailed alterations of plans would never be needed. In fact, to try to hold to such an objetcive could be a great handicap.

COMMUNICATIONS WEB WAS NEEDED

Accordingly, it was seen that the central management organization would not only initially require sufficient scientific and systems engineering strength to work with the military in the creation of the research and development plan, but would also have to be in a position to control any major aspect of the program in the light of what was happening at any given time. A web of communications needed to be set up, converging in one central source competent to evaluate the information and to provide proper direction to all team members. Even the initial relationship between military requirements and the performance specifications would require regular reviews, and modifications to attain an earlier result would always have to be weighed against a competitive method using a later but superior result. Planning, monitoring, and optimum assignment of facilities was seen also to be a major effort for the central management organization.

WOULD HAVE PRIME RESPONSIBILITY

Moreover, in view of the plan to parallel the research and development with production planning and complete operational implementation, it was evident that a large amount of central management's internal activities would have to do with interactions among the technical, operational, and procurement aspects. Above all, it was clear that a systems engineering organization would be required to do systems design and analysis and to exercise prime responsibility for overall performances that meet the military requirements.

The communications problem for so large a program presents a real challenge, and a great deal of attention had to be given to arranging the program's operations so as to minimize this disadvantage. An important compensating factor has been the centralization in one geographic location of the Air Force authority and control, embodied in the Air Force Ballistic Missile Division, ARDC, as the executive agency, and the Ballistic Missile Office, AMC, as the procurement agency, together with the systems engineering and technical direction organization—the guided missile research division of the Ramo-Wooldridge Corp.—in one set of buildings, with higher echelons of Government supporting and decentralizing to this program-management team.

PREVIOUS ART WAS USED

Some general remarks relating the ICBM and IRBM technical problems to those of other missile programs may help to show how advantage was taken of the previous art. Roughly speaking, the counterpart, in the sense of a previous technical step, can generally be found spread over the entire guided missile, aircraft, and electronics art. Thus, a ground radar that had nothing to do with guided missiles in the past furnished the basis for an extension for some of the ICBM system. Something similar can be said with regard to ground digital

computers. Some techniques and components came out of aircraft, others out of short-range ballistic missiles and still others from surface-to-air and even air-to-air missiles.

The illustration on page 41, which shows to scale a few of the trajectory characteristics of ballistic missiles for 3 ranges, taking a 5-to-1 step each time, from 200 to 1,000 to 5,000 nautical miles, suggests that some very substantial differences should exist between short- and long-range missiles. On the other hand, a number of factors do not change very much between very short- and very long-range missiles.

In making the major technical decision, a notable effort was made to bring in the experience of all the leaders of the guided missile and associated art. As an example, for the testing plan, experts from earlier programs either joined the present one or were brought into key discussions. Some believed the best way to move rapidly was to analyze every test completed and to use all the results to make improvements before attempting a next test. Others argued that, without a set of tests that would provide statistical and confirming evidence of faults, no solid progress could be made. Many had experienced their worst problems in the past when they tried to reproduce results and wanted special emphasis on catering to the fabrication and assembly problems from the outset. Others felt substantial redesign could be tolerated. Judgment as to technical risk in skipping steps to save time varied, of course. But we had the assistance of most of the experts and the facts of the past to help us.

To give adequate credit to personnel and organizations who have or are now participating would require a separate article. Suffice it to say that practically every aircraft, electrical and electronics organization, Government laboratory and agency, university and nonprofit foundation, was consulted, and that most are either participating or have furnished data and experiences for consideration.

PAST EXPERIENCE INTERPRETED

All of these past experiences naturally had to be interpreted in the light of our specific problems. Many approaches that looked good on other projects were seen to be less than optimum for this one, because the priority and support of this project made possible even better avenues that would not have been possible elsewhere.

Now let's consider specific technical fields. First, propulsion. The need for large-thrust rocket engines is clear because a long-range ballistic missile of operational usefulness must bring heavy payloads up to a power cutoff velocity of 15,000 to 25,000 f. p. s. However, such rocket engines had been under development for about 10 years by the Air Force at North American's Rocketdyne division for use in both long-range ballistic missiles and long-range strategic missiles of the air-breathing type, in the latter case as boosters.

The propulsion program has since been expanded to include other pioneer organizations, with Aerojet-General as the major added contractor. American Machine and Foundry is a principal contractor for auxiliary power supply.

When the Air Force ICBM program was accelerated, this engine work was seen to provide the best possible basis for extension and rapid reduction to practice. As a matter of fact, components of the ICBM engines provide the propulsion system for IRBM missiles as well, with both the Air Force Thor and the Army Jupiter IRBM using these identical engines from the same production line. Thus the manifold expansion in resources which the ICBM program had earlier placed in motion to accelerate the availability of these large rocket engine components was a major factor in the determination of estimated schedules for the IRBM programs.

For thrust control of the ICBM and IRBM, both as to cutoff and thrust vector orientation, use was made of the background experience of various organizations in the country. In particular, a basis for the swiveling of the rocket engines to control thrust vector orientation was provided by the Air Force's work on the project MX-774 surface-to-surface missile, performed by Convair, and on the Bomarc surface-to-air missile, performed by Boeing, and also by the Navy's Viking program for upper atmosphere research, performed by the Naval Research Laboratory and the Martin Co.

Structure problems with long-range ballistic missiles are severe for several reasons. Keeping structural weight to a minimum is much more critical than it is for most other flight vehicles. In addition, the structure must withstand high accelerations and speeds, and extreme conditions of air density and temperature, and high Mach numbers are reached in regions of substantial air

density and with considerable temperature differences between the outside and the inside of the structure.

The structural problem is somewhat less severe in the case of the IRBM. Of course, it is possible to design a short-range surface-to-surface ballistic missile so that the structural weight is very critical, with the range falling off badly from the design requirement when and if the structure has to be made somewhat heavier because of unanticipated problems. However, as a function of range, it is very much easier with today's art to overdesign rangewise for the shorter range ballistic missiles. As one increases the range to intercontinental proportions, it becomes increasingly more difficult to choose all the other parameters so as to allow for generosity in the assignment of weight to the structure itself

FACES SIMILAR PROBLEM

The problem has considerable similarity to that of the long-range, high-speed airplane, where the designer also reaches a situation where a small difference in structure can make a large difference in performance of the aircraft.

The detailed design of such large, lightweight structures and the physical integration of all components into the structure have been part of the successful operations of aircraft companies for years. It is not surprising that the Air Force has chosen some of the most experienced of these companies to handle the structure and physical integration role.

The guidance and control problem for the ICBM is similar to that for certain surface-to-air missiles, as well as shorter-range surface-to-surface missiles. In a ballistic missile, the problem is to attain the proper vector velocity at the end of a relatively short powered flight path. Whether this is done by measuring the motions of the missile with onboard accelerometers mounted on stabilized platforms, or by the use of radio measurements made from the ground, or by some of both, the problem is similar to that of a surface-to-air missile which must traverse a limited region of space with the proper timing and velocity to intercept its target.

Of course, there is great similarity between long- and short-range ballistic missiles. But one must be careful here in making the extrapolations, because in general the instrumentation errors as seen at the target grow much more rapidly than with range. Also, the distances for communication from ground to missile can be very substantially greater, so that the communication components do not necessarily have the range to permit them to operate with comparable performance, if at all. A gyro carried by the missile has less time to accumulate a drift error in the shorter boost time of an IRBM than is true with an ICBM. In addition, for the same accumulated drift at the end of powered flight, the error is greater at the target for vector range.

COULD BE APPLIED TO IRBM

Thus, certain guidance and control components that were already under development for the ICBM could be readily applied to the IRBM with a relaxation of component performance specifications.

Radar and computer equipment has been an important aspect of the defense program of the military services for many years. Some of these major contractors, including General Electric, Bell Telephone Laboratories, Western Electric, Sperry Rand, and Burroughs, are now engaged on behalf of Thor, Atlas, and Titan.

Other projects have furnished substantial background on precision inertial components. The requirement for low drift in the gyros, for example, arose in previous long-range strategic bombing and navigation work, both for manned bombers and jet-propelled guided missiles. In such past developments, the gyro drift rate had to be kept exceedingly small so that the cumulative effect for the longer flight time would not impair the final result. In the case of the same miss by a ballistic missile and by an aircraft-type missile of intercontinental range, for example, it is the latter that requires the higher accuracy in the sense of freedom from drift, by a factor of more than one order of magnitude.

Of course, gyro drift is not the only, or even the major, source of error. But it could be a major source if we were not in a position to apply available high-grade precision gyros that have been under development for many years for aircraft systems as well as missiles. Fortunately, the same inherent mechanical design features that free these instruments from error also make them very rugged. They do not fall apart under the higher acceleration of the ICBM. Several organizations that have had a decade of successful experience with pre-

cision inertial components and stabilized platform work are now heavily involved in the Thor, Atlas, and Titan programs. Among these are the Instrumentation Laboratory at MIT, AC Spark Plug Division of General Motors, and Arma Division of American Bosch Arma.

To say that the ICBM reentry problem is unrelated to any past developments is an overstatement, of course, but let us take it as a starting point. Initially, we had no experimental results on any missiles or airplanes for the required ICBM conditions. The problem here includes one of high heat rate, but for a short time. Not even meteorites provide us with comparable data, although some useful clues can be obtained from them.

The problem was first attacked with an intensive theoretical exploration of the fundamental processes involved. This effort, one can say with only slight exaggeration, enlisted the combined hypersonics and heat transfer talent of the Nation with background on the problem, through direct involvement with the leading workers in many universities, Government agencies, and industrial organizations, including especially NACA and the California Institute of Technology.

Theoretical extension of such experimental work as existed, mainly for lower Mach number conditions, next suggested experiments to confirm the theories, and these were set up in several organizations. To date, highly significant experimental work has already been accomplished on this program by Avco with large shock tubes and by Lockheed with multistage reentry test vehicles. These experimental results have confirmed the extended theory and provided the basis for reentry vehicle design. "Nose cones" for the vehicle are being developed and produced by General Electric and Avco

Included in the experimental work was a series of multistage test missile launchings (12 perfect flights occurred in succession), from each of which comprehensive and important pioneer data on reentry were obtained.

Of course, all missiles, except perhaps some subsonic ones, encounter the problem of heating, and for some the heat rate is so high as to require major attention. However, the problem can be minimized by proper choice of parameters in the short-range ballistic missiles, for example, and in most surface-to-air and air-to-surface missiles. It is safe to say that use was made of every bit of pertinent experimental data and every applicable formula that could be found as bases for extrapolation to the unprecedented ICBM situation. For the IRBM, the problem is easier, but still much tougher than for missiles in general.

MAKES SPACE CONQUEST POSSIBLE

The relationship of the ICBM to future developments is partially indicated by noting the power cutoff or escape velocities, required for short, medium, and intercontinental ranges, for earth satellites, for reaching the moon and for reaching Mars, indicated in the table on page 41. We see that each velocity requirement differs by a decreasing percentage from the next slower one. The ICBM, with its capability of imparting a high velocity to large payloads, essentially makes space conquest possible. Insofar as propulsion and velocity are concerned, future projects appear to be almost attainable with ICBM hardware merely by reducing the payload somewhat.

As for the accuracy of guidance, something similar can be said. It is easier to hit the moon than to hit a militarily useful target several thousand miles away from the launch point. The ICBM can therefore be considered a major step toward true outer space technology, especially if one limits consideration to unmanned payloads.

Something too often in the background in space technology discussions is the problem of getting from the surface of some planet, say the earth, out to space and getting back down safely through the atmosphere. What happens in empty space, which takes up most of the flight time, may always be less important from the engineering standpoint than what happens in getting up through the atmosphere to the necessary escape velocity and in getting back down. In these respects, the ICBM is solving a major fraction of space technology problems for unmanned instrumented flights. This would not be the case if the ICBM payload were small for there is a great difference in difficulty and in complexity of task as a function of size of payload. The ICBM payload is large enough to cross over into the region of maximum interest.

Another future step increasing payload requirements even more would be to have human passengers carried through distant space, especially in relatively short times. Because of the passengers and all their equipment, and also because of the indirect problems associated with the length of time of such flights, the increase in payload probably will be one order of magnitude over the ICBM.

Furthermore, because ICBM accelerations are much too high for human passengers, the large ICBM engines would have to be controlled and throttled in a different fashion.

MAY MAKE FOR FASTER PROGRESS

If we seek space conquest for scientific, commercial, or military purposes—whether for world TV relays, weather prediction, or cosmic ray or other physical measurements—certainly this can be done earlier and probably more economically with unmanned, instrumental vehicles. If at present we concentrate on instrumented space vehicles, instead of on those carrying passengers, we may conceivably make much faster progress in space technology. The coming space age may largely deserve to be an instrument-passenger kind of era. The space age may come faster if it is so recognized.

The foregoing remarks about the future, based on ICBM experience and accomplishments, have touched mainly on technical state-of-the-art advances. What of management and organization? Does the present kind of unique management setup offer a solution to the problems of how to get large systems engineered and directed?

The writer can only give his own opinions. One of them is that "there is more than one way to skin a cat." Not every big project would appear to need a special management-systems-engineering group such as exists for the AF ballistic missile programs. More often, the systems engineering task can be effectively carried out by one of the major industrial contractors engaged in producing part of the system, perhaps an aircraft manufacturer if the system hinges on aeronautical or structural aspects, or an electronics manufacturer if transfer and control of information are the critical aspects. At other times, the answer may be a group of associate contractors, with the systems engineering held by the Government.

For the present management-technical-direction scheme to be appropriate on some future project, some of the exceptional conditions that brought the present one about would have to reoccur. These would include a crash effort requiring many large, competitive industrial firms; exceedingly broad advances in the technical art, radical change in military operational techniques brought about by the new system, overlapping of development, production, and operational preparation; urgency justifying high priority in channeling of resources; and major, widespread, and novel Government facilities. Under these unusual circumstances, the present AF arrangement, combining under one roof a capability for overall management, procurement, systems engineering, and technical direction, for visibility and evaluation of all progress, for analysis of performance versus requirements and for assessing technical risk versus funds and urgency, would appear a good way to do the job.

The cost of systems engineering and technical direction on the ICBM and IRBM programs is about 2 percent of total costs. It will be an even smaller percentage when later production costs are added after the systems engineering is finished. Whatever arrangement is adopted for any future project, the quality of the systems engineering and the objectivity and competence of overall technical direction obviously can have an effect on the result far beyond the cost of these tasks.

Evidently the organization of the direction of any important project merits considerable thought.

The CHAIRMAN. Mr. O'Brien, do you have any questions?

Mr. O'BRIEN. Does not what you have said spell out in the long run the establishment of a Cabinet post of Secretary of Science to provide the adequate umbrella you have in mind for all of these scientific endeavors?

Dr. RAMO. I think it well might.

Mr. O'BRIEN. I might say from the testimony we have had I think the military people did a terrific job and filled a vacuum which might not have otherwise been filled and I do not think they overlooked the basic research at all; it is a question of degree, but there is a possibility that the Defense Department might from time to time, because of the urgency of its own responsibilities, subordinate that which could lead quickly to the peaceful uses of the unknowns.

Dr. Ramo. I think that is exactly right, yes.

Mr. O'Brien. Would it be your idea that for the time being we might create some agency such as that in the bill, or give the power to some existing agency and then in the long run work toward the establishment of that overall office with a general recognition of science in the peacetime field, as well as the military?

Mr. Ramo. And may I say that again in my own words?

Mr. O'Brien. Yes, I wish you would.

Mr. Ramo. I believe that looking back and looking ahead that we have evidenced in the past and we have reason to fear in the future that as a Nation we may not do enough pure basic research that is well removed from any immediate military capability.

Mr. O'Brien. That is what I had in mind.

Dr. Ramo. We must find means for assuring larger research programs.

On the other hand, we must be certain, in the process, that we do not say to that part of the Government which has responsibility for the military that it is precluded from doing one or another type of research whenever it feels that that research is already pertinent to a military capability.

Mr. O'Brien. Under the Secretary of Science again, you might have a situation where the military was engaged in something that was purely military, but in the process would uncover something that could lead in the long run to a major peacetime development.

Dr. Ramo. Exactly.

Mr. O'Brien. That would be the point where the Secretary of Science could step in and see that little idea did not die aborning and was given a chance to develop more rapidly than it might if it was just riding along with a major military project.

Dr. Ramo. That is right. I would expect it would be more probable, however, that this pure research organization, be it a separate department involving a Cabinet post or not, would recognize that its entire reason for existence was to search into the unknown without concern as to whether there is or is not a military possibility.

Mr. O'Brien. We have had mentioned here a number of peacetime developments which are also tied in with the military. I do not know where I picked this up, but someone stated that if we arrived at the point at which we were aiming it might be possible one day to place a caravan of drone vehicles in the sky over New York City and deliver the cargo 20 minutes later in London.

Am I going too far, or is that feasible within the framework of our present speculations?

Dr. Ramo. That is feasible, from the standpoint of our understanding of physics. More than that it is feasible from the standpoint of engineering, it is just around the corner.

The Chairman. Mr. Natcher.

Mr. Natcher. Dr. Ramo, as I understand your statement, you recognize the importance of the problem before this committee, but you believe we should proceed in a careful and cautious manner recognizing the important problems from a military standpoint and go further; is that correct?

Dr. Ramo. I think that is correct. Your choice of wording suggests to me that I ought to again try to restate what you have said in my own words.

I think in the process of recognizing the need for more space research we should not inadvertently create another type of rivalry—which is the kind of rivalry that the proposed Defense Department reorganization is trying to eliminate—between the Defense Department, engaged for valid reasons in carrying out major space programs, and a new agency, which for equally valid but somewhat different reasons, is carrying out virtually the same programs.

This could happen if we are not careful in the way we set this up.

Mr. NATCHER. Doctor, have you had a chance to examine the bill which is before the committee?

Dr. RAMO. Yes, I have.

Mr. NATCHER. Are you in favor of an agency controlled by a civilian group, that is not military control? How do you feel about that?

Dr. RAMO. I feel that if the agency's prime work is to do pure research without a clear military objective, that it should be controlled by civilians.

Mr. NATCHER. Thank you.

The CHAIRMAN. Are there any further questions?

Mr. Sisk.

Mr. SISK. Doctor, would you recommend the retention of ARPA then, and a liaison between ARPA and the new agency be set up?

Dr. RAMO. I would very definitely recommend the retainment in the Department of Defense of the necessary capability to direct, plan, and execute programs in space.

Mr. SISK. Either ARPA or something similar?

Dr. RAMO. Either ARPA or something similar.

The reason I avoided saying ARPA is that I am aware of the fact that there are recommendations for Defense Department reorganization in which I do not claim expertness.

The CHAIRMAN. Are there any further questions?

Mr. McDonough.

Mr. McDONOUGH. Dr. Ramo, do you see a relationship in a Secretary of Science on the Cabinet level, a relationship with and a cooperation with space and nuclear development?

Mr. RAMO. I think there is a relationship. I cannot claim to have expertness in the sense of how they are related as to common agency and common direction, but I would say that in considering a separate Department of Science, the Atomic Energy Commission, this agency presently being considered for space, the National Science Foundation, and perhaps certain other organizations should be considered as candidates for that department.

Mr. McDONOUGH. That would, of course, make it more civilian than military for the reason that the National Academy of Science and the National Institute of Science and Atomic Energy is devoted principally more to civilian development than it is to military.

Dr. RAMO. Yes, I think that is true. But on the other hand, I emphasize that the functions of that group should be to do pure research as much as possible, as distinct from the clear military developments.

Mr. McDONOUGH. How far should they go in research? Merely be an agency of government to provide difficult things for private industry that private industry could not possibly do on its own, finance on its own?

Dr. RAMO. I think there has to be a combination here. I think it is very difficult to get a black and white rule.

Largely, of course, this agency would take on that class of project which requires such financing and is so speculative that it is unrealistic to expect private industry to take on the job.

For example, I mentioned that there are clear indications that improved worldwide communications for the future would involve satellites. I think that indication has existed for some years and has been a topic of conversation within the electronics industry.

Yet I think it is unrealistic to expect the broadcasting companies to undertake a multibillion dollar job of developing everything from the boosters through to payloads and all of the myriad ground equipment in order to bring about worldwide TV.

So there are some projects that just by their scale and their cost require or appear to me to require a Government sponsorship.

Mr. McDONOUGH. The major things for civilian development would be communications, weather predicting, and transportation?

Dr. RAMO. Yes. In the space field. I think you can count on private industry to go after those things that have not only a near-term, but even a long-term potential.

There is a way of the whole idea paying off with our particular way of life in this country. But if it gets too big, or too long range, or too speculative, then I think we need Government support.

The CHAIRMAN. Are there any further questions on the Republican side?

Mr. Fulton.

Mr. FULTON. How big a budget would you have for the Federal Government to spend annually on basic research for civilian purposes for outer space?

Dr. RAMO. Since you recall that I am making the assumption that there would be very large military programs involving billions of dollars a year, and a great deal of coordination, in that case the pure research, as distinguished from the military, in my opinion is less than the billion-dollar level and is in the hundreds of millions.

I am not able really to say, to tie it down any closer than that. Tens of billions is too large; 100 million is too small, but I think a billion is not required if proper use is made of the military development.

Mr. FULTON. I was just asking to get the general magnitude of your thinking.

As the law stands, in order to leave this country, you have to get a passport. The question then arises, should anyone who is a citizen of the United States be able to go into outer space without hindrance or without Government approval?

Dr. RAMO. The best thing I can do is say that that is a type of question on which I regard myself as quite incompetent.

Mr. FULTON. The question is should any person, group of persons, or business, have the right on their own to go into outer space or put objects into outer space, or should the Government have a law to control the use of outer space for each of our citizens or residents?

Dr. RAMO. There is a partial answer that I think I can give that rests on some technical facts about which I have some competence.

Mr. FULTON. Does freedom of enterprise go into outer space? should we leave it open for business to do it?

Dr. RAMO. Clearly in my opinion we cannot prevent other nations from doing it. What we can prevent is what our own citizens do.

I think it is clear that we could set up laws and enforce them.

Mr. FULTON. Not prevent, it is control. Should there be Government control, or should there be freedom of business enterprise by individuals to do what they want in outer space?

Dr. RAMO. If we put aside the question——

Mr. FULTON. Put a statement in the record. You can think it out.

Dr. RAMO. I might not properly appreciate your question, but there are dangers involved to the civilian population.

Mr. FULTON. All right, should the teen-agers in your neighborhood be able to put a missile into space?

Dr. RAMO. There is no question but what we shall have to have laws to control what our citizens do.

Mr. FULTON. Should the teen-agers in your neighborhood have a right to put a missile into space by their joint action?

Dr. RAMO. Definitely, no.

Mr. FULTON. Should businessmen who decide that they want to do certain things for profit be able to put advertising signs in outer space or over and around us, whether we want them to or not?

Dr. RAMO. I am quite confident we shall have to set up controls for a number of reasons, the most urgent one of which is, of course, safety.

Mr. FULTON. Then you have heard of the electronic and radio system where the beeps are so fast they invade your consciousness without your knowing it and imprint advertising slogans on your brain. Should we permit that?

Dr. RAMO. I would be very much against that, personally.

Mr. FULTON. You would not permit, then, any business promotion in outer space; is that right, in your business?

Dr. RAMO. I think that what I would permit is application to the Government and some type of Government control.

In other words, a technique of licensing. Perhaps that is a way of saying it.

I would not assume at the outset in considering this question that private business should be kept by law from putting private articles into outer space, but I think it should be under Government control that they do it.

Mr. FULTON. I was inquiring to see whether there was a ceiling or route on free enterprise in this country or whether is goes up as high as property ownership does.

According to you, it does not.

Dr. RAMO. I do not know of any altitude ceiling that I can think of as a basis for establishing control. I think control is one thing, but an absolute ceiling is another.

Mr. FULTON. But where should the control begin? At what level should the business begin to come under government control?

Dr. RAMO. It may be a question of extending the rules that we already have for aircraft.

Mr. FULTON. Thank you very much.

That is all, Mr. Chairman.

The CHAIRMAN. Are there any further questions?

Mr. Metcalf, I overlooked you. Did you want to ask some questions?

Mr. METCALF. I was not overlooked, Mr. Chairman. I do have a question, if I may.

Your question was "Can NACA be the proper vehicle," and you said it would be a complete vehicle. Does that shut out some of the other means of taking care of civilian organizations such as the commission and these things discussed today?

Dr. RAMO. When I asked that question myself and answered it, I was recognizing that there was already a discussion of the NACA's being converted and enhanced to become the new agency.

I thought it might be well to put in a comment as to the dealings which some of us have had with NACA over the years. It has impressed us as having done such a job both as to quality and as to the nature of its duties that it was suitable. I was merely saying that it seemed to be a logical candidate.

No, I do not rule out other ways of arranging for the new space agency.

The CHAIRMAN. Mr. Feldman?

Mr. FELDMAN. What direct military value do you see now in putting a man on the moon?

Dr. RAMO. I am afraid this has to be a long story.

Mr. FELDMAN. Can you make it brief?

Dr. RAMO. I can see no direct military value in putting a man on the moon today except as an indirect way of arriving in the most effective way possible at the capability of putting a man where we want to put him in outer space.

Since in complex military weapons systems in the future one of our races with Russia is the ability to design what we need to design in the way of a combination of men and machines, we would not want to be in the position of having an inhibition or rule which said one component, man's brain (which is the equivalent of 10 billion electron tubes) cannot be put in certain parts of the system in which we wish to work while the Russians can put man wherever they choose.

Our inventors of military weapons systems would then be handicapped as compared with theirs. But to put a man on the moon for a very specific purpose, such as, for example, to drop bombs on us, that, to me, is not a valid reason as of today.

Mr. FELDMAN. What is the most ambitious project which can be done with the ICBM booster rockets?

Dr. RAMO. I can give you examples. With a natural extension—which means to replace the payload, the warhead, on top with straightforwardly designed other apparatus—we could put instrumentation around Mars so as to make some preliminary investigations of Mars close up. That is an example of an ambitious, fairly spectacular achievement and one extremely interesting to science.

Mr. FELDMAN. Do you see any direct military value to a million-pound-thrust rocket?

Dr. RAMO. In connection with putting man up where we want to put him in space, in accordance with my previous comments.

The CHAIRMAN. Thank you very much, Doctor, for appearing and giving us the benefit of your knowledge.

Will you put Mr. Donovan's full name in the record, too, please?

Mr. Donovan, have you any observations?

STATEMENT OF ALLEN F. DONOVAN,[14] VICE PRESIDENT AND DIRECTOR, AERONAUTICS LABORATORY, SPACE TECHNOLOGY LABORATORIES, A DIVISION OF THE RAMO-WOOLDRIDGE CORP., LOS ANGELES, CALIF.

Mr. DONOVAN. I am Allen F. Donovan. I am the vice president and director of the aeronautics laboratory, of Space Technology Laboratories.

The CHAIRMAN. Do you have any observations you want to make?

Mr. DONOVAN. I think Dr. Ramo has covered most of the points that I would. I might perhaps enlarge on a few items which I think would be of interest to the committee, particularly those related to the problems of getting into space.

I would like to point out that we are about to have, really already have in operation the first spacecraft. By spacecraft I mean machines capable of leaving the earth, going into space, and landing either back on earth, or on some other body in space.

Mr. KEATING. Manned or unmanned?

Mr. DONOVAN. Either one. If it were a spaceship it might imply manned. Spacecraft, as I use it, might mean manned or unmanned vehicles.

The CHAIRMAN. Can that be regulated from the earth?

Mr. DONOVAN. It could be either regulated from the earth, or controlled in certain cases by men on board.

Mr. McDONOUGH. You say this is the first. Do you mean this is a reality now?

Mr. DONOVAN. I mean we are about to get intercontinental ballistic missiles (ICBM's) which have a flight time of 30 minutes, of which 25 minutes is in space, hence they are really spacecraft. We already have intermediate range ballistic missiles (IRBM's) which spend over 10 minutes in space.

At the speeds they reach they are at almost 90 percent of the speed required to go into orbit or to satellite. When you extrapolate what can be done with a vehicle which is already up to 90 percent of the speed required to get into orbit, you find its capabilities are quite remarkable. The ICBM's reach two-thirds of the speed needed to escape from the earth's gravitational field and go to the moon or, alternatively, to travel to the planets Mars or Venus. The speed achieved, I would like to point out, is approximately 16,000 miles per hour, or nearly 10 times the speed record of the X–2 airplane.

We are making a tremendous advance in our ability to reach high speeds. To give you an idea of what this means, I think we can point out the very remarkable achievement of the Army in using the

Redstone, a missile which was capable of reaching only a little over a quarter of the speed to get into orbit, or about 5,000 miles per hour. Yet, by putting smaller stages on top of it, they were able to push a small payload up to satellite speed of 18,000 miles per hour. If we increase ICBM speeds by the same percentage, we have more than enough velocity to go to Mars and back.

Therefore, with an ICBM which is capable of getting almost to the speed needed to orbit by itself, we can do many space missions by putting additional stages on top of it. It can be used very effectively for both military and civilian space objectives.

I will point out that on any particular flight of these spacecraft it is going to be difficult to determine which objectives it is being used for. Some objectives will have military applications; some will have civilian applications. It might in one particular flight be 60 percent military, 40 percent civilian. It makes no difference which it is as far as the spacecraft is concerned. It is the same basic machine.

The same is true of aircraft. The design for General LeMay's tankers is now being converted into the Boeing jet airliner.

Therefore again in space you need only one basic set of spacecraft in order to accomplish both military and civilian space missions.

Now, if we take the ICBM's or the IRBM's and add to them the 10 to 30 percent of additional pieces that would make up the upper stages, it will be found that we can make some very remarkable space trips. Some of these possibilities have already been reported to Congress. For example, a man could be put into orbit and brought back to earth, and an ICBM with upper stages could accomplish a manned trip around the moon and back to earth. Sizeable payloads could be landed on Mars and Venus and this can be done at a modest cost relative to that for the basic ballistic missiles program, because the big part of the total spacecraft, the ICBM, is already in flight test.

To give an analogy, we are a little bit like the farmer who has bought a tractor in order to haul explosives, but has neglected, however, to buy a plow, a mowing machine, a hayloader, or any of the other cheaper attachments that will really make his tractor effective.

The analogue is not perfect in that the ICBM pushes, whereas the tractor pulls. However, the ICBM is a large basic power unit that can get sizeable upper stages and payloads up out of the basic atmosphere and up nearly to the velocity where they become satellites.

On top of the ICBM's, then you put the other stages which enable you to gain additional velocity. With these smaller upper stages you use higher energy propellents, which you can afford to use in these smaller units, and thereby gain very high velocities.

Once you do these things, you open the way to very remarkable possibilities. For example, you can put telescopes into space, where they would not be hindered by trying to see through the earth's dense atmosphere. One expert in spectographic studies of the sun has told me that such space spectographs might permit learning about suspected heavy element thermonuclear reactions in the sun, and that this knowledge could result in remarkable advances in both the military and civilian uses of thermonuclear power.

Mr. McDonough. Would he not run into the problem of getting into such enormous heat that the whole thing would burn up?

Mr. Donovan. No, we think we know how to solve all such problems, how to put the vehicle out into space and bring the crew back safely, and how to do it in a manner such that if thrust is lost any-

where from the initial takeoff to burnout of the final stage, the crew can return safely to earth. That is, the crew can escape at any point in the flight starting from the launch time.

Even at the time of launching, the crew would have an ejection mechanism so that if the booster rocket fails in the launching, they could catapult themselves up and parachute down safely.

Mr. McDONOUGH. What you have just said is that the initial unit, the initial thrust power unit, is the big problem.

Mr. DONOVAN. This is true. The ICBM is such a unit and costs the big money. You have already appropriated it and we at the Ramo-Wooldridge Space Technology Laboratories are assisting the Air Force in seeing that the money is spent to develop ICBM's as rapidly and efficiently as possible.

Mr. McDONOUGH. That is the biggest problem, that once you have the big power unit that can get away from the drag of the atmosphere and the terrestrial gravity of the earth, from there on it is not so much of a problem.

Mr. DONOVAN. It is much easier from there on. It does not take nearly as extensive developments to provide upper stages for many significant objectives.

Now, it gets harder if you want to put a man on the moon and bring him back. For that we need more thrust than we will have in the ICBM's. Also, I believe we will need more thrust for military purposes. I cannot outline these purposes clearly, but I can say that there is certainly at least as much justification now for a million or two million pound thrust rocket engine for military spacecraft as there was, say, in 1952, before the thermonuclear breakthrough, for engines the size being used in ICBM's.

Mr. McDONOUGH. Let me follow you from this point. You have this large power unit for the initial thrust and you have used 2 or 3 stages of additional thrust beyond that.

You have the man into space and you want to transmit him from that point, the highest point you have shot him at the third stage, to a planet, we will say, what power unit do you have on the satellite to transmit him there and bring him back?

Mr. DONOVAN. We cannot with the ICBM's take a man to another planet and bring him back. We can take significant payloads which will be able to radio back important information. We cannot take a man to another planet or even to the moon and back without another step upward in thrust.

We can take a man around the moon and bring him back into the earth's atmosphere, I believe, and land him safely, enabling him to see the back side of the moon. That is considerably easier. It is no harder to go around the moon than it is to hit it from the propulsion standpoint.

It is a little harder from the guidance and steering standpoint.

Mr. McDONOUGH. You have the difference from the last thrust of the rocket, you have the satellite then, we will say, at 50,000 miles away from the earth. You still have 200,000 miles to go to get into the orbit of the moon.

Dr. RAMO. But he is coasting.

Mr. McDONOUGH. You coast?

Mr. DONOVAN. You accelerate very quickly to the speed required to go to the moon. You reach this speed at an altitude of only about 500

miles. You then coast. You coast for 2 days, and during this period you slow down.

The moon is up here. After 2 days you get to the point of balance between the gravitational pull of the moon and the earth. At that time you would have slowed down to where you would be going only about 500 miles an hour.

Mr. McDONOUGH. Now you are coming into the gravity of the moon?

Mr. DONOVAN. Then, if you are going to go around the moon, you speed up as you go towards the moon, you pass the moon going maybe 2,000 miles an hour at a reasonable distance. The gravitational pull pulls you around the moon, curves you back towards earth, and you come back tangentially into the earth's atmosphere, decelerating in it, slowing down and finally landing safely on the surface of the earth. While I can say here that these things can be done, I would have to give you the details in closed session.

Mr. KEATING. I would like to hear him in closed session.

Mr. McDONOUGH. Now this is not just Buck Rogers, this is reality.

Mr. DONOVAN. This has been presented to Dr. Killian, Secretary Douglas, General White, and numerous people throughout the Air Force.

Mr. KEATING. What temperature are you going to run into within 2,000 miles of the moon, 200 degrees below zero?

Mr. DONOVAN. Your temperatures will be about the same as in the satellites circling the earth, which are quite moderate.

Mr. KEATING. What is the outside temperature in the satellites circling the earth?

Mr. DONOVAN. The inside one they are holding around 70 degrees. The outside temperature is not going up very much.

Mr. KEATING. But it is pretty low?

Mr. DONOVAN. No, because the sun hits it and keeps it warm on one side.

Mr. KEATING. I thought I read where it was down to 100 degrees below zero.

Mr. DONOVAN. The tendency is to go down on the side away from the sun and up on the other side. By properly arranging your surfaces and providing internal circulation you can maintain the temperature you desire.

Mr. KEATING. Dr. von Braun when he was here in the opening of the committee said that within a year he could send a man into a satellite within 150 or 200 miles into the atmosphere. You are saying that he can go beyond that and circle the moon and come back.

Mr. DONOVAN. I think Dr. von Braun said he could send a man 150 to 200 miles straight up within a year, as I remember, and bring him back down. Dr. von Braun has usually been quite able to carry out the experiments that he has said he could do, so I believe he probably could do this one. I think the question is whether the value of the information so obtained is worth risking a man's life.

Mr. KEATING. What about the effect of the intense gravitational pull on the man in such a satellite or capsule? How many gravities would he have to sustain in going up?

Mr. DONOVAN. Again I would have to give that in closed session.

The CHAIRMAN. Are there any further questions?

Mr. O'BRIEN. May I ask one question, Mr. Chairman?

The CHAIRMAN. Certainly.

Mr. O'BRIEN. Mr. Donovan, I know it is a fact that you are highly regarded in scientific circles. Do you believe that our educational system as now constituted is capable of producing scientific knowledge that we require?

Mr. DONOVAN. I am concerned that our educational system as it has been operated is not putting sufficient emphasis on science, nor enough on discipline and on taking advantage of the capabilities of the exceptional student. I see some rather strong trends toward improvement recently.

The CHAIRMAN. Any further questions?

Mr. FULTON. Mr. Chairman, I have one question.

A question comes up when you have inferentially said that the propellents now used for an instrument like the Vanguard are buried in stages because of the cost, so if you start on the first level with oxidation type propellents and the second type with hypergolic type propellent and the third stage with smaller solid propellents, pressurized, suppose you started the first stage regardless of cost with the third stage fuel, how small an instrument or vehicle would you then have?

It seemed to me when I was at Cape Canaveral there was such an elephant body and such a small rabbit head for the orbiting satellite. How small a vehicle would you get so that you would not have to have one 60 feet high with a structure like a stone wall?

Mr. DONOVAN. Again, as to the possibilities of size reduction, I would have to go into classified information.

Mr. FULTON. Could you use the third stage without first or second stages, if you put enough power in the one?

Mr. DONOVAN. I think it is obvious if you put enough power in. Whether you could get enough with particular sizes and propellents is more questionable.

Mr. FULTON. That is all.

The CHAIRMAN. Thank you very much, Mr. Donovan, and also again to you, Dr. Ramo.

By the way, you can edit your remarks. I hope you will elaborate and express any other views you might have overlooked or clarify any views you have expressed.

Dr. RAMO. Thank you, Mr. Chairman.

The CHAIRMAN. The next witness is Dr. Arthur Kantrowitz, director, Avco Research Laboratory, Everett, Mass.

Doctor, you have been patient. We appreciate it very, very much. We shall be very glad to hear from you.

STATEMENT OF DR. ARTHUR KANTROWITZ,[15] DIRECTOR, AVCO RESEARCH LABORATORY, EVERETT, MASS.

Dr. KANTROWITZ. Thank you, Mr. Chairman.

I would like to begin by giving my prepared statement and some ideas that I would like to bring before you in connection with the

[15] Kantrowitz, Arthur, physicist, b. N. Y. C., Oct. 20, 1913; s. Bernard A. and Rose (Esserman) K.; B. S. Columbia, 1934, M. A. 1936, Ph. D., 1947; m. space program. I want to say at the outset that I am no expert in the administration of these large scale programs, so I do not pretend to give you any detailed suggestion but I just want to call one item to your attention.

Mr. McDonough. Feel right at ease. We are not experts either.

Dr. Kantrowitz. Thank you.

ADMINISTRATIVE ORGANIZATION FOR SPACE FLIGHT

In order to keep up with or to surpass the Russians we must build a spirit of adventure into our administration of the space program. In other words, our administrative system must make it possible for our native spirit of adventure to express itself.

The closest analogy to what we have to do is to be found in the inventive process—as it has operated in the past. What I would like to outline is the way great progressive inventions have been made, and to see if something like this couldn't be set up in the space business. Individual initiatives has worked beautifully where only small resources were required to make a daring experiment or an important invention. In the past great experiments and inventions—those that have profoundly changed our thinking and our lives—could be done by people who had the courage to risk their time and effort on ideas which were not yet generally accepted.

A good example and one close to our present problem is furnished by the enthusiasts who pioneered in aviation. The general scientific opinion at the time was that manned flight was not yet possible. This was illustrated by an article written by the distinguished American astronomer Simon Newcomb who, as late as 1906, wrote an article proving that manned flight was not feasible by the application of scientific principles known at that time. Fortunately, however, this opinion did not stop the enthusiasts from trying out their ideas.

Consider, however, the situation regarding manned space flight. The cost of a manned satellite program will be a substantial fraction of $100 million. It is clear that this pioneering experiment must be Government supported. Consider now the conflict between the traditional operation of our Government by majority rule and the necessity for allowing our enthusiasts the opportunity to advance faster than the general opinion of scientists think possible.

Consider also the tremendous difficulty which faces our Government in distinguishing between the rare enthusiast who is capable of great progress and the technically irresponsible who do their best to imitate these invaluable people. I should like to propose the following philosophy—that the delegation of authority to lead large-scale experiments be made in a manner analogous to the technique employed in the organization of an adventurous business enterprise. That the substitute for capital, in this case, should be the reputation of scientists who are willing to devote themselves to the project in question. In this way, we can achieve the closest identity between authority and responsibility.

Consider, on the other hand, the way that our current administrative decisions concerning great projects are made by scientific advisory committees made up of distinguished scientists. The membership of these committees cannot, remembering their judicial role, emphasize individuals who have an enthusiasm for the project in question. They, therefore, in their objectivity, record merely the general climate of

thinking at the moment and tend to recommend the adoption of unadventurous policies.

The plan I would propose would restrict the activities of such scientific committees to the evaluation of the reputation of those scientists and engineers who are willing and anxious to devote themselves and to pledge their reputations to the achievement of special projects. These scientific committees would thus serve essentially to establish the "credit rating" of the backers of a project. Note that these backers must be willing to commit their time and reputation to the success of a project, and not just offer their judgment that it is a good or bad idea.

I submit that this type of procedure would give us a far closer coincidence of responsibility and authority than we now have. The formulation of a bold administrative policy in areas of adventurous and expensive research will buy us the speed which is desperately necessary for survival in our time.

I want to depart from my written statement to tell you briefly about an experience of my own in this regard.

Three years ago when the reentry problem first became prominent, it was thought that there were no methods of duplicating in the laboratory the conditions that would be faced by an ICBM during reentry. I had been doing some basic research which involved the creation of just such conditions in the laboratory. It was, however, considered that the instrument which I used, the shock tube, was not yet ready for application to provide the data needed by the ICBM. However, it was possible to convince the ballistic missile division of the Air Force and the Ramo-Wooldridge Corp. that they should take a chance on the possibility that we could do this in the laboratory. They took such a chance and it worked.

I have made the previous statement in the hope that the opportunity for people to do things which are beyond what a judicial committee could guarantee are feasible, that this opportunity must somehow be incorporated into your thinking on this new bill.

MANNED SPACE FLIGHT

What has to be done before we can achieve manned space flight? The first problem is the launching. The launching of a vehicle large enough to carry a man obviously requires very powerful rockets and requires that these rockets be well guided. Thus, our ability to launch a manned satellite into orbit is closely related to our ICBM capabilities. We have been and will continue to devote great effort to achieving ICBM capabilities soon. The country is thus heavily committed to the development of large, reliable rockets with accurate guidance systems. Dr. Ramo can inform the Congress on our success to date in this vital development. It will therefore be interesting to delineate the other problems which must be solved before manned space flight can be achieved.

The first group of problems are the physiological ones which have been under investigation by the Air Force and Navy aero-medical services. There are the accelerations which man must experience in launching which may be as much as 10 times gravity (10 g's). There is a good deal of experience to indicate that a man suitably positioned can take this. When he is out in space he will be weightless. This condition is one which unfortunately cannot be duplicated on earth

for more than a short time. Authorities on this subject, however, do not believe that this will be an insurmountable problem.

There are unusual radiations to be met in space (primary cosmic rays, solar X-rays, etc.) from which we are ordinarily protected by our atmosphere. The evidence is, however, that a very thin metal skin will protect a man against these radiations other than cosmic rays. The consensus of professional opinion is that cosmic radiation hazard will probably not be a severe risk for space flights of a few days.

The problems connected with food, water, oxygen supply, and waste disposal do not seem particularly difficult. There is weight allowance required of the order of 10 pounds a day for supporting a man in these 3 requirements. Lightweight and simple air conditioning and communications equipment, power supply, and other necessities are within the present art. Thus the sustenance of a man in flights of a few days' duration would not involve any great supply weights.

Next, there is the well-known possibility of meteoritic impact, and there seems to be a considerable likelihood that impacts by microscopic meteorites will have to be expected. Protection against these can again be achieved with a thin outer skin. It is known that impact with large meteorites is a rare phenomenon. This is a risk which will have to be taken; however, it will probably not be greater than that involved in driving home from the landing point.

I should like to say that none of these problems seem at the present moment to interfere in any serious way with the capabilities of space flight. There is the problem of weightlessness, which is somewhat unknown at the moment, but the best medical authority seems to be that this also will not interfere with space flight.

Granting then that we have the ICBM as a working and reliable device——

Mr. McDONOUGH. Before you get off weightlessness, have we had any experiments with a human being in a weightless condition?

Dr. KANTROWITZ. Not for any great length of time, only for periods of a minute or 90 seconds.

Mr. McDONOUGH. Why have you not conducted it for a longer period?

Dr. KANTROWITZ. Because we don't know how to do that very easily.

Mr. McDONOUGH. In weightlessness is it not a mental problem and a physical problem? Have there been any experiments to prove what effect it has on a man mentally?

Dr. KANTROWITZ. Not that I know about except for these very short time experiments lasting only, as I say, something of the order of 30 to 40 seconds.

Mr. McDONOUGH. Maybe the information is classified?

Dr. KANTROWITZ. No. But the advice that I have received from the space medical people give me the impression that they are not seriously worried about this problem and that it should not impede our efforts to go out and do this job.

The problem of decelerating a man out of a satellite orbit and returning him safely to earth is probably the most difficult part of manned space flight apart from those elements related directly to the ICBM program (launching and guidance). The difficulty of this problem can be illustrated by considering the tremendous kinetic energy of a satellite. If this energy were transformed into heat, the heat gener-

ated would be many times that necessary to vaporize a satellite made of any known material—if all the heat flowed into the satellite. It is, however, well known that some meteorites do decelerate and reach the earth's surface. During the reentry process some of their outer skin is lost through evaporation and erosion.

A great deal of study of this problem, well known as the reentry problem, has recently been made in connection with the ICBM program. In particular, at the Avco Research Laboratory (working under Air Force sponsorship) techniques have been developed for the reproduction and study of flow about objects reentering the atmosphere at up to satellite speeds.

We have made measurements of the heat transfer, of the radiation that would be produced by the hot air, of the electrical properties of the air, and of many other physical phenomena that will accompany reentry.

As the satellite heats it also begins to decelerate rapidly so that at peak heating it is decelerating at about 4 g's. After peak heating, deceleration continues to build up even though the exterior skin of the satellite and its parachute are already cooling, and it eventually reaches a deceleration of nine times gravity. This deceleration is again within the tolerance limits of men properly supported in a nearly prone position. After peak deceleration, the satellite will gradually slow up to a very low speed and the parachute will return it gently to earth. The falling phase will take about one-half hour. The satellite will strike the earth with an impact comparable to that experienced by objects dropped in a cargo parachute.

HISTORY OF AVCO WORK ON MANNED SATELLITE DESIGN CONCEPTS

About 2 years ago we at Avco Research Laboratory recognized that within the next few years two major barriers to the accomplishment of manned space flight would be removed. These previous barriers were:

1. The lack of a large rocket-propelled launching vehicle capable of lifting a few thousand pounds into an earth satellite orbit.
2. A lack of precise understanding of the fundamental problem of reentry heating of satellite vehicles. This knowledge has been obtained as a logical extension of research following IRBM and ICBM reentry studies.

Furthermore, the development of the ICBM was recognized to represent a tremendous investment of this country's resources. Accordingly, we believed that the ICBM should be exploited to the fullest extent to obtain the maximum value from the millions of dollars invested in its development.

Following discussions with ARDC, a study was directed toward the launching of manned vehicles and culminated in a proposal which was submitted to ARDC headquarters on November 21, 1956, for a "Manned Ballistic Rocket System Study." This proposal was coordinated within the ARDC structure, given technical approval, and assigned a high priority in the spring of 1957. Although no contract was awarded for this work because of lack of funds, study was continued with Avco funds. The results of this study indicated that a manned satellite system based on ICBM launchers was feasible. To reflect this advance in thinking, a "Minimum Manned Satellite" proposal was submitted on November 20, 1957.

MAJOR OBJECTIVES OF THE MINIMUM MANNED SATELLITE (MMS)

The primary objectives of the MMS were as follows:

1. To establish in minimum time a manned orbital flight capability with controlled reentry to a selected landing location.
2. To determine the problems of maintaining a man in space with an approximation to his terrestrial capabilities.
3. To establish the capability of placing a manned vehicle into orbit from which he can either land safely on earth or move out to a permanent orbit by use of practicable space propulsion devices. This orbit we refer to as the "orbit of decision." Achievement of this objective would be the major breakthrough in establishing manned space flight as a reality.
4. To demonstrate the advantages of a drag vehicle for accomplishing a safe, controlled, manned reentry from a satellite orbit.

EVOLUTION OF DESIGN OF MMS

In the course of the above study many different types of rocket-launched manned vehicle systems have been explored. Initially it was thought that a gradual approach to orbital flight would be most effective. This is analogous to the X–15 approach that Dr. Dryden explained to you. In this concept a manned vehicle would be launched to gradually increased velocities and altitudes until finally true satellite flight is obtained. It became apparent, however, as the study progressed, that the reentry of a manned vehicle is most easily accomplished from orbital flight. For accomplishing this reentry, both winged and unwinged vehicles with variable lift and variable drag were considered. While some of these ideas showed merit in specific problem areas, we were led to the logical conclusion that a pure drag reentry vehicle was greatly superior in satisfying the overall system requirements.

HOW SOON CAN THE MINIMUM MANNED SATELLITE BE REALIZED?

More than a year ago it was recognized that the earliest date on which a manned satellite vehicle could be realized was to be governed not by the time for development of the satellite itself. Rather, the earliest date would be determined by that on which a safe and operationally reliable launching vehicle would be available. To achieve this reliability, a certain minimum number of successful firings of an ICBM are required.

Because of the overriding importance of the reliability factor in any American manned space flight, we turned quite naturally to the ICBM which had been tested most, the Convair Atlas. Accordingly, we discussed the matter with the Convair Astronautics Division of the General Dynamics Corp. As a result, an agreement was reached whereby a joint corporate proposal would be made to the appropriate authorities. We are firmly convinced that this Avco-Convair team can produce the earliest realization of manned space flight. This proposal is to be presented to ARPA on the 2d of May.

CONCLUSION

In conclusion, it appears that at the present time no great scientific discoveries are needed to achieve manned space flight. It thus becomes a matter for decision. Is America willing to pay for it?

It is not yet clear how or whether manned space flight will be important in a military sense. Historical perspective, however, may be useful to supplement the deficiencies in our imagination. Some of the revolutionary weapons of this century were the airplane, radar, and nuclear energy. In all of these cases the initial developments were undertaken with nonmilitary objectives in mind. The airplane was once just a challenge similar to that of the present-day potential of space flight. Radar was once just a powerful way of studying the ionosphere. As for nuclear energy, the original applications were not to bombs but to the generation of power.

It is my opinion that America cannot afford the gamble that this pattern will not be repeated in space flight.

Mr. O'Brien. Thank you very much, Dr. Kantrowitz.

I was interested in the reference to adventure. I think to a certain extent we might use the word "gamble." Gambling with ideas. Would it be your thought that there would either be a separate agency or an agency within the proposed agency that would deal specifically with the personality of scientists, plus the probability of success in the particular project we are interested in; in other words, not tie it down to an immediate military objective or an immediate appropriation that might or might not be approved by Congress? Is that the idea? You want a field in which the scientists with an idea, who is willing to risk his time and reputation, can operate?

Dr. Kantrowitz. That is right; whether his objectives have been purely scientific or militarily important. The point I was registering a sort of inarticulate objection to is the kind of committee system under which we operate which prevents the person who has ideas which are not yet popular from getting the kind of support that he could have when he can just operate on his own funds, as the Wright brothers did, for example. This is a very difficult thing to do nowadays.

Mr. O'Brien. In other words, he could go so far without investment of tremendous sums.

Dr. Kantrowitz. In many cases he could.

Mr. O'Brien. Then he would arrive at a point where huge sums are necessary. When you get to the tens of millions, then this agency could exercise this judicious function.

Dr. Kantrowitz. I think they should depend greatly on the reputation of the individuals who are willing to risk their reputation and their time in the execution of a project rather than depending heavily on the advice of people who will not be involved with the project personally, whether it is accepted or not.

This judicial function I think tends to maintain tradition at the expense of the adventurous approach.

Mr. O'Brien. The exercise of the judicial function around 1492 would not have resulted in the competition by Columbus.

Dr. Kantrowitz. I would think so. The climate of opinion I think was against it at the time.

Mr. O'BRIEN. I know that you and several others speak very confidently of this manned space travel and going to the moon. Actually, scientifically you are more certain that man in a vehicle will go to the moon, go into space, than the scientists just a few hundred years ago were that the world was round; is that right?

Dr. KANTROWITZ. I think so. You will find statements in the press, perhaps some before your committee, that people have the impression that manned orbit flight is a long way off. With this I disagree. It can be a long way off for this country. Whether it is a long way off for the Russians, I don't know. I think we can do it quickly if the authority is forthcoming.

Mr. O'BRIEN. I have one final question:

In this suggestion of yours that scientists be given an opportunity for Government help if they are willing to risk their reputation, would that not be a quick way of achieving this leapfrog idea that we all have in mind?

In other words, I think a great many of us are tired of playing tag with the Russians; we would like to jump ahead of them.

Dr. KANTROWITZ. That is right. We will take a chance, we will make mistakes this way, but it won't be as humiliating as being behind the Russians.

Mr. O'BRIEN. We still have some people in the country that figure we have three up now, the Russians have none, we are leading the ballgame 3 to 0, so it is time to buy another bag of peanuts and watch the game.

Are there any of my remaining Democratic colleagues that have any questions?

Mr. SISK. Mr. Chairman, I would simply like to ask the doctor in the extension of his remarks in the record to make a statement with reference to whether or not you feel that the proposed legislation which this committee has before it is a proper vehicle or provides the proper method for expediting and giving to you and to other scientists and engineering people the weapon to proceed to do this job as quickly as possible? I am not going to ask you to comment at the present time, Doctor; I realize it is quite late. But in the extension of your remarks which you will be given the privilege of doing, discuss the legislation. I am sure you have read the bill.

Dr. KANTROWIZ. I have read it, but I do not consider myself competent to say whether that bill will provide what I am asking for.

Mr. SISK. I would appreciate your criticism, but if you prefer not to, I will withdraw my request.

Dr. KANTROWITZ. Thank you, sir.

Mr. SISK. Thank you, Mr. Chairman.

Mr. O'BRIEN. Mr. McDonough.

Mr. McDONOUGH. Dr. Kantrowitz, I appreciate your statement. You have a very, very vivid practical view of the future on this spaceflight business. Coming from one who has experimented and speaks with some authority on the subject, it is very refreshing to know. In other words, we can do this if we get to work and get at it.

Dr. KANTROWITZ. That is it.

Mr. McDONOUGH. And speaking of the potential educational facilities that we have in this country and the present inventory of scientific manpower and brains, how in your opinion do we stack up against the rest of the world?

Dr. KANTROWITZ. I have for some time been very much worried about the tremendous Russian emphasis on scientific and engineering education. I feel, however, that our educational system is a reflection of the general climate of thinking in this country, that this has been improving fundamentally, that we have been humiliated once with the sputnik. We are moving in the direction of appreciating these things more at the grassroots level, and this will be reflected in time in the areas that are important.

I fear, however, that the many years' lead that the Russians have on us in this educational race will not be made up, that we will be faced in the future with many humiliations of the sort what we have had in the sputnik business.

Mr. McDONOUGH. Outside of the space technology, in what other scientific fields are they advancing faster than we are?

Dr. KANTROWITZ. I do not think that there are many areas where they are currently advancing faster than we are. The thing that alarms me is that they are educating larger numbers of people.

Mr. McDONOUGH. Under rigid discipline.

Dr. KANTROWITZ. Under rigid discipline, but so far as I can tell in the last few years, at least, the rigid discipline does not prevent freedom of scientific thought. There was a period when it did, the Lysenko kind of regime there, but so far as I can tell, that is not any longer the case. Their repression of civil liberties in other areas does not extend to an interference with the freedom of scientists to do purely scientific work.

Mr. McDONOUGH. It is my opinion that on the broad front, taking the broad scope of scientific and intellectual advancement of mankind, that we are way ahead of the Russian people and I think we have much evidence to prove it by our industrial know-how, our production, but I do believe that we have become a little too intoxicated with our own abilities and have not become conscious of the need to continue these things and that there is too little attention given to the requirements of basic studies in the lower grades of school to encourage young people not to be so engrossed with rock and roll but be a little more interested in good literature and good music, and things of that sort.

Dr. KANTROWITZ. I would say it in this fashion: For many years this country was unquestionably the leader in mass education; in the education of large numbers of our people we far excelled what was done any place else in the world. This, unfortunately, is no longer true. Our past efforts in this regard, however, have given us a tremendous backlog of know-how of people were educated 10 or 20 years ago. But at the present time our rate of production of new scientists and engineers is certainly lower than the Russians, so that we are living in the meantime on our backlog of educated people, which is comparable to that of the Russians or maybe a little larger.

Mr. McDONOUGH. The world was pretty much impressed by the shooting of Sputnik I and II into orbit, and because of that they appropriate to themselves all other scientific advances that they probably don't have and have not proved that they have.

Dr. KANTROWITZ. Of course, but there is real danger for the future in such great contests as the contest to make a controlled thermonuclear reactor, which in my opinion is at least as important as space.

These contests we don't dare to lose. They are too important. Space and the thermonuclear reactor are vital.

Mr. O'BRIEN. A great many people are concerned with the possibility that in attempting to catch up with the Russians in science education that we will go too far and strain out the humanities entirely. Don't you feel that it is possible with a little reorganization of our school system to retain the humanities and still produce more scientists?

The reason I say that is that I have observed some of you people who appear before this committee and I have yet to find a mad scientist before us. I have found that nearly every one was articulate in other fields, indicating a background which was not confined purely to science. I do not think in this country we want to turn out a lot of people who are scientists and nothing else but little monsters.

Dr. KANTROWITZ. I would like to submit this notion regarding science and the humanities. It is my opinion that in our times the great creative medium, the great art form of our times is science and technology. The humanists in the universities more frequently are concentrating on the past and not the present as compared with the scientists who are so closely a part of our society today. I think just as music captured the imagination of Vienna in the 19th century, in the same way science and technology are the important kind of creative activity which mean something to the people nowadays.

Mr. O'BRIEN. In one respect do you not think that the spectacular part of all this business we are discussing now is going to have an impact on our education, it is going to create the desire on the part of the youngster to get in that field?

He might be shooting off these rockets that Mr. Fulton is worried about, but he is interested. I think you are going to have the youngsters clamoring for the opportunity, and they might bend this educational system a little bit with help from their parents.

Dr. KANTROWITZ. I was a professor at Cornell University for 10 years, and it has been my experience that the influence of the students on the educational structure of the university was a most beneficial one. Their guidance, the way that they were able to choose professors and to affect the curriculum, showed that they were in many cases wiser than the faculty. It seems to me that this is a very hopeful thing.

Mr. O'BRIEN. I think that Mr. McDonough put his finger squarely on the point. I think most of the responsibility in our failure to keep up with the Russians lies in the arrogance of our generation. I can remember not too long ago, when we were ahead with the atomic bomb, hearing a person whom I respect say, "The Russians are such a backward people; give them the bomb and they will probably blow themselves up."

Then we kept drawing over ourselves a very fine blanket, "Oh, when these German secientists which they captured die, they won't have anything left."

We have seen that exploded in the testimony here. That is a terrible fallacy.

Dr. KANTROWITZ. Yes; but it was widespread just as right now a lot of people think that because we have satellites up there now, it is time for the seventh-inning stretch. I think the youngsters might change that.

Mr. FULTON. Do you not think it is a good thing that Russia is educating her young people, because I understand now because of objections of the students in the Russian's higher institutions of learning, as well as the middle ones, that the komsomol, the Communist youth organization, is not allowed in the schools any more, nor are the Communist political officers permitted in the classrooms or laboratories.

Dr. KANTROWITZ. That sounds like wonderful news.

Mr. FULTON. When you realize that they are educating a whole new generation of educated people, that are raised within a spirit of inquiry rather than rigid polemics, and also raised under a free enterprise system, that if you do well you are encouraged and paid better, maybe they are raising a generation that we can live with.

Dr. KANTROWITZ. That sounds wonderful, Mr. Fulton. I would think it a great thing if we could gain enough confidence in that so that we would not have to worry so desperately as we now do with our military posture. I think too until we gain confidence that we can live with the new generation of Russians that our military posture is absolutely essential.

Mr. FULTON. I am certainly for a good strong military posture now, but I am looking for the future. I just did not want to hear bad comments about a nation educating its young people in a spirit of free enterprise. I think that is rather good.

Dr. KANTROWITZ. It is good in the long view, perhaps, but in the short view it is dangerous.

Mr. FULTON. Have you heard the comment that they have made a survey—we can't tell how accurate—of the Russian college and postgraduate level of students, and have found that there are fewer Communists on the average in the Russian schools than there are on the average in France and Italy combined, in the same age levels?

Mr. O'BRIEN. Would you not say that there are more people in the Russian schools that thoroughly believe it is necessary to destroy us in order to accomplish their objective, whether they are called Communists or not?

Mr. FULTON. Do not misunderstand me. I believe we in the United States need a firm military posture and I voted that way right straight through and voted for defense last year as a Republican, which made me look as if I was not for economy. But we must keep our minds open so that once the dictatorship becomes either weak or overthrown, we do have the chance without destroying each other to develop a world that we all can live in.

That alternative is entirely possible, and should we not work for that?

Dr. KANTROWITZ. We can all remember the history of the Reformation, that it was a bitter time for many years, and suddenly one wonderful word was discovered, "tolerance."

Perhaps there will be some analog to that word that will be discovered nowadays.

Mr. FULTON. You see, rather than have all the witnesses here with their hands up in horror on what might come in the future, I am an optimist. I think the world will work out well. I predicted to General Gavin that the next war will be without casualties, that there will be counters up in the air, because whoever can get higher within a

certain range can control the earth. That means we will be moving the military power out into space; will it not?

Dr. KANTROWITZ. It is conceivable.

Mr. FULTON. If that is so, it will be, as I saw down in Guantanamo Bay with two Terrier rockets fighting a World War II plane. They knocked it down with much evasive action. There was not a soul in either one of them. It was very interesting.

So by a system of counters in outer space we would then have the next war, and when they had lost a sufficient number of counters they would know it was over, that was the end of the war. Could that not be?

Dr. KANTROWITZ. It is much farther than my own thinking has gone.

Mr. FULTON. That is why we are hearing you and you are hearing us. Thank you.

Mr. O'BRIEN. Mr. Feldman.

Mr. FELDMAN. Last Friday, Admiral Rickover stated he believed we should wait for atomic-powered rocket engines before attempting to launch a man in a satellite vehicle. Do you believe it is necessary to wait until then?

Dr. KANTROWITZ. I would say most emphatically no. I think that the advent of a powerful nuclear rocket, capable of lifting a manned satellite off the earth, is a very long way away. I think we must reckon with the fact that to carry a reactor aloft in a rocket requires us to have not only a nuclear rocket but one of tremendous reliability because an accident which could spread radioactive material over large parts of the earth would be very dangerous.

Mr. FELDMAN. We have seen pictures of large rockets blowing up on a test stand at the time of launching. In your planned manned satellite capsules would you have any emergency escape procedure?

Dr. KANTROWITZ. We have provided escape procedures which will be effective in all parts of the flight where there are likely to be any disastrous failures.

Mr. FELDMAN. What duration of flight would you propose for the first manned satellite flights?

Dr. KANTROWITZ. I would propose that we do something of the order of a few days. Shorter flights than that require a very great guidance precision and longer flights would require too much in the way of survival equipment.

Mr. FELDMAN. Do you believe that your manned capsule concept could be adopted equally well to the Titan?

Dr. KANTROWITZ. That is correct, it could equally be adapted to the Titan ICBM. The reason we have chosen the Atlas is that we believe it will be reliable before the Titan will be reliable.

Mr. FELDMAN. This morning Dr. Dryden told the committee that "Ion propulsion as a system is not ready for development, also ion propulsion must await the availability of ion rocket vehicles capable of placing hundreds of tons of payload into orbit." Do you agree?

Dr. KANTROWITZ. I most emphatically disagree with that statement.

Mr. FULTON. May I congratulate you.

Dr. KANTROWITZ. Thank you, sir. I would most emphatically disagree with that statement. I would say that electrical propulsion systems in the first place are not a dream. We have, for example, in

our laboratory a contract with the Air Force Office of Scientific Research for the study of such systems and we have achieved an electrical propulsion system which produces a jet which has some 100 times the velocity of the jet from a chemical rocket.

This makes possible the application of electrical propulsion systems to all flights outside the atmosphere. And I believe that the scheme for the future development of space flight will be the launching of orbital vehicles at low altitudes, 100 to 150 miles, by chemical launchers such as the ICBM rockets, that from there on electrical propulsion systems powered either by solar energy or by nuclear energy in various forms will be the practical propulsion system. I therefore have very little interest in projects which call for going beyond the satellite orbit with the use of chemical rockets at this time. I feel that these things will not be in the mainline of the development of space flight. I feel also that the development of electrical propulsion systems is something which should be undertaken now so that we can have more assurance that these devices can be built into our planning of space flight. We are undertaking such developments in our laboratory now.

Mr. FELDMAN. I think Dr. Dryden also told us that ion propulsion is not practical except for distance of a million miles from the earth.

Dr. KANTROWITZ. This is a mistake he made. I talked to him afterwards. He agreed that it was not right. What he was doing is imagining you could go far enough away from the earth so that you could lift yourself straight up. The practical way to do it is to go into a satellite orbit around the earth and propel yourself out in a spiral which can be done above the atmosphere at altitudes of more than 100 miles.

Mr. FULTON. When you have 10 pounds of thrust on an ion-propelled vehicle as against a weight of about a pound and a half at the distance of maybe 20,000 miles from the earth, that is quite a good leverage.

Dr. KANTROWITZ. At this point I agree with Dr. Dryden and disagree with you, sir.

Mr. FULTON. Why?

Dr. KANTROWITZ. Because the important thing in moving an object away from the earth is to overcome essentially its inertia. Its inertia is not affected by its distance from the earth.

Mr. FULTON. Yes, but when you have ion propulsion it builds up as gravity does at an accelerating rate so that it keeps adding on and adding on as time goes on, and while it is slow, you might have to make some circles in order to get the distance.

Dr. KANTROWITZ. That is right, and in my opinion this is the most promising method of going beyond the satellite orbit.

Mr. FULTON. That is what I think.

Dr. KANTROWITZ. This is something I feel quite enthusiastic about.

Mr. FULTON. Thank you. That is all I have.

Mr. FELDMAN. Can you compare the technical problems of reentry of a manned satellite orbit versus the Army's 150-mile manned rocket?

Dr. KANTROWITZ. I agreed quite completely with Dr. Dryden on this issue, that the problems that von Braun would face in sending a man up in a ballistic missile trajectory and bringing him back after reaching a peak altitude of 150 miles, are quite different from those one would face in reentry from a satellite orbit.

The only thing that you would learn is what happens to a man in 6 minutes of weightlessness. I feel therefore that this is another

project which is off the main track because I feel that weightlessness is not a great problem. Therefore, I am quite in agreement with what Dr. Dryden said.

Mr. FELDMAN. Your technical reputation in high-speed aerodynamics and reentry problems is well recognized. Do you feel that a manned satellite is a really feasible and important goal? Would you be prepared to undertake such a program, and what time scale do you see?

Dr. KANTROWITZ. I feel that the reentry of the manned satellite into the atmosphere, granting that the ICBM achieves its specified performance, is well within our current knowledge. We can do it, using well-known materials and well-known principles of aerodynamics. In regard to the importance of this, it is my feeling that manned space flight is part of the mainline of the development. There is, of course, a great amount of information to be obtained from instrumented space flight but I think that these things will only be important until one has manned space flights and then they will become of minor importance compared to what man will learn.

Mr. FELDMAN. What time scale do you see?

Dr. KANTROWITZ. I see a time scale of 2 to 3 years, granted a high priority but not a terribly expensive project, because it utilizes Atlas boosters which are already developed. It requires that the production of Atlases be slightly increased in order to provide test vehicles and it requires the development of the man capsule, itself. I think all of this will come to considerably less than $100 million.

Mr. FELDMAN. No further questions.

Mr. FULTON. Could I just finish a thought?

Mr. O'BRIEN. I was going to suggest that maybe the gentleman from Pennsylvania would like to ask this obviously well-qualified witness that question of his about pull versus drag, although to me the terms are synonymous.

Mr. FULTON. I have tried everybody and I don't know whether they can be a Navy lieutenant or not under the present examination. I would like to hear you as a fellow scientist.

Mr. O'BRIEN. The only comparison, and this is not scientific, all I can think of is an ossified fellow at a bar; he was not moving in any direction.

Mr. FULTON. We might ask you to put in the record what you think of that.

Dr. KANTROWITZ. Would you please state the question?

Mr. FULTON. The question is on a vehicle in atmosphere or space when the thrust equals the drag and the lift equals gravity, what is it doing?

Dr. KANTROWITZ. I would say that it was in straight level flight.

Mr. FULTON. In continuous, unaccelerated, constant level flight. I guessed at that but it was not right. I answered it that way on the examination.

Dr. KANTROWITZ. Did you pass or fail?

Mr. FULTON. Could it possibly be a plane when it comes to the stall point in its climb?

Dr. KANTROWITZ. No, the stall point of the plane is when it is decelerating.

Mr. FULTON. Right at the stall what is it?

Dr. Kantrowitz. You are decelerating, you are losing speed at that point, which is the fundamental reason you lose lift thereafter.

Mr. Fulton. One point where I would like to make a comment, because you are in this field: Going back to our ion propulsion, both you and Dr. Dryden are acting as if there was an object stationary in space, that the vehicle starts with ion propulsion from a dead start with plenty of inertia.

I would agree that if there were a dead inertia then it might be hard to start because there is nothing to start it against. But on the other hand, where there is a vehicle traveling at a speed that we have used to get out of the atmosphere around the earth, then the question is that when ion propulsion takes over, it then increases acceleration of the speed that you already have. Again from ion propulsion, to me, is that it keeps building up like going up a pyramid, a continuous acceleration, so that in time if you had a trip of a year with ion propulsion you would be going at a tremendous rate of speed which then, to use your own words, could be coasted almost anywhere.

You see, you could build it up and then coast it.

Dr. Kantrowitz. That is quite correct.

Mr. Fulton. Once you build it up with a ion speed, suppose you put it in the atmosphere with a tremendous orbit and you let it go for maybe 10 years, we might have fantastic speeds we don't know anything about. Isn't that right?

Dr. Kantrowitz. I would think in 10 years with any appreciable amount of acceleration you would approach velocities close to the velocity of light which would provide a sharp limit.

Mr. Fulton. One thing is sure: Neither you nor Dr. Dryden nor I know what the value of inertia is of objects in space that are away from gravity or electronic controls.

Dr. Kantrowitz. I disagree with that. If you remember the history of our understanding of mechanics, this was first achieved by studying objects in space and particularly by the orbit of the moon. Newton's first achievement of the real understanding of what was going on was by understanding the behavior of a body in space where it is simplest. This has been checked many times.

Mr. Fulton. You and Dr. Dryden are trying to take the position that a 10-pound thrust continuously accelerated on a magnitude of 1½-pound weight in space is not an effective propellent.

Dr. Kantrowitz. The next question is, what is the basis? In our own proposals for accelerating a manned satellite to a higher orbit, we have used thrusts as small as one-thousandth of a pound with effect. It takes time.

Mr. Fulton. Then you are very encouraging to me.

Dr. Kantrowitz. But we accelerate very slowly when we do that.

Mr. Fulton. That is right, but I have accepted that. I have spoken more of the fact that when (and you and I agree) we pass beyond the atmosphere—we are going at a pretty good speed, so that acceleration with ionic propulsion is added to the particular speed we had when we exited from the earth's atmosphere.

Dr. Kantrowitz. It is more efficient as you go to higher speeds, this is correct, but it still accelerates you very slowly.

Mr. Fulton. Thank you very much.

Mr. O'BRIEN. Doctor, I want to thank you for the committee and myself, first for your patience in waiting and, secondly, for your very interesting and informative testimony. We are grateful to you.

Dr. KANTROWITZ. Thank you.

Mr. O'BRIEN. If you care to you can expand your comments when you have an opportunity to edit your testimony.

I might announce for the benefit of the remaining members that we are meeting at 10 o'clock tomorrow morning in room 356, which I understand is just around the corner.

(Whereupon, at 6:05 p. m. the committee was recessed, to reconvene at 10 a. m. Wednesday, April 23, 1958.)

ASTRONAUTICS AND SPACE EXPLORATION

WEDNESDAY, APRIL 23, 1958

House of Representatives,
Select Committee on Astronautics and Space Exploration,
Washington, D. C.

The committee met, at 10 a. m., pursuant to recess, in room 356, Old House Office Building, Hon. John W. McCormack, Chairman, presiding.

Present: Representatives McCormack, O'Brien, Metcalf, Natcher, McDonough, Fulton, Keating, and Ford.

Also present: George J. Feldman, director and chief counsel.

The Chairman. The committee will be in order.

The first witness is Brig. Gen. H. A. Boushey, Deputy Director of Research and Development, of the United States Air Force.

We are glad to have you before us, General Boushey. We will be very glad to hear from you.

STATEMENT OF BRIG. GEN. H. A. BOUSHEY, DEPUTY DIRECTOR OF RESEARCH AND DEVELOPMENT, UNITED STATES AIR FORCE, ACCOMPANIED BY LT. COL. FRANK DILLON

General Boushey. It certainly is a pleasure to be here this morning, Mr. Chairman.

I have a few remarks which I have written to refresh my memory. With your permission I would like to read them now, if I may. They They should not be too long. It should not take more than 12 or 13 minutes.

Shall I proceed?

The Chairman. Yes, you may proceed.

General Boushey. Mr. Chairman and members of the committee, and counsel, man's future is inevitably linked with the problems which this committee is considering. Thus, I feel honored that you have requested me to appear before you today to present my views, views which I recognize may be controversial, but nevertheless, ones which I believe sincerely, and which I shall attempt to present clearly and concisely.

We in the military services sincerely pray that weapons of space may never be used, but, rather, that peaceful benefits of space may be freely enjoyed by all men.

However, I have been called before your committee as a military witness, and thus I shall try to limit my remarks to those which are pertinent to the military potential of space.

But at the outset, I would like to make one observation. Past experience has shown that some of our most respected thinkers have

failed to appreciate new concepts. Typical expressions of our military and scientific past come to mind—"Steam will never replace the sail;" "The airplane can never sink a battleship;" "Power can never be obtained from the atom;" "A jet engine will always be too inefficient to be useful," and, fairly recently, "The hydrogen bomb won't work."

So, I feel we should analyze proposals with intelligence and imagination, for again and again, the "absurd impossible" of today becomes the reality of tomorrow.

From a military consideration, the debate of the space age can be narrowed to two questions. These are:

1. Can space power provide significant military advantage? and
2. If this be true, what specific military applications of space power will give us the greatest advantage?

Now, without claiming to be the only persons who have considered these critical questions, we in the United States Air Force, on the basis of actual military experience, feel we can answer the first question in terms of plainest common sense.

For years our job has been to achieve, and at times to exercise, a dominant capability to deliver firepower against an enemy by military operations above the surface of the earth. In doing this job we have been, and still are, guided by one major premise, that a decisive margin of advantage goes to the nation whose delivery vehicles can attain the greatest speed, the greatest range, and the greatest altitude.

The battle tested validity of that premise has impelled the Air Force to continue its efforts to fly higher, farther, and faster.

The technical endeavors that have been accelerated and intensified by this program have produced truly spectacular results.

For example, the improvements in rocketry, guidance, and hypersonic aerodynamics which are incorporated in our intercontinental and intermediate range ballistic missiles are truly major technical advances. But these, and other achievements are well known to this committee and need no elaboration.

It is a fact that the first military space weapons will be the Air Force intercontinental and intermediate range ballistic missiles Atlas, Titan, and Thor.

To these should be added the Army's Jupiter and the Navy's promising Polaris.

While these missiles only remain in space a relatively short period of time, they do leave the sensible portion of the atmosphere and during this time they respond only to astronautic laws, the basic laws which control the motion of the bodies of our solar system.

Such weapons are space weapons, and they produce tremendous improvements in the range, speed, and reaction time of our Nation's deterrent force.

It thus becomes obvious that the answer to our first question: "Can space power guarantee significant military advantage?" is a decisive yes.

This brings us to the second question: "What other specific military applications of space power will give us the greatest advantage?"

And by "other specific military applications of space power," I refer to space vehicles which can operate above the earth's sensible

atmosphere for longer periods of time and which are not earth based. These space vehicles include primarily manned and unmanned satellites, piloted, maneuverable space craft, and eventually even an inhabited lunar base.

Nobody at this time can present a fully detailed chart of future space operations. There is too much still to be learned, and there are too many theories still to be tested to submit a bill of particulars.

But I do have several firm convictions regarding our development of space power.

First of all, I do not believe that machines alone, controlled from earth, can establish a capability to dominate space. I do believe that piloted vehicles are also essential to insure that our space systems can respond flexibly and promptly to unforeseen changes.

I also believe that on the spot exercise of human intelligence, judgment, and discrimination will be needed for effective control of space.

Undoubtedly various types of earth-circling satellites will prove useful, not only for military needs, but for peaceful purposes as well.

I am sure the committee already appreciates many of the valuable functions which such satellites can perform.

One of the most attractive features of an earth circling satellite is the tremendous improvement in telescopic and photographic resolution which is possible because of the total absence of atmosphere.

What may not be widely recognized is the degree of detail which could be distinguished from, say, a 500 mile orbit. With only a 40-inch diameter telescope, it is estimated that objects on the earth of a size less than 2 feet could be detected.

If a 200-inch diameter telescope, the size of the present Palomar reflecting mirror, were located in space at the "stationary orbit" distance of roughly 22,000 miles, objects on the earth approximately 17 feet in diameter could be viewed.

I believe man will be an essential element for such an observation platform. Even the problem of deciding where to look is a formidable one, and if left to a mechanical device the chances of profitable search and detailed scrutiny would be far less than if under the direct supervision of an intelligent operator who could immediately exercise the faculties of suspicion, comparison, and reason.

Such an orbiting reconnaissance platform might very well improve earth-based ICBM warning times by a factor of two. Enemy missiles as they rose above the atmosphere during launch could be detected clearly and warning transmitted to the free world in half the time of our best earth-based early warning systems.

Another function which I believe only man can perform effectively is that of interception and midspace rendezvous. At first, such missions probably would be for the purpose of refueling, thus permitting a manned, maneuvering space vehicle to receive fuel from an uninhabited tanker satellite which might have been circling in orbit for months or years.

If such refueling operations were not utilized, the size and costs of vehicles for true space exploration would be vastly greater, and our time-table for manned flight to the moon or Mars and Venus would be extended greatly.

Eventually, the capability to control space would be augmented by the ability of manned military space craft to make interception or rendezvous in space.

Various other types of unmanned earth circling satellites will undoubtedly prove useful, but a frequency overlooked requirement, that of maintenance and resupply, will require the use of manned space craft.

Malfunctions of automatic equipment do occur. Periodic replenishment of parts and fuel will be desirable and preferable to the alternative, uneconomical use of "one time disposable vehicles."

It is inconceivable to me that any method other than by manned maneuverable space craft could effectively perform this vital maintenance function.

But man's usefulness in space becomes most apparent when considered in relation to our only natural satellite, the moon.

I realize that many experts have had many varied opinions about the moon. I happen to be one that feels it will be extremely useful. These are my own opinions and if I may I would like to express them freely.

My personal conviction is that ultimately the establishment of an inhabited lunar base will provide numerous advantages, both civilian and military.

Materials synthesized from matter obtained from the moon itself could be used for construction, and the support of human life. Oxygen could be extracted from the ores of the moon, and even water could most probably be obtained from its minerals.

I have been told that magnesium silicate contains approximately 15 percent water in crystalline form. If that were not available, many of the hydrides could be used, the hydrogen extracted and burned with the oxygen to form water.

We don't know what the moon is composed of, but until somebody has a better guess, we have to assume it is composed of much the same stuff as the earth is.

As the Russians recognize and so stated in their space movie "Blazing Roads to the Stars," rocket fuels could be synthesized from lunar material. The cost is great, in both dollars and energy, to place any material at a location having only one-sixth earth's gravity.

Since the moon abounds in material, it is destined to become the launching site for further explorations of our solar system, and perhaps even the best supply base for lower orbit, earth circling satellites.

Lunar conditions would offer unparalleled advantages for astronomical observation. For example, today from the earth, using present telescopic and photagraphic equipment, it is possible to detect an object approximately one mile in diameter, or not a great deal larger than the Pentagon, including its parking lots, for the Pentagon building alone is over one-third mile in diameter.

If you have ever walked from one end of the parking lot to the Pentagon, you can appreciate that the complex is more than a mile in diameter.

Even assuming no improvement, a lunar station having no better optical resolution would be very useful. Worldwide weather surveillance needs resolutions of many miles, not feet, and would be of undisputed military advantage as well as peacefully benefiting mankind throughout the world.

But the optical resolution would improve considerably once beyond the earth's atmosphere.

Mr. Chairman, at this point, I have little demonstration. I will pass out two cards and a semitransparent screen. The screen scatters the light. If you will hold the transparent or semitransparent screen close to the black dot, you will see that it can be seen readily. If you move the scattering screen toward your eye, due to the scattering effect which is similar to that of the atmosphere, you notice the resolution disappears immediately.

This I have been told by reputable astronomers is a valid comparison of conditions as they would exist on the moon looking toward the earth. The transparent film represents the atmosphere immediately next to the earth's surface rather than vice versa, where you cannot obtain good resolutions.

I think the analogy holds up to the extent of making the point clear.

Looking through our atmosphere with scintillations, scattering and thermal disturbances limits of visual acuity through a telescope.

On the moon the only limitation is that theoretically obtainable through the best optical instruments which man can devise.

As a rough figure, I have been told a 5-fold factor of improvement with existing telescopic lens systems, photochemical processes and so forth, would automatically take place once beyond the atmosphere of the earth.

There would be a 5-fold improvement in "seeing," and thus the diameter of an object which could be detected on the earth's surface from a lunar observatory would then be approximately one-fifth of a mile, or close to 1,000 feet.

During the next 15 to 20 years, with the inevitable improvements in optics, photochemistry, and especially electronic amplification of light, it would seem quite conservative to expect great improvement over present-day astronomical detection capabilities.

Such improvement would then permit detection from the moon of objects on the earth of the order of less than 100 feet, or sufficient to distiguish individual aircraft or missiles.

Now, I am not extrapolating far beyond what is available today. I am using figures which astronomical experts such as Dr. Evans of the Sacramento Peak Observatory, Father Heyden of the Georgetown Observatory and Dr. Lee Devol of the Aeronautical Research Laboratory and others have given me.

A proposal has already been made to build a 400-inch telescope, one twice as big as the one at Palomar.

So less than 100 foot object detection on the surface of the earth from the moon, so I have been told by people whose opinions I respect, is quite possible.

And, last, as regards the moon, I personally believe it could, at some future date, be used as a secure base to deter aggression. Lunar launching sites, perhaps located on the far side of the moon, which could never be viewed directly from the earth, could launch missiles earthward. They could be guided accurately during flight and to impact, and thus might serve peaceful ends by deterring any would-be aggressor.

But as regards the entire subject of space control, one thing is certain, the inevitable advancement of technology.

As General Putt stated last week, we in the Air Force do not expect to marry present-day concepts and weapons to future space vehicles. We do not know what precise form these future weapons may take, but advances, in other branches of science, will surely keep pace with space technology and provide in the future defensive weapons of undreamed effectiveness.

Above all else, we must be bold and imaginative about the future of astronautics. We cannot be inhibited by the lack of imagination or our inability to foresee the exact application of each element of our national space program. We must support a broad program of basic and applied research.

We cannot be overly fearful of failures, and thus attempt only the sure things which result only in a short-term gain.

The cost of testing radical ideas and techniques to the point of determining their feasibility is small indeed when compared to the price of step-by-step small-gain advancements to existing equipment.

Simultaneously, we must not let our deterrent power deteriorate by concentrating too great a proportion of our research and development efforts in astronautics.

This may be a strange thing to hear coming from me, but I feel we must keep up our guard and not let it down at this time by concentrating too much on astronautics.

Because we are a peaceful nation and will never strike except in defense of freedom, we must keep our present deterrent power strong and improve it simultaneously with our advance into the space age. The cost will be high, but it is a price which we must accept if our way of life is to prevail.

The Russians do not appear to doubt the desirability of obtaining Soviet, manned space capability, nor do they discredit the worth of manned exploration of the moon.

My own views are that we can win the race for space if we do so desire. And I feel we must win it, so that all humanity can profit from these benefits which God has surely placed within the reach of man.

The CHAIRMAN. General, I noticed on page 11 of your prepared statement, you say:

> We surely will keep pace with space technology and provide in the future defensive weapons.

That also might be offensive weapons, too?

General BOUSHEY. It could be, sir.

The CHAIRMAN. Mr. Metcalf.

Mr. METCALF. Mr. Chairman, I think the General has given us a very hopeful and optimistic statement.

You have read the testimony before this committee where some say there is no use getting on the moon. Others make such statements as yours, that it is very important, both to our defenses and for various civilian uses that can be made of it, but our immediate concern is how to achieve those objectives.

Now, with your experience in the Air Force, working in the research programs, what would you do if you were recommending the creation of a new department to achieve this base on the moon that you want?

General BOUSHEY. Mr. Metcalf, of course, I am aware of what other people in this field have testified and even said in print and privately. I could not help being aware of these things.

I am also aware of the proposal before the Congress to create a National Aeronautics and Space Agency.

In my opinion, having worked for many years with NACA, which would be the predecessor of that organization, I feel that we understand each others problems, we work quite harmoniously and the combined effort of the military and the scientific, to me, is something which historically has proved quite successful.

I am thinking of things in the past like the Lewis and Clark expedition where the military helped. It was opening the Northwest and it was at that time scientific.

I am thinking of Captain Cooke's voyages to the South Seas, done by a combination military, then naval—scientific effort.

This is how I feel this Nation could best go to the moon, or achieve the space efforts that I feel are required.

Mr. METCALF. I appreciate that the NACA has made an enviable record, both in research and development, and in public relations with the people with whom it has worked. But do you think that blowing up or expanding the NACA is the best way to do this job, or is it only one way to do the job?

General BOUSHEY. I would not pretend to be the expert and say there is only one way to do it, sir. In my opinion, greater expansion or blowing up of the NACA into the NASA would not be necessary.

The military services have spent many millions of dollars to obtain much of the needed equipment. I think this can be used harmoniously and effectively as a joint team effort.

Whether it is the best way, or the only way, sir, I could not say.

Mr. METCALF. We want to do it the best way, if we can. You have read the proposed legislation?

General BOUSHEY. I have, sir.

Mr. METCALF. Are you satisfied that the interest of the Air Force, the interest of the Defense Department and of the military in general are protected in that proposed legislation?

General BOUSHEY. Speaking frankly, for myself, I would like to see in the law a provision that uniformed representatives of the three services would actually be on the 17-man body rather than leave some doubt, as I believe the present bill does.

This is my personal view, though.

Mr. METCALF. Thank you.

The CHAIRMAN. Mr. Natcher.

Mr. NATCHER. General, is the Air Force experiencing difficulty in securing trained people for your research and development program?

General BOUSHEY. If I understand the question, you are talking about contractor employees, or governmental employees, or both?

Mr. NATCHER. Both.

General BOUSHEY. I would say there is no difficulty, sir, in obtaining effective scientists and engineers through our contract efforts, but obtaining adequate experienced enough engineers or scientists through the civil service hiring procedures, I do feel there is a great difficulty.

Mr. NATCHER. Do you feel that here in this country the number of trained people is greater than in the Soviet Union today?

General BOUSHEY. I do not have knowledge about that, sir. From my general understanding, there is even an argument of the definition

of what is trained as compared to the Soviet techniques and our techniques.

I would guess at the lower level the number of technicians in Russia exceeds ours.

Mr. NATCHER. It has been stated from time to time that the United States has lagged behind from the standpoint of science and technology. But, General, is not a great deal of this based on the fact that Russia just during the past few years has suddenly blossomed forth as far as science and technology is concerned? Their achievements are of the past few years, beginning with the close of the World War II. Do you agree with that?

General BOUSHEY. Yes, sir; with a few minor exceptions they had a known interest in rocketry that went far back beyond World War I.

If you say a few years, the great impetus that the Russians received from the capture of the German scientists at Peenemunde in 1945, some 13 years ago, I believe is the basis of their present success.

Mr. NATCHER. General, you would not say it was entirely based on the seizure and capture of the German scientists, would you?

Do you not have to consider the fact that since World War II the Soviet Union has speeded up its school program, from the standpoint of development of trained personnel in the field of science and technology. In fact, testifying before our committee, Dr. von Braun stated very emphatically that in his opinion Russia did not secure from the captured German scientists everything that people in this country believe they secured.

General BOUSHEY. I agree with you wholeheartedly. What I meant in the immediate post World War II years is that what the Russians saw and learned from the Germans gave them the impetus and I think after about 1953 or perhaps earlier, they were able to carry on by themselves without the support of the German scientists.

Their educational program had come to that point in its abilities.

Mr. NATCHER. General, I believe you stated in answer to a question by Mr. Metcalf, my colleague, that you have examined the proposed bill before the committee?

General BOUSHEY. Yes, sir.

Mr. NATCHER. Do you agree, General, that this should be a civilian controlled agency?

General BOUSHEY. I do, sir, with the statement that I have already made, I believe the uniformed services should be represented on the 17-man board.

Mr. NATCHER. In other words, one member from each branch of the armed services?

General BOUSHEY. Yes, sir. One uniformed member.

The CHAIRMAN. Why do you want one from each of the branches, General? Why not from the Defense Department?

General BOUSHEY. Well, sir, I wonder if the services will receive adequate representation. The Department of Defense is a fairly large organization, as you know, and the facilities are spread across not only our continent, but some of our Pacific possessions as well and other parts of the world.

I feel it would take three people to justly represent all this knowledge, effort, and the facilities that are available on this board.

The CHAIRMAN. What about a liaison committee? Suppose this committee, in its judgment, should incorporate provisions providing

for a liaison committee between the new agency and the Defense Department?

General BOUSHEY. It might be very helpful, sir.

The CHAIRMAN. I mean that would be in addition to representation on the 17-man board, if that should stay in the bill.

Of course, the provision in the bill provides at least one. It does not confine it to one.

General BOUSHEY. Yes, sir; that is my understanding.

The CHAIRMAN. I was just exploring. If the committee in its judgment were to provide for a specific number of military representatives on the board, the 17-man advisory board, and it should be more than one, what is your opinion as to whether the number should be specified, with the Secretary of Defense having discretion to make the appointment?

General BOUSHEY. That might be a very adequate solution, sir.

The CHAIRMAN. In other words, if we cannot rely on his judgment, as to fair representation of the component parts of the Defense Department, then it is rather unfortunate.

General BOUSHEY. I agree, sir.

The CHAIRMAN. In other words, either 3, 1 from the Army, Navy, and Air Force, or 3 to be appointed by the Secretary of Defense.

General BOUSHEY. Yes, sir.

The CHAIRMAN. I think there is a lot of merit to liaison in these days, but there is no question we have to rely tremendously on the military. We just have to be practical.

I believe in civilian control, but I am not ignoring the importance of the military in the world of today and in the foreseeable future.

It means that the military, while not in a primary position, should not be put in a subordinate or secondary position.

As a matter of fact, the AEC really started out with a military emphasis.

General BOUSHEY. Yes, sir.

The CHAIRMAN. It was in 1954 that the transition took place, so far as civilian control is concerned. In 1954 they changed the AEC over to its present setup.

Under that, the military considerations were profoundly appreciated, as they should be.

General BOUSHEY. Yes, sir.

The CHAIRMAN. I think we can work it out. There will be no difficulty between what you have said. There is nothing inconsistent that I can see between what you have said and the views of most members of the committee.

Pardon me, Mr. Natcher.

Mr. NATCHER. General, do you agree that in taking that trip to the moon the spaceship would have to be as large as the Washington monument?

General BOUSHEY. No, sir; I don't.

Mr. NATCHER. What size spaceship could we use to take this trip to the moon, General?

General BOUSHEY. That would be a very hard question to answer, sir. As I mentioned, in my prepared statement, I think we can cut down the total size by putting fueling tankers in orbit and then a relatively small vehicle could get in the orbit velocity, refuel, go to

the moon, put an orbiting portion of itself with fuel in orbit around the moon, go to the moon, land.

Maybe the first man would stay there only long enough to erect some automatic reporting equipment, come back to the moon orbit, get the fuel he left there, come back to the orbit around the earth where there is more fuel and pick up fuel necessary for reentry.

The final vehicle that would land on the earth might be 12,000 to 15,000 pounds. The total size, I have been told, would be close to perhaps 900,000 pounds total if you consider all the boosters and stages to put these various things in orbit that you could use.

But, by orbiting, this is the ultimate in staging and you can cut down the total size and cost drastically.

Mr. NATCHER. General, do you have in the Air Force a timetable you are following now from the standpoint of outer-space exploration?

General BOUSHEY. Not to any degree in the future. We think the first steps, of course, should be to get unmanned satellites up and useful, then continue on taking the first steps, putting man in orbit.

Again, my personal view is the stationary orbit and the moon are two very important goals. Beyond that I think we should wait until we learn a little more before we fill in too many details.

Mr. NATCHER. Do you believe in 1958 to 1960 we might shoot a rocket close to the moon, then impact on the surface of the moon?

General BOUSHEY. Yes, sir.

Mr. NATCHER. General, do you further believe that from 1964 to 1966 it will be possible to land a vehicle on the moon with proper instruments and also to send manned rockets followed by scouting parties?

General BOUSHEY. Yes, sir. Unmanned, I think we might do it earlier than 1964 or 1966.

And with a man landing on the moon, returning to the earth, my own particular figure is around 1966.

Mr. NATCHER. Do you feel, General that in the year 1970, or sooner, we might be able to establish a permanent moon base and have a supply system set up and maintained at this particular base under our present Air Force research and development program?

General BOUSHEY. No, sir; I do not think so, because I will state generally I do not think the present program is of the scope you outlined. It may grow to that in the future.

Mr. NATCHER. General, you agree that this is one of the most important problems confronting the American people today?

General BOUSHEY. I certainly do, sir.

Mr. NATCHER. Are we warning our people sufficiently and advising them of the importance of this particular program? Are you doing it in the Air Force, and do you feel that the other branches of our military service are accomplishing this purpose?

General BOUSHEY. I will try to answer that as best I can, sir. I do not know if the services are doing their utmost, or what I would consider adequate to warn the people.

I do not think any better warning could be given any nation than Sputnik I and II. I am afraid some of the effect of that may have worn off.

I feel the people in the military services do try at every opportunity to bring to the attention of the American public the seriousness of the situation.

Mr. NATCHER. General, I certainly agree with you that some of it has worn off and we are now going back to our old complacency stage since we succeeded in placing our satellites in orbit.

But you agree that now it is imperative that we not lose any time in the development of our program?

General BOUSHEY. Indeed I do.

Mr. NATCHER. Thank you.

The CHAIRMAN. Are you acquainted with the Riehlman Subcommittee of 1954?

General BOUSHEY. I am acquainted with it, but I am not acquainted with the details.

The CHAIRMAN. Have you read the report?

General BOUSHEY. Parts of it.

The CHAIRMAN. Has the Air Force offered inducement and encouragement for officers to continue in specialized fields, particularly in the field of science and research and technology?

General BOUSHEY. Yes, sir; it does, in the way of advanced technological training and continuing assignments, we hope, in a field of great interest.

I think to the man that is interested in science, the ability to work and do something useful is even more important than the pay received, sir.

The CHAIRMAN. You cannot ignore that, either.

General BOUSHEY. No, sir.

The CHAIRMAN. But there has been a change in the last 3 years in connection with recognition of the importance of research and development?

General BOUSHEY. Yes, sir; I think so.

The CHAIRMAN. And particularly having trained officers, young men, starting out and making a career of it?

General BOUSHEY. Yes, sir; I think it was prior to 3 years ago we even changed the career name and number so that people specializing in research and development could specialize in that for a career.

The CHAIRMAN. And the opportunity of advancement in rank?

General BOUSHEY. Yes, sir.

The CHAIRMAN. I would have that ambition, myself, if I were in either one of the branches of the service. That is a human trait.

Are there any questions, Mr. Fulton?

Mr. FULTON. General, we are glad to see you here today, because we know of your distinguished record and your forward-looking approach to these matters of space.

Is not the problem of space the problem of the highest strategic urgency for the security of the United States?

General BOUSHEY. I agree it is, sir. I put out this one caution, though, that we don't take away our present deterrent for something 10 to 15 years in the future because we might make ourselves too vulnerable in the interim.

Mr. FULTON. So that this space program should not replace our current military security programs within the Air Force or on the ground, but should be in addition to it?

General BOUSHEY. In my opinion, sir, it should be in addition or a judicious balance.

Mr. FULTON. In order to expedite a quick moon shot, would you develop at the present time any propellents or engines of greater magnitude of efficiency and power?

General BOUSHEY. Indeed I would, sir; and this is already in the beginning stages.

Mr. FULTON. Would you favor the development of the million-pound-thrust engine at the present time?

General BOUSHEY. Yes, sir.

Mr. FULTON. How fast a program would you put on to get that?

General BOUSHEY. Personally I would try to see it through development and in the firing test stage in 5 years, sir.

Mr. FULTON. Once we had a million-pound thrust in the United States we could get up into orbit weights of considerable size, could we not?

General BOUSHEY. Yes, sir.

Mr. FULTON. I was very much interested in your comment on the fact that once we leave the earth's air and atmosphere that there might then be a change in the vehicle's type of propellant in the so-called moon shot.

General BOUSHEY. Yes, sir.

Mr. FULTON. Under those circumstances, would you then recommend that the United States Government proceed with an accelerated program of ion propellants investigation and study?

General BOUSHEY. Yes sir. I believe other witnesses have already testified about the utility of ionic propulsion.

Mr. FULTON. But you do feel it is worthwhile and it should be gone into for use in the outer atmosphere and space?

General BOUSHEY. Immediately, sir, if for no other use than attitude control alone.

In other words, for precise observation or even for reentry the vehicle must be alined very precisely.

This can be done most efficiently and effectively by ionic propulsion and in a relatively short time period.

Mr. FULTON. One of the good things about ionic propulsion, even though it is slow to start, is that it has continuous acceleration, does it not. It has very little weight because of the fuel?

General BOUSHEY. Yes, sir; my understanding is that it is the most efficient means of propulsion today although the propulsion rates are very low, a thousandth of a G acceleration.

Mr. FULTON. At a distance of 20,000 to 25,000 miles from the earth, even a few tons of material, or substance, at the earth's surface, would be only 1, 2, or 3 pounds in weight?

General BOUSHEY. Yes, sir; but the mass would still be there.

Mr. FULTON. That is my next point.

Do you feel that the mass is a complete obstacle to the use of ion propulsion the way some people have said, that we might have to have a sail with 50 million square feet of surface which would increase the mass tremendously in order to have ionic propulsion?

General BOUSHEY. Are you referring to photon propulsion, sir? The sail makes me say photon.

Mr. FULTON. Yes, sir.

General BOUSHEY. Yes, sir; I have heard very large areas are required for photon propulsion, or the pressure of light.

Mr. FULTON. Actually, what I am bringing up is this: When we have a large mass outside the earth's atmosphere and we talk of the ionic or photon propellent, which is small in relation to the mass, and a small power, is the mass itself enough to stop us on either ion or photon propulsion?

General BOUSHEY. I cannot see it, myself, sir, why there would be any limitation.

Could I give a little example?

Mr. FULTON. I would like it.

General BOUSHEY. I used to work with a technician. I would always propose a number of "out in the blue" ideas and try them on him for size. He always had a good expression. He said, "Colonel, (f) equals (ma). Force equals mass times acceleration." This is his way of saying you cannot beat the laws of nature.

In your case "(f) equals (ma)", force equals mass times acceleration. I can't see why mass should be any hindrance over the use of small acceleration.

Over a period of time we could develop tremendous velocities.

Mr. FULTON. On the exit from the earth's atmosphere we would have to go at a considerable speed in order to get out. Then, if the ion or photon propellent took over, it would mean merely to maintain the speed which is almost coasting.

General BOUSHEY. Yes, sir.

Mr. FULTON. So that we might need a little force in relation to the mass. Is that not right?

General BOUSHEY. Yes, sir.

I don't know if you are aware of some proposals to use ionic propulsion to power gigantic freighters of the future to the vicinity of Mars or Venus. These might take many, many years, but who cares if you are only transporting supplies? You can do it most efficiently.

Mr. FULTON. With earth's gravity accelerating at 32½ feet per second, it would not take many seconds to get a terrific speed, if we had no drag.

General BOUSHEY. That is quite correct, sir.

Mr. FULTON. Then, with either photon propellent or ionic propellent, while the speed and power might be slow to begin with, with a continuous acceleration for maybe 1 to 10 years, we might even be approaching half the speed of light?

General BOUSHEY. So I understand, sir.

Mr. FULTON. So that my final conclusion is that you would recommend proceeding with study and investigation of both ion propellent as well as photon or light propellent?

General BOUSHEY. Indeed I would, sir.

Mr. FULTON. There have been some questions raised by several witnesses that photon propellent was not even worth a study. Do you disagree with that?

General BOUSHEY. I am not sure I understand the term "photon propellent," sir. My understanding, and I could be quite wrong——

Mr. FULTON. Photon engine, we call it.

General BOUSHEY. It is a light-pressure engine. A propellent would merely be used to convert the energy of the fuel into some light condition or at least develop a light pressure.

Mr. FULTON. Being a Navy man I was using propellent in the nature of a propellent which pushed. I have asked that a glossary be prepared of all these scientific terms so that we would have an overall dictionary of these scientific terms for scientists, military, laymen, and Congressmen.

Do you agree that should be done?

General BOUSHEY. Yes, sir; very much. There has been an attempt at this, a small start by the Air University, but this is only within one service.

Mr. FULTON. We ought to have an official Government glossary or dictionary of official scientific terms so that we can have a place to look to see what we mean by our words.

General BOUSHEY. Yes, sir. If you don't have a little copy of this glossary of astronautic space terms, I will be glad to give you one. It is the Air Force glossary only. I agree we need to agree on what we are talking about, the definitions.

Mr. FULTON. How can we presently translate foreign languages, particularly Russian, into a scientific jungle, such as we have in the words on space, when many people do not use the words in the same context?

General BOUSHEY. That is quite true, sir. Like the title of the TV program Sunday, Blazing Roads to Stars. I am not sure of the translation, if they meant they were blazing as you blaze a highway through a mountain, or they were blazing because of the rocket flame. That is an example of what you are talking about, sir.

The CHAIRMAN. Mr. Keating.

Mr. KEATING. General, before we get to ion or photon propulsion, is it not pretty generally agreed that nuclear propulsion could come quicker?

General BOUSHEY. I am not sure in my own mind it could, sir; and they are so vastly different, whether they could or could not, I think we have to go ahead with both.

It would be very difficult to have a human in the environment near nuclear propulsion while it is operating.

Mr. KEATING. That is the great difficulty with nuclear propulsion?

General BOUSHEY. One; yes, sir.

Mr. KEATING. That has not yet been solved?

General BOUSHEY. No, sir, but even with nuclear propulsion I believe Mr. Fulton points out that ionic propulsion is more efficient as far as specific impulse goes.

Mr. FULTON. I agree with you.

Mr. KEATING. I want to see if I can get this straight in my own mind. You are talking here to most of us, who are not scientists, about this refueling process in outer space which intrigues me considerably.

Now, the part that particularly intrigues me is how the refueling vehicle and the refueled vehicle marry up out there in outer space.

When they get there in order to get into orbit they both have to be going 18,000 miles an hour.

General BOUSHEY. Yes, sir; depending on the altitude of the orbit.

Mr. KEATING. If you can get them both in line with each other, then it is just as if they are both standing still.

General BOUSHEY. That is right.

Mr. KEATING. If I oversimplify this you tell me so, but that is the way it strikes me.

In other words, the earth is going around pretty fast right now, and you and I are going with it, but we are going at the same rate, so we are here stationary, vis-a-vis each other. Is it the same principle when you get out there in outer space?

General BOUSHEY. I think it is, sir, but to get exactly into the same plane of orbit and to precisely adjust speeds is one reason I felt that a human operator making the rendezvous and refueling will be necessary.

There is one helpful thing. As you go farther and farther out in orbit the velocity decreases. So if you can visualize joining up as in formation, which we do in the air frequently, you would travel on the inside orbit and then pull up.

In other words, you go up into a larger circle and thus kill your speed and join up. I think you can do the same thing from orbit, coming in at a lower orbit altitude and then thrusting outward, which would slow you down.

How it will be done, I will not predict, but there are certain physical laws that help rather than hinder.

Mr. KEATING. You would have to use electronic equipment in connection with locating this satellite that you are trying to marry up with.

General BOUSHEY. Yes, sir. I hope the rough rendezvous could be guided from the ground. Then as the man came in proximity to this big refueling satellite, or you might say space fuel truck, then he would take over with his self-contained electronic instruments and effect the final rendezvous and refueling.

Mr. KEATING. In mentioning these ways, of course, the advantage of the refueling arrangement—indeed, the necessity of refueling if you use present fuels—is apparent because you just could not get off the earth with any conceivable amount of power filled with liquid propellent stuff to go to the moon.

Do I understand that would take 900,000 pounds that you would have to propel into space to do that?

General BOUSHEY. No, sir. I cannot give you an exact figure.

Mr. KEATING. But it would be an astronomical figure?

General BOUSHEY. No, sir; I think it would be a fairly modest figure Say the final payload that is going to return to the earth is 15,000 pounds. You must work the problem backward.

This 15,000 pounds then has to get into orbit around the earth before it reenters. Then it has to get from the moon's orbit down to the refueling orbit around the earth.

Then it gets from the orbit of the moon to the moon's surface, back from the moon's surface, back to the fuel tank it left off in orbit.

Then it goes from that orbit back to the first refueling orbit and back to the earth.

In that way you can calculate what the total takeoff weight must be.

Mr. KEATING. It would have to drop 2 or 3 engines on its way?

General BOUSHEY. It could drop off engines or fuel tanks, whatever you have.

Mr. KEATING. You could drop 6 or 8 if you had them?

General BOUSHEY. Yes, sir.

I quote a figure I saw close to a million pounds for one vehicle which was shown which might do the trick. I would hate to be quoted that that is the minimum size or that is the maximum size. It just gives an order of magnitude, sir.

The CHAIRMAN. Will the gentleman suspend right there.

The Chair recognizes Mr. Fulton to present a very distinguished guest.

Mr. FULTON. We have with us today Dr. J. C. Warner, president of the Carnegie Institute of Technology at Pittsburgh, a scientific school with 5,000 students. He is a distinguished member of the American Academy of Science, as well as a member of the General Advisory Committee of the Atomic Energy Commission.

He has done many distinguished things and received many awards for his service in science to our country.

I am glad to welcome him on behalf of the committee and say to Dr. Warner that we are looking to schools such as the Carnegie Institute of Technology to expand in order to train this very select group of thinkers who are going to be necessary for solving these problems of outer space.

The CHAIRMAN. We are glad to have you with us, Dr. Warner.

Dr. WARNER. Thank you very much.

The CHAIRMAN. All right, Mr. Keating.

Mr. KEATING. I realize that we can conceive, at least now that we have come to Washington, we can conceive of what a million means.

You think that something perhaps in the neighborhood of that weight, when it left the ground, could project a 15,000-pound payload to the moon?

General BOUSHEY. Yes, sir; as I have outlined. If you would like, sir, I could have some calculations run by our technicians and give you a more precise answer.

Mr. KEATING. I think in this record it might be well, because that is the only thing you can do today with existing hardware.

You do not have the nuclear problem solved; you do not have the ion problem solved; you do not have the photon. You could not do that today, but that is the first thing you could aim at doing, probably, using present propellents.

General BOUSHEY. Yes, sir; and pure ballistic type of liftoff.

If you want to combine and perhaps get a hybrid, you might take advantage of aerodynamic lift as well.

I have also seen some reported pictures of Russian vehicles that sprout wings to help in the exit.

Mr. KEATING. After they get up there, they sprout them?

General BOUSHEY. Yes, sir. They could start from the ground as an air breathing vehicle. There are many ways to do this. I would not say that the ballistic million-pound approach is the best way. There might be better, cheaper, and smaller ways to do the same job.

Mr. KEATING. What thrust would it require to put up a million pounds of weight?

General BOUSHEY. In orbit, sir?

Mr. KEATING. We are talking about this million pounds with a 15,000-pound payload that returns to the earth.

General BOUSHEY. I don't know, sir. I would hate to give a quick guess.

Mr. McDONOUGH. Is there a definite ratio on thrust or weight?

General BOUSHEY. Yes, sir, 1.2 or 1.3 is a ratio on a purely ballistic way of doing it, but I feel we are not smart enough to say that is the only way we can do it.

I think we can do it better and more effectively in the future. Getting to your question, ionic propulsion would not be any good getting you from the ground. That is quite true.

But if you are in the airless surface of the moon, which to all intents and purposes is a pretty good vacuum, you might be able by catapulting with an electric catapult or something, to get the vehicle at a high enough speed.

I think escape speed is 1.7 miles per second, from the surface of the moon as against 7 miles per second from the earth. Then you might take over with photon, or I prefer ionic, propulsion and go on from there.

It might be a very small vehicle, sir.

Mr. KEATING. It looks as if eventually that is what you would have to do?

General BOUSHEY. Yes, sir.

Mr. KEATING. Now, I want to be sure I have in my mind the great advantages which you foresee in viewing the earth from the moon. Did I understand that at 22,000 miles out from the earth you could see a 17-foot object on the earth?

General BOUSHEY. That is a conservative estimate. You could probably see smaller than that.

Mr. KEATING. So as to discern what that object was?

General BOUSHEY. No, sir; that is the limit of detection. You might need a little larger object to decide what it was.

It not only is a matter of shape, but it is a matter of light contrast as well. This is why photo interpreters use the shadows to identify objects more than the resolution or shape of the object itself.

Mr. KEATING. Do you mean you could do that with existing equipment?

General BOUSHEY. With a 200-inch telescope, which has been in operation at Mount Palomar for 15 years or more, if this were placed in a 22,000 mile stationary object, this is a resolution you could see and this is a conservative estimate.

Mr. KEATING. Now, 22,000 miles up in space is a little high, even for this committee. Suppose you are only two or three hundred miles out in space, or, say, 500 miles, how small an object could you see?

General BOUSHEY. I think the figure turned out to be about 1¾ feet. I referred to it as approximately 2 feet from a 500-mile orbit. That is using the 40-inch mirror, sir, not the 200-inch.

Mr. KEATING. Would it be practical to use a 200-inch mirror?

General BOUSHEY. It might be, sir, but the rate at which this satellite would be traversing the surface of the earth might cause your rate of traverse, your image speed to be so high you could not compensate for it.

You are looking at a pretty small patch of ground with a great big mirror. Then I imagine this big mirror, even in space where you don't have the disadvantages of gravity, it would be pretty hard to put it up there and keep it there.

Mr. KEATING. At 500 miles up you could see a 2-foot object sufficient to identify it?

25973 O—58——35

General BOUSHEY. I did not say identify it. It might take twice that size to identify it, but it could be detected.

Mr. KEATING. It still is pretty staggering. You think a 4-foot object could be identified from 500 miles?

General BOUSHEY. I wanted to sound somewhat conservative, sir, but the way it was told to me by a physicist who, I believe, is very expert in his field, you could see a man, you could detect his arms and legs, but you could not tell who he was.

Mr. KEATING. From 500 miles?

General BOUSHEY. Yes, sir.

Mr. KEATING. You could tell it was a man?

General BOUSHEY. Yes, sir.

Mr. KEATING. I do not mean a man or woman.

General BOUSHEY. No, sir You could probably tell it was not a four-legged beast.

Mr. KEATING. You could tell it was a two-legged animal at 500 miles?

General BOUSHEY. So I have been told, sir. I went to the trouble before appearing before your committee, Mr. Chairman, to check with four astronomers who have enviable reputations. I have used the most conservative of any of their estimates as to what is possible with optics.

I am not an expert in optics, myself, sir

Mr. KEATING. So that you could certainly tell at 500 miles up the nature of an entire building, as to whether it was a factory or house, or what it was?

General BOUSHEY. Provided it was not during a condition of cloud cover or night

Mr. KEATING. I am assuming good conditions.

General BOUSHEY. Yes, sir. These are under the best of seeing conditions, these figures I have quoted.

Mr KEATING. I know I have displayed great ignorance in some of my questions, but I am starting from scratch on a lot of this.

Why do you not encounter the same difficulty in looking down at earth that you would on the earth looking up 500 miles into the air?

General BOUSHEY That little card was supposed to show why.

Mr. KEATING. I did not get that. In other words, why is not that cloudy result achieved whichever way you look?

General BOUSHEY Maybe a homely example, sir, if you look through a pair of binoculars and your hand has tremors, if affects the image. If you had the big binoculars over there and it had the same tremors, it would not affect the image as much.

That is the way I explain it to myself, but again, I am not an optical expert, sir.

Mr KEATING. Thank you, General, you have been very helpful.

I want to compliment you on your testimony, particularly on the simplicity of it and the down-to-earth character of it, which is very helpful.

General BOUSHEY. Thank you, sir.

The CHAIRMAN. Mr. McDonough.

Mr. McDONOUGH. Continuing Mr. Keating's questions about an object, how accurately can we reflect an object on the moon from a satellite with apparatus on the satellite and reflecting back what it says?

General BOUSHEY. Are you talking about optical viewing, or reflecting by some electronic means?

Mr. McDONOUGH. By electronic means.

General BOUSHEY. Sir, I cannot help you on that. I do not know much about that area.

Mr. McDONOUGH. I have no other questions.

General BOUSHEY. I am sorry, sir, that is something I hesitate to answer.

The CHAIRMAN. I do not know of any better answer than a frank one.

Mr. Metcalf.

Mr. METCALF. You mentioned in this projected trip to the moon that you are going to orbit around the moon.

General BOUSHEY. Yes, sir. Not I.

Mr. METCALF. You and Admiral Rickover are going to stay home. That space craft of yours is going to an orbit around the moon. Will you tell me something about orbiting around the moon? What is the distance at which an orbit can be reached and what is the speed?

General BOUSHEY. I have heard no limit to how close a vehicle can orbit around the moon. It depends on the traces of atmosphere and how accurate the orbit is around the moon.

If it were completely circular and the moon is absolutely circular and the high craters did not get in the way, I guess you could do it at an altitude of several hundred feet above the moon.

Mr. METCALF. What would the speed have to be?

General BOUSHEY. I have not worked that out. I can furnish it to you later, sir.

Mr. METCALF. You are going to have a satellite with another satellite orbiting it?

General BOUSHEY. I do not see any point in orbiting so close to the surface of the moon. What would be the reason?

Mr. METCALF. I do not know. I was wondering how far out. I had no idea you could orbit within a hundred feet. I was thinking of an orbit of 50 or 100 miles.

General BOUSHEY. Could I give you an example that might help you, sir?

Mr. METCALF. Yes.

General BOUSHEY. The diameter of the earth is roughly 8,000 miles. We are talking about a satellite orbit 150 miles from the surface of the earth.

If you drew that graphically you would have a great big earth, and then a tiny orbit altitude you could hardly see. So, relatively, we are orbiting relatively close to the earth now.

The moon is 2,000 miles in diameter. And it has no atmosphere. So I don't see any reason why you could not orbit just grazing the tops.

The CHAIRMAN. Mr. Feldman.

General BOUSHEY. Pardon me, sir, we have the answer to the question.

Colonel DILLON. The velocity of the orbit would be less than 7,750 feet per second to orbit around the moon.

Mr. METCALF. How many miles is that?

Colonel DILLON. That is a little bit more than a mile a second.

Mr. McDONOUGH. Mr. Chairman, I have one question.

You speak about no atmosphere around the moon because we find no cloudy envelope around it.

Is it possible that there is some invisible gas around the moon that we have not discovered?

General BOUSHEY. Small traces; yes, sir.

As to any appreciable quantity, I think the astronomers could answer definitely no. When a star passes behind the moon, the refraction that would take place if there were appreciable atmosphere is not observed.

Therefore, any atmosphere on the moon may lie in low crater. It may be that there are such heavy gases as argon or krypton, heavy gases that do not escape, in accordance with the laws of physics, the gravitational attraction of the moon, but if there are gases they are heavy gases only and there are only small traces in the low levels on the moon. You must recall in the daytime the temperature gets above that of boiling water so it would drive off the light gases, and at nighttime, which is 14 days, the temperature gets down to minus 240° Fahrenheit.

So gas might freeze and remain in the solid state.

Mr. McDONOUGH. Have there been any spectroscopic studies of the atmosphere surrounding the moon or any reflection on the moon which may indicate presence of certain elements?

General BOUSHEY. I don't know of any, personally, sir, I have only read the theories.

So far from my knowledge I have heard no factual evidence that any gas existed or having been detected on the surface of the moon.

Mr. McDONOUGH. We have researched our more information about the moon than any other planet; have we not?

General BOUSHEY. Yes, sir.

Mr. McDONOUGH. We know little about Mars, except at the other end of the telescope?

General BOUSHEY. That is right; and a radio telescope, both.

The CHAIRMAN. Mr. Feldman.

Mr. FELDMAN. General, you said that you would like to see representatives of the 3 services on this 17-man advisory board.

General BOUSHEY. Yes, sir.

Mr. FELDMAN. The NACA setup as it presently exists has a 17-man advisory board. Is that right?

General BOUSHEY. I believe you are correct, sir. I believe you know more than I do about it.

Mr. FELDMAN. And the Director is under the Board, that is, it has control, it sets the policy?

General BOUSHEY. My understanding is that Director is appointed by the Board.

Mr. FELDMAN. Is that right? And the primary duty of the NACA at the moment is to do research projects which other agencies ask them to do for them. Is that right?

General BOUSHEY. Yes, sir; and I believe also undertake those that in their opinion they should be doing themselves, not upon request.

Mr. FELDMAN. They do not build any hardware themselves. Is that correct?

General BOUSHEY. Hardware for test purposes only; not for end use.

Mr. FELDMAN. And they build them with their own facilities?

General BOUSHEY. I believe they do, sir, but they are also permitted, I think by law, to contract, if need be, and the services, of course, enter into joint arrangement with the NACA where, for example, the X15, which I am sure you know, the Air Force is funding, the Navy is funding, and the NACA is funding.

It is being built by a private contractor.

Mr. FELDMAN. Now, under the new proposal, the research takes place and the Advisory Board only acts in an advisory capacity. It can only recommend and the Director then becomes the head of the organization?

General BOUSHEY. Yes, sir.

Mr. FELDMAN. Now, if you have representatives on such an advisory board, those representatives would merely recommend, at the most, or help recommend. Is that not true?

General BOUSHEY. That is the way I understand the proposed law, sir.

Mr. FELDMAN. Now, the purpose of the liaison committee is to let the right hand know what the left hand is doing. Isn't that fundamentally the reason for it?

General BOUSHEY. Yes, sir.

Mr. FELDMAN. In the case of the Atomic Energy Commission, there is a specific provision requiring a military liaison committee. Are you acquainted with that fact?

General BOUSHEY. No, sir; I am not intimately acquainted with that, but I believe you are correct.

Mr. FELDMAN. That is the fact.

General BOUSHEY. Yes, sir; that is the fact.

I notice Colonel Armstrong, who works with the AEC, agreeing.

Mr. FELDMAN. The military liaison committee there knows precisely what the Atomic Energy Commission has in mind in connection with anything that the military might want, and vice versa?

General BOUSHEY. Yes, sir; we submit our need to them, and I believe vice versa. What they are doing is made known to us in the service.

Mr. FELDMAN. They also look to you for assistance in the event they need assistance in connection with any project that they may have in mind that involves the military.

General BOUSHEY. Yes, sir.

Mr. FELDMAN. That is a provision in the law and is required in the law.

Now, this new 17-man committee which would have, say, a representative of the military or 3 representatives of the military, could then only advise, and whether the advice was followed would be entirely up to the director.

Do you think that that type of requirement would satisfy the liaison requirements of the military?

General BOUSHEY. I have not given it much thought, sir, but quickly I would say it would, because the Department of Defense always has the recourse of going to the President, if something is not being accomplished that must be accomplished for the good of the Nation.

Mr. FELDMAN. Does that not take a lot of time?

General BOUSHEY. I imagine it would, sir, and it would have to be a pretty important thing.

Mr. FELDMAN. As compared with the other method, if you had your personal choice, which would you choose?

General BOUSHEY. I would prefer the method under which the NACA operates today, sir.

Mr. FELDMAN. Today?

General BOUSHEY. Yes, sir.

Mr. FELDMAN. But if they did not have any authority to do other than to kibitz, as Dr. Dryden put it yesterday, would your answer still be the same?

General BOUSHEY. You are comparing now to the NASA advisory committee, you might say, as compared to a military liaison arrangement that exists with the present-day AEC?

Mr. FELDMAN. That is right.

General BOUSHEY. I have not given that any thought. I don't know which would be better.

Mr. FELDMAN. We know from experience, plus the fact that we have had this body of experience with the Atomic Energy Commission, that that is functioning smoothly.

We don't know how this new arrangement would work under the new setup.

General BOUSHEY. You are correct. The NASA is new and the NACA as it presently exists and the AEC arrangement both work, and they both work effectively. We know how the NACA works; how it would work with the new arrangement we don't know.

Mr. FELDMAN. We do know that the Advisory Board has to meet only four times a year. It might meet, say, even 10 times a year, whereas the liaison committee between the military and the AEC under the AEC law is a constant, permanent body. They know exactly what is going on at all times.

General BOUSHEY. Your opinion is well taken.

Mr. FELDMAN. And it sifts or seeps down to the lowest level. Would your conclusion be any different in that hypothesis, assuming that is not the fact?

General BOUSHEY. Sir, I am in an area where I really cannot give an answer. I don't know enough about it.

Personally, the reason I made the remark, I thought the three services should be on the new NASA, is merely that it did not seem that 1 out of 17 was a proper proportion. Out of the $40 million that the military spends, a lot of it goes for space effort. That is my only basis for saying that.

Mr. FELDMAN. You would be in favor of the strongest kind of liaison. Is that right?

General BOUSHEY. Yes, sir; that is correct.

Mr. FELDMAN. In other words, if you had your choice you would choose the stronger of the two?

General BOUSHEY. Correct.

Mr. FELDMAN. And that which protected the military?

General BOUSHEY. Yes, sir.

Mr. FELDMAN. Incidentally, will you put that glossary that Congressman Fulton asked you to prepare into the record?

General BOUSHEY. This one, sir?

Mr. FELDMAN. Do you think that could be improved on in any way?

General BOUSHEY. Undoubtedly, sir. He said he already had a copy of it.

Mr. FELDMAN. I think he asked if it might be reworded and put in the record as part of your testimony.

The CHAIRMAN. Without objection, that will be made a part of the record.

(The material referred to follows.)

Interim Glossary

Aero-Space Terms

Air University
March 1958

Air University Documentary Research Study
(AU–282–58–RSI)
Published at
Maxwell Air Force Base, Alabama
March 1958

Personal views or opinions expressed or implied in this publication are not to be construed as carrying official sanction of the Department of the Air Force or the Air University.

Preface

This glossary of aero-space terms is published to give guidance in a specialized vocabulary that deals with space missiles, space vehicles, and the physical laws that govern them. The vocabulary involved is very rapidly developing. There are new coinages and new combinations like *destruct*, *launch pad*, and *burnout velocity;* there are also new meanings of old words. A word like *space*, for example, has acquired a meaning not previously noted when used to describe an upper region with a lower limit well within the atmosphere of the earth (see the vocabulary). Likewise, a word like *satellite* is now commonly applied to an object shown in popular magazines as resting upon a scientist's desk, gleaming with reflective paint and bristling with antennas; heretofore a satellite has had to be in orbit to be a satellite.

One thing in particular the user must understand. The data on missiles, such as *Atlas*, is from press reports. It is probably reliable, but is not official, and is offered only for general comparison.

The glossary is to be regarded as an interim affair, brought out because of the high degree of current interest in the subject of space relations. We need a broader coverage than what can now be afforded. This can be acquired, especially if the users of the glossary will send in additions and critical comments to the Editor. He is working on a more comprehensive glossary, and he welcomes widespread help.

Preface

One good way to help him is to send in a quotation that illustrates a term. Don't try to define the term yourself necessarily, although this will help; just pick out a good quotation, or concoct a sentence that will give enough context to show how you understand the term. The Editor can then compare this usage with that of other quotations.

Users of the glossary ought also to make use of a good commercial dictionary and the USAF Dictionary. Many words used in space operations are taken from aviation contexts, and as the future develops, more words and phrases are going to be introduced by Air Force people, based upon knowledge accumulated in flight through the atmosphere.

Special acknowledgements are due the following for assistance on the present interim glossary: the Commander's staff in Air University Headquarters, the Research Studies Institute, the Air University Quarterly Review, the School of Aviation Medicine, the faculty of the Weapons Course of the Air Command and Staff College, and the Ballistic System Education Division of Air University with the Ballistic Missile Division of ARDC.

WOODFORD A. HEFLIN, *Editor*

Research Studies Institute

A

AAM *(abbr)*. 'Air-to-air missile.'

ABMA *(abbr)*. 'Army Ballistic Missile Agency.'

abort, *n*. **1.** In an operational action, an instance of a rocket missile or vehicle failing to function effectively and not achieving the objective plotted for it. **2.** A rocket missile or vehicle that so fails.

In sense 1, an abort may take place at any point from the ignition action to the end of the trajectory or other objective. An abort is distinguished from a test failure (which see).

abort, v. *intr*. Of a rocket missile or vehicle: To become an abort.

absolute zero. The temperature at which all thermal motion or heat action ceases, approximately −273.16° C, −459.69° F, 0° K, and 0° R.

acquisition and tracking radar. A radar set that locks onto a strong signal and tracks the object reflecting the signal.

Aerobee, *n*. A research sounding-rocket developed by Aerojet-General Corporation. See **sounding rocket.**

The Aerobee is a two-step rocket, the first a booster rato unit, the second a liquid rocket. Its overall length with booster is 26 feet, its diameter 1.25 feet, its weight 1,655 lbs. Unguided but stablized by a tail fin, it reaches 90 miles altitude at a speed of 2,900 mph. An advanced version, the *Aerobee-Hi*, is reported as reaching 160 miles.

aeroembolism, *n*. The formation of gas bubbles (principally nitrogen) in body tissues after exposure to conditions of low atmospheric pressure, as in high-altitude flying without benefit of a pressure suit or pressurized cabin; the illness brought on by the presence of these bubbles.

aeropause, *n*. An upper region of the atmosphere in which the atmosphere ceases to function for manned or unmanned flight.

The lower limits of the aeropause vary according to the use to which the atmosphere is put, its upper limits recede as man advances in knowledge of aeromedical and aeronautical design.

aero-space, *a*. Of or pertaining to the earth's envelop of atmosphere and the space above it, the two considered as a single realm for activity in the launching, guidance, and control of ballistic missiles, earth satellites, dirigible space vehicles, and the like.

The upper limits of the aero-space realm recede upward as technology and science bring it under greater control.

AFBMD *(abbr)*. 'Air Force Ballistic Missile Division.'

AFCRC *(abbr)*. 'Air Force Cambridge Research Center.'

AFFTC *(abbr)*. 'Air Force Flight Test Center.'

AICBM *(abbr)*. 'Anti-intercontinental ballistic missile.'

aiming error. In missilry, an error that results from a miscalculation in such matters as longitude or latitude, distance, speed, re-entry deflection, or the like. Cf. **circular probable error.**

air, *n.* **1.** The mixture of gases in the atmosphere. **2.** The element that gives lift to aircraft, or offers resistance to objects that move through it. **3. a.** The region above and around the earth, including the atmosphere and the space beyond, subject to control by air or space vehicles, in contradistinction to land and sea. **b.** *Restrictive.* That part of this region that includes the atmosphere up to its effective upper limits, but not outer space. See **effective atmosphere.**

A strong trend has set in to restrict the word *air* in many contexts of sense 3 to the meaning set forth in sense 3b. This leads to considerable ambiguity in combined forms already in use, such as *air attack, air control, air force, air power, air vehicle, air warfare,* and *air weapon,* which carried broad meanings reasonably understood so long as the capability for space travel had not made it necessary to distinguish between flight through the air (i.e., the atmosphere) and flight through outer space. Space capability, however, has automatically given restricted meanings to these terms, making it necessary to avoid ambiguity by introducing changes in phraseology. See, for example, the definition of *continental air defense,* wherein the necessity is clear for using *air attack* in a restricted sense.

air-breather, *n.* A missile, like the Snark, propelled by fuel oxidized by intake from the atmosphere.

aircraft rocket. A rocket missile specially designed to be carried by, and launched from, an airplane.

Air Force Ballistic Missile Division. (AFBMD) A division of Headquarters ARDC, established as a field organization at Inglewood, California, to command and control the development of an operational intercontinental ballistic missile.

Air Force Cambridge Research Center. (AFCRC) See note.

This is an ARDC center, located at Lawrence G. Hanscom Field, Massachusetts, which conducts research and development in electronics, geophysical sciences, balloon technology, and human engineering.

Air Force Flight Test Center. (AFFTC) An ARDC center at Edwards Air Force Base: See note.

This center accomplishes functional flight tests of complete, manned aircraft weapon systems, conducts engineering evaluation flight tests of aircraft and power plants, makes static firing tests of missile power plants.

Air Force Missile Test Center. (AFMTC) A major subdivision of the Air Research and Development Command with headquarters at Patrick AF Base, Florida.

The AFMTC is responsible for the missile launching site at Cape Canaveral.

Air Force Special Weapons Center. (AFSWC) An ARDC center at Kirtland AF Base, New Mexico.

This center develops and tests atomic weapons and systems components; and evaluates personnel hazards associated with their employment.

airframe, *n. Specif.* in reference to rockets: The bodily structure of a rocket missile or rocket vehicle that supports the different systems and subsystems integral to the missile or vehicle.

The airframe includes the framework and outer skin, likewise the nose cone and combustion chambers so long as they remain attached to the vehicle.

Air Research and Development Command. (ARDC) A major air command of the USAF charged with carrying out research and develop-

ment in basic and applied science and in human engineering in order to provide for the requirements of the USAF.

air weapon. **1.** A weapon used by an air force, employed above the earth, either within the atmosphere or in outer space. **2.** *Restrictive.* Such a weapon essentially used within the confines of the atmosphere.

Use of the term *space weapon* as a differentiating term automatically gives a restrictive meaning to *air weapon* See **air,** *n*, note

albedo, *n.* The ratio of light reflecting from an unpolished surface to the light falling upon it.

This term is used esp in reference to light reflected from the moon or the planets

alcohol, *n.* Ethyl alcohol (C_2H_5OH) or methyl alcohol (CH_3OH), used with liquid oxygen as a bipropellant. See **specific impulse,** note.

Ethyl alcohol and liquid oxygen were used in the German V-2

Alpha, *n* The Explorer. So named by IGY American scientists. Also called '1958 Alpha.'

In 1957, Sputnik I was called '1957 Alpha,' Sputnik II '1957 Beta'

analogue computer. A computing machine that works on the principle of measuring, as distinguished from counting, in which the measurements obtained, as voltages, resistances, etc., are translated into desired data. See **digital computer.**

Analogue computers range from the relatively simple devices of the slide rule or airspeed indicator to complicated electrical machines used for solving mathematical problems Radar and gun directors lean heavily upon this type of computer.

anoxia, *n. Medicine.* An absence of oxygen in the blood, cells, or tissues of the body. Often confused with hypoxia (which see).

antimissile missile. An explosive missile launched to intercept and destroy another missile in flight.

apogee, *n.* **1.** That point in an elliptical orbit of an earth satellite at which the distance is greatest between the orbiting body and the earth. Cf. **aphelion,** *n.*, **perigee,** *n.* **2.** The point of greatest distance from the earth in the trajectory of a ballistic missile.

Since the orbit of an earth satellite is elliptical, its apogee (sense 1) is 180° from the perigee through the center of the earth. See **ellipse,** *n*

aphelion, *n.* That point on a planet's or comet's orbit most distant from the sun. Cf. **ellipse,** *n.*

The earth's aphelion is about 94,500,000 miles from the sun

ARDC *(abbr).* 'Air Research and Development Command.'

ARDC center. One of the several major subdivisions of ARDC directly subordinate to Headquarters Air Research and Development Command See entries on page 2 for examples of ARDC centers

Aries, *n.* *The first point of Aries,* the vernal equinox.

Army Ballistic Missile Agency. (ABMA) An agency of the US Army, with research and development facilities at Huntsville, Alabama, charged with research and development of rocket missiles and rocket vehicles.

ARPA *(abbr).* 'Advanced Research Projects Agency.'

The ARPA was established by Secretary of Defense McElroy to press the development of antimissile missiles, space vehicles, and other related technical equipment, its first director, appointed in February 1958, was R. W. Johnson, a vice president of General Electric.

artificial earth satellite. A manmade earth satellite, as distinguished from the moon. Usually called 'earth satellite.'

ASM *(abbr).* 'Air-to-surface missile.'

astrionics. The art or science of adapting electronics to space flight.

astrobiology, *n.* A branch of biology concerned with the discovery or study of life on planets.

astronaut, *n.* One concerned with flying through space, or one who navigates through space. See **astronautics,** *n.*, note.

astronautics, *n.* **1.** The art, skill, or activity of operating space vehicles. **2.** In a broader sense, the art or science of designing, building, and operating space vehicles.

Because the prefix *astro* means 'star,' this term is, or may be, considered not wholly acceptable as defined. The term *spationautics,* however, has not been widely adopted

astronomy, *n.* The science concerned with spatial bodies, their magnitudes, motions, constitution, and interrelations.

Atlas, *n.* An AF ground-to-ground ICBM developed by Convair. Also called the SM-65.

atmosphere, *n.* (atm) **1.** The body of air which surrounds the earth, defined at its outer limits by the actual presence of air particles but in such few numbers that collisions between them are so rare as to make the force of gravity the only means of keeping them associated with air particles at lower altitude. **2.** The effective atmosphere (which see).

In sense 1, the atmosphere is usually considered to consist of different stratums or spheres, the last extending to 1,000 miles or more above the earth. From one standpoint these are the troposphere, the stratosphere, and the ionosphere, from another the lower atmosphere, the middle atmosphere, and the upper atmosphere. But these same spheres, or other spheres differently conceived, may have properties that make for use of other names, as those of *chemosphere, isothermal region, ozonosphere, exosphere, ecosphere, mesosphere,* and *thermosphere.* See separate entries

Temperatures vary in the atmosphere from a standard of 58° F at sea level to 40° F at 5,000 feet, 23° F at 10,000 feet, –13° F at 20,000 feet, –39° F at 30,000 feet, –68° F at 40,000 to 100,000 feet, etc, to an estimated 4,000° F at 2,112,000 feet or 400 miles These temperatures, sometimes reported by the Rankine scale (which see), are relative to the air particles or other objects in the stratums that absorb heat. Empty space between particles are without heat.

Sonic speeds also vary with altitude—1,120 ft/sec at sea level, 1,040 ft/sec at 20,000 feet, 973–975 ft/sec in the stratosphere, 1,430 ft/sec at 400,000. Above this (75 miles), sonic speed is without practical meaning because of the rarity of air particles.

259730—58——36

atmospheric refraction. Refraction of light from a distant point by the atmosphere, caused by its passing obliquely through varying air densities.

attitude, *n.* The in-flight position of a missile or other flying body described by reference to its inclination about one or two of its three axes, the longitudinal, the horizontal, and the vertical.

auntie, *n.* Also **anti.** Slang for 'antimissile missile.'

B

B-52 Defense. An AF air-to-air missile for use in strategic air operations, in development by General Electric.

ballistic condition. A condition affecting the behavior of a missile or vehicle in flight.

Ballistic conditions include the velocity, weight, shape, and size of the missile or vehicle, likewise the density and temperature of the ambient element, and the rotation of the earth

ballistic missile. *Specif.* Any missile guided during powered flight in the upward part of its trajectory that becomes a free-falling body in the latter stages of its flight toward its target.

A ballistic missile is an assembly of a number of interconnected and interacting systems and subsystems The warhead is detonated at a predetermined target by a fuzing system, the velocity and position of the vehicle during powered flight is regulated by a guidance system so as to achieve a correct trajectory before thrust cutoff; attitude stability during powered flight is maintained through a control system, electric power is provided by an accessory power subsystem, propulsion is developed through a propulsion system, monitoring equipment is provided to furnish data from test flights, and the airframe is built to support everything in the missile. The missile, at every stage in its performance, is dependent upon a precisely calculated interaction of the systems it incorporates.

Ballistic Missiles Office. (BMO) An office of Headquarters Air Materiel Command established at Inglewood, California, so as to provide a streamlined logistics system for IRBM's and ICBM's. Cf. **AFBMD** *(abbr).*

ballistic trajectory. That part of a missile trajectory traced after the propulsive force is cut off.

bioastronautics, *n.* Astronautics considered for its effects upon animal or plant life.

biodynamics, *n.* The study of the motions of bodies and of the forces acting upon bodies in motion, or in process of changing motion, as these motions or forces affect life.

biosatellite, *n.* A satellite designed to carry an animal or plant, or a satellite that carries an animal or plant.

The word *animal* as used here includes man

biosphere, *n.* That part of the earth and its atmosphere in which animals and plants live.

bipropellant, *n.* A liquid rocket propellant that consists of a liquid fuel and a liquid oxidizer each separated from the other until introduced into the combustion chamber; also either the fuel or the oxidizer before being brought together.

bird, *n.* A figurative name for a missile, earth satellite, or other inanimate object that flies.

block house. A reinforced concrete structure, often built underground or half underground, and sometimes dome-shaped, to provide protection against blast, heat, or explosion during missile launchings or related activities

BMD *(abbr).* Air Force 'Ballistic Missile Division.' In full, AFBMD.

BMO *(abbr)* 'Ballistic Missiles Office'

boattail, *n.* The cylindrical section of a ballistic body that continually decreases in diameter toward the tail to reduce overall aerodynamic drag.

boiling, *n. Medicine.* With respect to body fluids: Profuse vaporization that occurs at 47 mm or less of mercury.

Bomarc, *n* An AF ground-to-air delta-winged missile developed by Boeing. Also called IM–99.

The missile in its new version is reported to be 47 feet in length, 18 feet in span, 4½ tons in weight, with a speed greater than mach 2, and a range of 250 miles plus Powered by solid rocket motors, it is guided by radar or by radio command An earlier version, 66 feet in length, was launched by booster rockets, at mach 1, two ramjets mounted beneath the wing took over

booster rocket. 1. A rocket motor, usually a solid rocket, that assists the normal propulsive system of a rocket or air vehicle in some phase of its trajectory or flight path. **2.** Also applied to a first-stage rocket, as in the Aerobee.

A booster rocket (sense 1) may be incorporated into a first-stage rocket to give added power at takeoff, or it may be a rato unit externally attached.

Bulldog, *n* A Navy air-to-surface rocket missile undergoing development by Martin

The Bulldog is expected to be a larger version of Bullpup

Bullpup, *n.* A Navy air-to-surface missile undergoing development by Martin.

The Bullpup, with a solid propellant, is reported to weigh 540 lbs, to have a range of 3 miles, and to be 11 feet in length

burnout, *n.* **1.** The event or action that marks the final combustion or oxidation of a fuel. **2.** The moment that this event takes place.

burnout velocity. The velocity of a rocket at the end of propellant oxidation.

C

CAF *(abbr).* 'Complete assembly for ferry.'

Cape Canaveral. A cape on the east coast of Florida, the site of Cape Canaveral Auxiliary Air Force Base, used as a laboratory for launching missiles or space vehicles.

The Air Force Missile Test Center operates the launching site

captive test. A static or hold-down test of a rocket engine or motor. Distinguished from a flight test.

carrier rocket. A rocket vehicle used to carry something, as in 'the carrier rocket of the first artificial earth satellite.'

CAS *(abbr).* 'Complete assembly for strike.'

CASF *(abbr).* 'Composite air strike force.'

celestial body. 1. A spatial body that exists in the heavens. **2.** *Restrictive.* Any such body exclusive of a manmade space vehicle.

This term (sense 1) includes the sun, the stars, planets, meteors, the moons, the manmade space vehicles It does not, however, include the earth from one point of view, but by transference, it is commonly used to include the earth The generic term that covers all celestial bodies and the earth is *spatial body*

Technically *celestial body* covers nebulae, but *celestial structure* is also applied to them The term is also generic for the terms *astronomic body, planetary body, satellite body,* and *meteoric body*

celestial guidance. The guidance of a missile or vehicle by reference to celestial bodies.

The missile is equipped with gyroscopes, telescopes, mechanically or electrically recorded navigational tables, computers, and other instruments and devices that sight stars, calculate positions, and direct the missile The Snark, for example, is equipped with celestial guidance.

celestial mechanics. That branch of mechanics concerned with mathematical development of postulates treating of the motions of celestial bodies.

celestial sphere. An imaginery sphere of infinite radius assumed for navigational purposes, the center of which coincides with the center of the earth.

The equator of this sphere s an extension of the plane of the earth's equator

center of mass. That point in a given body, or in two or more bodies that act together in respect to another body, which represents the mean position of the matter in the body or bodies.

The center of mass in the earth about which the moon revolves is not at the same point as the center of mass of the two bodies as it revolves about the sun.

central control. 1. Control exercised over an extensive and complicated system from a single center. **2.** The place from which this control is exercised. Often *capitalized* to designate a particular place, as in 'Central Control at Cape Canaveral, the electronic nerve center of all missile firings.'

The Central Control at Cape Canaveral is located several miles from the launch platform or pad.

C.G.S. *(abbr).* 'Centimeter–gram–second.'

This abbreviation designates a system in which the unit of length is the centimeter, the unit of mass is the gram, and the unit of time is the mean solar second Used, for example, in defining the constant of gravitation

chemosphere, *n.* A stratum of the atmosphere considered to begin at approximately 20 miles and to extend to 50 miles above the earth, marked for its photochemical activity.

By some meteorologists, the chemosphere is considered to be an extension of the stratosphere

circular probable error. (CEP) In missilry, a probable error used as a factor in determining the probable damage to a target expressed in terms of the radius of a circle which would include half of the missile strikes of missiles aimed at the center of the circle.

cislunar, *a* Of or pertaining to space between the earth and the orbit of the moon, or to a sphere of space centered on the earth with a radius

equal to the distance between the earth and the moon.

closest approach. The place or time at which two planets are nearest to each other as they orbit about the sun.

cluster, *n. Specif.* Two or more solid rocket motors bound together so as to function as one propulsive unit.

coasting flight. The flight of a rocket missile or vehicle between burnout or thrust cutoff of one stage and ignition of another, or between burnout and summit altitude or maximum range (if constrained to move along a straight line).

command destruct signal. A radio signal that detonates an explosive in a rocket missile or vehicle so as to destroy it.

composite, *a.* Of a force: **a.** Having or operating different kinds of equipment, as bomber aircraft and ballistic missiles. **b.** Made up of dissimilar elements, as of two or more services.

ConAD *(abbr).* 'Continental air defense.' Cf. **NorAD** *(abbr).*

console, *n.* A basic instrument control panel usually mounted on a large tablelike piece of equipment with a slanting top, and used as a 'go-no-go' control for the launch of a rocket or for its destruction.

constant of gravitation. The acceleration that results from the attraction of a unit of mass at unit distance, determined by Heyl in 1942 to be $6.673 \times 10 \times 10^{-8}$ in C.G.S. units. See **C.G.S.** *(abbr).*

constellation, *n.* **1.** Any one of the arbitrary groups of fixed stars—some 90 now recognized. **2.** A division of the heavens in terms of any one of these groups.

continental air defense. A coordinated defense of the continental United States against air or missile attack. Cf. **air,** *n.*, note.

The defense is coordinated as among the ground, sea, and air forces, and civil defense authorities

control, *n. Specif.* **1.** The power exercised mechanically, electrically, or electronically over a rocket vehicle or rocket missile during the period of its launching and usually during a limited or extended period of its flight; the exercise of this power. **2.** Attrib., as in *control panel, control room,* etc.

The exercise of control is usually a coordinated procedure involving the use of many technicians

control system. A system in a ballistic or guided missile that serves to maintain attitude stability during powered flight and to correct deflections caused by gusts or other disturbances.

Although distinguished from the guidance system, and the responsibility of a separate research and development group, the control system uses certain devices in common with the guidance system, such as jet vanes and swiveling engines.

Cooke Air Force Base. An AF base associated with Camp Cooke, Lampoc, California, used for training missile units and being developed as a missile test launching site.

coriolis force. A deflecting force exerted by the rotation of the earth upon any object in motion, diverting the object to the right of velocity in the northern hemisphere, and to the left in the southern.

This term is named after a French mathematician who detected it, Gaspard Gustave de Coriolis (1792–1843).

Corporal, *n.* An Army ground-to-ground liquid rocket missile developed by Firestone.

This missile is said to be 40 feet long or longer, weighing 6 tons, with a speed of mach 3 and a range of 100 miles It is an outgrowth of the Wac Corporal (which see).

Corvus, *n.* A Navy air-to-surface solid propellant rocket missile undergoing development by Temco.

cosmic ray. Any ray of high penetrative power produced, according to tentatively accepted theory, by transmutations of atoms in interstellar space.

These rays bombard the earth and other objects n space, in the atmosphere they cause ionization

cosmos, *n.* The totality of the observed and postulated physical whole, conceived as an orderly and harmonious system.

The Greek word *kosmos* means order or harmony.

count-down, *n.* In the final make-ready for the launch of a rocket missile or vehicle, the action of checking each system or subsystem one after the other, using a count, e.g., 'T minus 60 minutes,' in inverse numerical order so that the count narrows down at the end to 4-3-2-1-*zero, minus 1, minus 2,* etc, during which time 'the button is pressed,' i.e., the propellant is ignited.

The count-down normally takes, in the present state of the art, considerable time to effect—sometimes several hours.

D

Dart, *n.* An Army ground-to-ground solid rocket antitank missile made by Utica-Bend of Studebaker.

The Dart is said to be 5 feet long, with a speed of 600 mph and a range of 2 miles

declination, *n.* In astronomy and celestial navigation, the angular distance of a celestial body from the celestial equator measured through 90° and named 'north' or 'south' as the body is north or south of the celestial equator measured on an hour circle.

destruct, *n.* The deliberate action of detonating or otherwise destroying a rocket missile or vehicle after it has been launched, but before it has completed its course. Said of friendly missiles esp. during test flights.

Destructs are executed when the missile gets off its plotted course or functions in a way as to become a hazard

deterrent, *n.* That which deters, esp a force in-being recognized by an aggressor nation to have such retaliatory power as to make the cost of aggression unacceptable. Said of a bomber force or a missile force. Hence, **deterrent force.**

device, *n* (dv) A mechanism that works to serve a particular purpose. Used esp. as the second element in combinations, as in *rocket device, satellite device,* or *atomic device.*

Diamond Back. A Navy air-to-air missile, still in the research and development stage under Navy Ordnance.

digital computer. A computer that works on the principle of counting, as distinguished from measuring. See **analogue computer.**

Digital computers make up a family of computers, ranging from the abacus to the business-office adding machine, to electrical relay computers as used in telephone exchanges, to the complex electronic calculators, such as Eniac Electronic computers use either a decimal or binary system of notations

Doppler, *n* [Christian *Doppler* (1803–53), a German mathematician] Used attrib. or in combination: See note

Doppler drift, the drift of a missile as determined through use of Doppler's principle by means of radar, *Doppler effect,* the apparent change in the frequency of vibrations, as of sound, light, or radar, when the observed and observer are in relative motion to one another; *Doppler's principle,* a principle of physics that, as the distance between a source of constant vibrations and an observer diminishes or increases, the frequencies appear to be greater or less, *Doppler radar,* a radar that makes use of the fact that the return signal shifts in carrier frequency by an amount proportional to the velocity with which an object, such as a missile, is moving away from, or toward, the radar, measurement of the shift being itself a measurement of the velocity of the moving object, *Doppler shift* a shift of a luminous body's lines in a spectrum toward the red indicating an increase in distance

Dove, *n.* A Navy air-to-surface solid propellant rocket missile developed by Eastman.

According to press reports, the Dove homes upon its target by radar

dry-fuel rocket. A rocket that uses a mixture of fast-burning power. Used esp. as a booster rocket.

dry run. A practice exercise or rehearsal esp. observed in preparation for a rocket launching, usually several times.

dry weight. The weight of a rocket vehicle without its fuel. Cf. **takeoff weight.**

This term appropriate esp for liquid rockets, is sometimes considered to include the payload

Duck, *n* An AF air-to-air missile still in research and development by Fairchild.

E

earth, *n* **1.** The planet we inhabit including its atmosphere. **2.** This planet without its atmosphere, 7,900 miles in diameter at the poles, 7,927 at the equator, 3,959 miles mean radius.

earth satellite. A body that orbits about the earth; *specif.,* such a body placed in orbit by man, otherwise called an 'artificial earth satellite.'

ebullism, *n. Medicine.* The formation of water vapor bubbles in the tissues brought on by boiling of body fluids.

eccentric, *a* Of an orbit· Deviating from the line of a circle so as to form an ellipse. Hence, **eccentricity,** *n.*, the state or degree of being eccentric, expressed by the difference of greatest and least distances between the two centers of mass, divided by the sum of the greatest and least distances

The eccentricity of the earth's orbit is 0 016751

ecliptic, *n.* That great circle on the celestial sphere which describes the apparent path of the sun in the course of the year.

The plane of the ecliptic is the plane in which the center of mass of the earth and moon revolves about the sun It is inclined to the plane of the equator at an angle of about 23°27′

ecosphere, *n* A layer in a sphere inhabited by living organisms or suitable for the life of such organisms. **a.** A layer of space about the sun extending from, and including, Venus through Mars **b.** The biosphere of the earth, esp that part of the troposphere extending to about 13,000 feet

effective atmosphere. That part of the atmosphere which effectively influences a particular process or motion, its outer limits varying according to the terms of the process or motion considered. Cf **sensible atmosphere.**

For example, an earth satellite orbiting at 250 miles altitude remains within the ionosphere, but because the air particles are so rare at this altitude as to cause no appreciable friction or deflection, the satellite may be considered to be outside the effective atmosphere For movement of space vehicles the effective atmosphere ends at about 120 miles altitude

ellipse, *n.* A plane curve described about two fixed points (the foci) so that the sum of the distances between any point on the curve and the foci is equal to the sum of the distances between any other point on the curve and the foci.

In the orbit of a planet or satellite, one of the fixed points is the center of the primary body (the sun or the earth) so that the point of greatest nearness in the orbit is 180° from the point of greatest distance through the major axis of the ellipse

engineer, *n.* (engr) A person professionally competent to design, construct, or operate something, esp. as used in such phrases as 'missile engineer,' 'rocket engineer,' or 'scientists and engineers.'

A scientist is one learned in a science or sciences, accustomed and qualified to do theoretical and experimental research in an effort to discover new principles or new knowledge, an engineer is one trained to design or build a structure or machine in accord with principles or knowledge discovered or developed by the scientist

escape velocity. A property of a spatial body expressed in terms of the speed in an outward direction that a molecule, rocket, or other body must move in order for it to escape the gravitational attraction of the spatial body.

The earth's escape velocity is not quite 7 statute miles per second, the moon's about 1 5 statute miles per second

exhaust velocity. The velocity of gases that exhaust through the nozzle of a rocket engine or motor relative to the nozzle. See **thrust,** *n.*

The exhaust velocity may be obtained by multiplying the specific impulse by gravity 32 2 See **specific impulse.**

exosphere, *n.* The outermost fringe or layer of the atmosphere, where collisions between molecular particles are so rare that only the force of gravity will return escaping molecules to the upper atmosphere.

exospheric, *a.* Of or pertaining to the exosphere.

exotic fuel. A fuel considered to be unusual, as liquid hydrogen with a fluorine oxidizer.

exploratory rocket. A rocket built and equipped to explore the upper atmosphere or outer space.

Explorer, *n.* **1.** The first American earth satellite to reach and remain in orbit, launched at 2248 hours (EST), 31 January 1958. Also called 'Alpha' or '1958 Alpha.' **2.** Also applied generically to any other American earth satellite.

The Explorer, with an overall earth weight of 30.8 pounds, consists of an outer skin (that of the last rocket stage) 80 inches long, 6 inches in diameter, which contains a 30-inch long steel shell weighing 7.5 pounds, inside of which is an 11-pound package of complex gauges, meters, wires and miniradio transmitters. The satellite does not tumble as Sputnik II is reported to do, but spins on its longitudinal axis at 700 rpm. It completes its orbit once every 113 or 114 minutes, its apogee 1,600 or more miles from the earth, its perigee 230 miles. It orbits in a plane at 35° to the earth's equator at a velocity of about 18,000 mph.

F

F-108. A projected fighter interceptor expected to develop speeds of mach 3.

Falcon, *n.* An AF air-to-air rocket missile developed by Hughes for use in North American air defense, as with the F-89, F-102, or F-106.

According to press reports, the Falcon's length is 6½', its diameter 1½', its weight 100 lbs, its speed mach 2, and its range 5 miles. It is an aircraft rocket, self-guided by radar (the GAR-1A) or by infrared (the GAR-2A).

fall-away section. Any section of a rocket vehicle that is cast off and falls away from the vehicle during flight.

Farside rocket. A four-stage solid research rocket launched from an unmanned plastic balloon as a part of AF Project Farside.

The rocket, suspended nose upward from the balloon, is fired at an altitude of 20 miles. It tears through the balloon to climb to 4,000 miles.

fps *(abbr).* 'Feet per second.' Cf. **ft/sec** *(abbr).*

free-flight trajectory. That part of a ballistic missile's trajectory that begins with thrust cutoff and ends at re-entry. See **re-entry trajectory.**

free radical. An atom or group of atoms broken away from a stable compound by application of external energy, and, although containing unpaired electrons, remaining free for transitory or longer periods.

Interest centers on three radicals, atomic hydrogen (H), atomic nitrogen (N), and the imine radical (NH). In their free state, they are highly active, combining with each other or with other substances to form other stable molecules, and yielding in the process energies well in excess of those available from conventional chemical fuels. Their use in propulsive systems, now theoretical, depends upon their being isolated and available in bulk, either in pure form or dissolved in a desired concentration in another fuel.

FTCC *(abbr).* 'Flight Test Coordinating Committee.'

This committee is composed of USAF and NACA representatives and a Navy liaison officer to monitor the testing of X-15

ft/sec *(abbr).* 'Feet per second.' Cf. **fps** *(abbr).*

fuel, *n.* Any substance used to produce heat or a rapid expansion of gases esp. by burning; *specif.*, any such substance used to power a rocket motor or rocket engine.

Fuel is distinguished from a propellant (which see) The term is broad enough to include atomic fuels, but in the present state of the art, atomic fuels are considered from 5 to 20 years away for rocket motors.

G

galaxy, *n.* **1.** *Capitalized.* The group of several billion suns, star clusters, nebulae, etc., to which the earth's sun belongs. Also called the Milky Way. **2.** Any of several similar groups of stars forming isolated units in the universe.

The Galaxy (sense 1) is generally considered by astronomers to be shaped like a great disk of stars irregularly dispersed in clusters Its diameter is 30,000 parsecs, its thickness 1,000 to 2,000 parsecs except at the center, where it is 5,000 parsecs or more Outside the central plane other classes of objects are dispersed in spheroidal distribution extending to 5,000 parsecs beyond the central periphery and 10,000 parsecs distant from the galactic plane The spherial diameter of the globular clusters surrounding the center is 30,000 parsecs

The earth's sun is from 8,000 to 10,000 parsecs from the central part of the disk, with a rotational velocity about the central mass of 150 miles per second, taking 200 million years to complete one revolution

GALCIT *(abbr)* 'Guggenheim Aeronautical Laboratory of the California Institute of Technology.'

GAM *(abbr).* 'Guided aircraft missile.'

gantry, *n.* Short for 'gantry crane' or 'gantry scaffold.'

gantry crane. A large crane mounted on a platform that runs back and forth on parallel tracks.

gantry scaffold. A massive scaffolding structure mounted on a bridge or platform supported by a pair of towers or trestles that run back and forth on parallel tracks, used to service a large rocket as the rocket rests on its launching pad.

This structure is a latticed arrangement of girders, tubing, platforms, cranes, elevators, instruments, wiring, floodlights, cables, and ladders—all used to attend the rocket At Cape Canaveral, one of the gantries stands 150 feet high

gapa *(abbr).* 'Ground-to-air pilotless aircraft.'

gasoline, *n.* (gas) A hydrocarbon fuel used as a bipropellant with liquid oxygen. See **specific impulse,** note.

Genie, *n.* An AF air-to-air rocket missile for use in air defense, developed by Douglas.

The Genie uses a solid propellant and carries a nuclear warhead It is also known as the MB-1

geophysical constant. A quantity that expresses a fixed value for a law or magnitude that applies to the physics of the earth.

The constant of gravitation and the constant of nutation are examples of a geophysical constant

gimbaled motor. A rocket motor mounted on a gimbal, i.e., on a contrivance having two mutually perpendicular and intersecting axes

of rotation, so as to obtain pitching and yawing correction moments.

GM *(abbr)* 'Guided missile.'

Goose, *n* An AF air-to-air turbojet missile developed by Fairchild.

According to press reports, the Goose is guided by radio command It is also known as the SM-73

grain, *n*. The body of a solid propellant used in a rocket, fashioned to a particular size and shape so as to burn smoothly without severe surges or detonations

A grain may be very long (40 or 50 inches, for example), shaped to fit the requirements of the rocket, and referred to by its shape, as in *tubular grain, cruciform grain, triform grain*, etc

gravireceptor, *n*. *Medicine*. A nerve ending that responds to the mechanical stimulation of gravity.

gravisphere, *n*. The spherical extent in which the force of a given celestial body's gravity is predominant.

Green Room. *Specif*. A room of the Cape Canaveral Central Control that serves as the command center.

guidance system. One of the systems in a ballistic missile that puts the missile on a desired trajectory at a desired velocity prior to thrust cutoff, or a system in a guided missile that establishes the desired path from launch to target. See **control system,** note.

guided aircraft missile. (GAM) A guided missile launched, or designed for launching, from an aircraft.

guided missile. (GM) **1.** A missile directed to its target while in flight or motion, either by a preset or self-reacting device within the missile or by radio command outside the missile. **2.** *Restrictive*. Such a missile without wings to support it

This term is sometimes considered synonymous with 'pilotless aircraft' when the missile is supported by wings The two terms, however, suggest two different points of view, although applied to the same object The guided missile is a missile, the pilotless aircraft is a vehicle

H

hardware, *n*. Finished pieces of equipment or component parts that constitute or go to make up an operating machine or device such as a missile or vehicle.

In a missile, the hardware covers the airframe, the metalic or ceramic parts of the motor, and the instruments It does not include the fuel The term is often used to differentiate equipment and parts in their physical state from their status on the drawing board

Hawk, *n*. An Army ground-to-air missile developed by Raytheon.

This missile is said to be 16 feet long, 200 pounds in weight, with a speed of mach 2 plus, and a range of 15 miles plus Powered by a solid rocket, it is guided by radio command

heat of vaporization. The heat absorbed by a liquid when it vaporizes; the quantity of heat required at a given temperature to convert a unit mass of liquid into vapor.

heliocentric, *a.* Measured from the center of the sun; related to, or having, the sun as a center.

Hidyne, *n.* Also spelled **Hydyne.** A popular name for the hydrazone propellant of the Jupiter-C first-stage rocket.

This term is a coinage, *Hi* plus *dyne.*
Hidyne is reported to have boosted the standard Redstone burning time and burnout velocity by 12 percent.

Honest John. An Army ground-to-ground solid rocket artillery projectile developed by Douglas.

This missile is reported to be 27 feet long, 2½ feet in diameter, weighing 3 tons, with a range of 30 miles. It is guided by the amount of its thrust and by the direction of its launch.

human engineering. The art or science of designing, building, or equipping an aircraft or space vehicle to the anthropometric, physiological, or psychological requirements of a person.

hydrazine, *n.* A liquid base, NH_2NH_2, or one of the organic bases derived from it, as phenylhydrazine. Used as a liquid propellant.

hydrazone, *n.* An exotic fuel used in the first stage of Jupiter-C, formed by the action of hydrazine or one of its derivatives on a compound containing the carbonyl group, CO.

hypersonic, *a.* Of or pertaining to the speed of an object moving at mach 5 or greater relative to surrounding fluid.

hypoxia, *n. Medicine.* Oxygen deficiency in the blood, cells, or tissues of the body in such degree as to cause psychological and physiological disturbances.

Hypoxia may result from a scarcity of oxygen in the air being breathed, or from an inability of the body tissues to absorb oxygen under conditions of low barometric pressure In the latter case, water vapors from body fluids increase in the sacs of the lungs, crowding out the oxygen.

I

ICBM *(abbr).* 'Intercontinental ballistic missile.'

IGY *(abbr).* 'International Geophysical Year.'

IGY satellite. One or other of the artificial earth satellites developed for purposes of the International Geophysical Year (which see).

One of these satellites is a 20-inch sphere, with a thin magnesium skin coated with a highly polished silicon monoxide, designed to measure the Lyman-Alpha radiation in the outer ultraviolet band of sunlight, and to transmit its measurements by means of a miniature transmitter. Another is a 13-inch sphere designed to carry an inflatable subsatellite.

IM *(abbr).* 'Interceptor missile.'

inclination, *n.* The angle between one line and another or one plane and another, as the angle between the plane of the moon's orbit and the ecliptic.

inertial force. The force produced by the reaction of a body to an accelerating force, equal in magnitude and opposite in direction to the accelerating force.

Inertial force endures only so long as the accelerating force endures

inertial guidance. A kind of guidance for a missile

or the like, effected by means of mechanisms that automatically adjust the missile after launching to follow a given flight path, the mechanisms measuring inertial forces during periods of acceleration, integrating the data obtained with already-known position and velocity, then signaling the controls to effect the desired direction, altitude, etc.

inhibitor, *n.* Anything that inhibits; *specif.,* a substance bonded, taped, or dip-dried onto a solid propellant to restrict the burning surface and to give direction to the burning process.

intergalactic space. That part of space conceived as having its lower limit at the upper limit of interstellar space, and extending to the limits of space. See **galaxy,** *n.,* **space,** *n.*

Like the term *interstellar space,* this term is defined from an earthbound standpoint.

intermediate range ballistic missile. (IRBM) A ballistic missile with a range above 200 miles but less than 1,500 miles.

The limitations of range as shown are subject to change as new concepts of weapons employment are entertained.

International Geophysical Year. (IGY) See note.

The IGY, beginning 1 Jul 1957 and ending 31 Dec 1958, is a period scheduled by the world's scientists for a concerted and cooperative effort to advance scientific knowledge of the world, esp. in respect to cosmic rays, meteorology, latitude and longitude determinations, solar activity, geomagnatism, glaciology, oceanography, seismology, ionospheric physics, aurora, and gravity measurements Some 55 nations support the program, the US Congress appropriating $39 million, and the National Academy of Sciences undertaking to plan, direct, and execute the US program Prior to the IGY, preliminary work had been done by different scientific groups to provide facilities and bases from which to carry out the program.

interplanetary space. That part of space conceived, from the standpoint of the earth, to have its lower limit at the upper limit of translunar space, and extending to beyond the limits of the solar system, some several billion miles.

This term is one of distance from the earth, not one of planetary influence.

interstellar space. That part of space conceived as having its lower limit at the upper limit of interplanterary space, and extending to the lower limits of intergalactic space.

This term, as defined, is from the standpoint of an observer on the earth From the standpoint of a detached observer, it is that part of space within the Galaxy (which see).

IOC *(abbr).* 'Initial operational capability.'

ion, *n.* An electrically charged atom or group of atoms. See next.

A positively charged ion is an atom or group of atoms with a deficiency of electrons; a negatively charged ion is an atom or group of atoms with an added electron.

ion engine. A projected species of reaction engine in which thrust is to be obtained from a stream of ionized atomic particles supplied by atomic fission, atomic fusion, or solar energy. Cf **photon engine.**

This engine, designed for interplanetary travel in space where air particles offer no resistance to motion, is projected to have relatively low thrust but sufficient to build up to speeds of 100,000 mph.

ionize, *v. tr.* To make an *atom* or *molecule* of a gaseous element, such as a *particle* of air, lose an electron, as by X ray bombardment, and thus be converted into a positive ion, the freed electron then attaching itself to another molecule to form a negative ion.

ionosphere, *n.* An outer stratum of the atmosphere consisting of layers of ionized air particles.

As conceived by some meteorologists, the ionosphere begins at approximately 25 miles above the earth, by others at approximately 50 miles It varies in height with the season of the year and the time of day By some, it is considered to extend to the outermost fringe of the atmosphere beyond 1,000 miles, by others, it is considered to be bounded at its upper limits by the exosphere, or by a sphere called the mesosphere. It reflects certain radio waves and reaches temperatures of several thousand degrees It is divided into layers, the *D layer, E layer, F layer,* each defined in the *USAF Dictionary.*

IRBM *(abbr).* 'Intermediate range ballistic missile.'

isothermal region. The stratosphere considered as a region of uniform temperature. See **atmosphere,** *n*, note.

J – K

Jet Propulsion Laboratory. (JPL) A laboratory in the Guggenheim Aeronautical Laboratory of the California Institute of Technology.

JPL, organized in 1936, conducted research and development on jet propulsion for the armed services. Its first leader was Dr. Theodor von Karmán.

JPL *(abbr).* 'Jet Propulsion Laboratory.'

Jupiter, *n.* An Army ground-to-ground IRBM, with a first-stage liquid-rocket engine, developed by Chrysler.

This missile, as distinguished from the research rocket Jupiter-C, is 60 feet long, 8 feet in its maximum diameter, and has a range of 1,500 miles, a speed in excess of mach 1. Its original first-stage rocket was that of the Redstone missile. It has an inertial guidance system. See next.

Jupiter-C, *n.* The four-stage Army carrier rocket that first successfully launched an American manmade satellite, Explorer, into orbit at 2248 hours (EST), 31 January 1958.

The Jupiter-C, 70 feet long, is a research version of the IRBM Jupiter In the launching of Explorer, the first stage consisted of a liquid rocket using a hydrazone exotic fuel, two other stages used clusters of solid propellants, the fourth stage consisted of a single rocket motor

Kelvin scale. (° K) [After the first Baron *Kelvin* (1824–1907), English mathematical physicist and inventor.] A temperature scale that uses centigrade degrees, but makes the zero degree signify absolute zero.

Water freezes at 273.16° K, boils at 373 16° K. Cf. **Rankine scale.**

Kepler's laws. The three laws of planterary motion discovered by Kepler (1571–1630) that explain the movements of planets in terms of the Copernican concept.

These laws are 1 The orbit of every planet about the sun is an ellipse, the sun occupying one focus 2 A line from each planet to the sun sweeps over equal areas in equal times 3 The squares of the times required for the different planets to complete their orbits are proportional to the cubes of their mean distances from the sun.

kill, *n.* **1.** An act or instance of destroying an enemy aircraft or missile in midair. **2.** The thing destroyed.

L

Lacrosse, *n.* An Army solid rocket ground-to-ground missile, produced by Martin.

This missile is reported as 20 feet long, 9 feet in span, and a range of 20 miles It is guided by radio command by a forward observer

Laika, *n.* The name of the female dog carried as a passenger in Sputnik II.

Laika, of the Husky breed, approximately 45 pounds in weight, about 20 inches high, survived alive in the satellite from the 3rd to the 10th or 11th of November 1957. The Russians announced her alive on the 10th, dead on the 11th.

launch, *n* The procedures or action taken in launching a rocket missile or vehicle; the resultant event of this action See **vertical launch**

A launch begins when the missile or vehicle moves upward off the launcher upon ignition of the propellant, and normally ends when the missile or vehicle has achieved a velocity at which it responds to normal control through the guidance system

launch, *v. tr.* To send forth under its own power a *rocket vehicle, robot bomb,* or the like from a launching pad, rack, ramp, or other device or installation; also to rocket a *satellite* or *test sphere* upward.

launching pad. Same as 'launch pad.'

launch pad. 1. The base on which a positioned rocket missile or vehicle rests ready for launching. Usually called the 'pad.' **2.** Also applied to the site for a launch.

In sense 1, the launch pad for an uprighted missile or vehicle is usually of steel and concrete Sense 2, reported as common, is somewhat inexact usage

launch point. The point at which a ballistic missile or other rocket vehicle is launched.

light, *n.* A radiant energy that stimulates the organs of sight to perform their function, consisting, according to modern theory, of quanta transmitted at about 186,000 miles a second; by extension, a related radiant energy, such as infrared, that does not affect the retina, but otherwise acts like the same energy.

light year. The distance over which light can travel in the period of one year's time—some 6,000,000,000,000 miles, i.e., 6,000 billion miles.

liquid oxygen. Oxygen supercooled and kept under pressure so that its physical state is liquid. Used as an oxidizer in a liquid-fuel rocket.

Liquid oxygen, supercooled to as low as −297° F and kept under a constant pressure for use in a rocket, is highly explosive and requires special handling It boils at −297° F at atmospheric pressure, has a specific gravity of 1 14, and a heat of vaporization of 91 6 BTU per pound It is noncorrosive and nontoxic, but cannot be stored for any great length of time because of rapid evaporation It is usually produced close to the place where used Cf **alcohol,** *n.*, **specific impulse.**

liquid propellant. 1. A rocket propellant that consists either of a mixture of two or more liquids (a fuel, oxidizer, and sometimes an additive) or of a liquid chemical compound that provides its

own fuel and oxidizer 2. Also any one of the liquid ingredients that are to go into the mixture, i.e., the fuel, the oxidizer, or the additive, separately.

liquid rocket. 1. A rocket that uses liquid fuel **2.** Short for 'liquid rocket propellant.'

Little John. An Army ground-to-ground solid rocket artillery projectile developed by Douglas.

This missile, reported to be 12 feet long, 1 foot in diameter, with a range of 15 miles, is a short version of Honest John, developed esp for airlift

long-range, *a* or *attrib* (LR) Of a missile: Having a range greater than 1,500 miles. Used esp. in phrase *long-range ballistic missile*

The limitations of this definition are subject to change as new concepts of weapons employment are entertained Cf **intermediate range ballistic missile**

LOX *(abbr)* 'Liquid oxygen explosive.'

This abbreviation is not used for 'liquid oxygen' It is, essentially a commercial term applied to an explosive made up of liquid oxygen

lunar space. Space near the moon. Cf. **terrestrial space, translunar space.**

The gravitational attraction of the moon is predominant n lunar space

M

mach, *n.* [After Ernst *Mach* (1838-1916), Austrian physicist] A unit of speed measurement for a moving object equal to the speed of sound in the medium in which the object moves

Thus, *mach 5* is a speed equal to one-half the speed of sound in the medium, *mach 1* is a speed equal to that of sound in the medium Cf **remote velocity, speed of sound.** At transonic speeds, a body may have a speed less than mach 1 at the same time that local points on the body have speeds greater than mach 1

Mach speed has no meaning in an element that does not conduct sound See **atmosphere,** *n*, note

manned vehicle. *Specif.* An air or space vehicle that carries a person or crew. Distinguished from a pilotless aircraft, an unmanned earth satellite, a ballistic missile, or the like.

mass, *n* A measure of the quantity of matter in a body, being determined by comparing the resultant changes in velocities when the body impinges upon a standard body.

The unit for determining mass in the US is a piece of platinum kept in Washington, D C, by the National Bureau of Standards Mass differs from weight in that the weight of this piece of platinum is the attraction of the earth's force of gravity upon it In Washington, the mass and weight have equivalent values, at other points the mass remains the same, the weight, however, varies with latitude and elevation

mass ratio. The ratio of one mass to another; *specif.*, the ratio between the initial mass of a full vehicle (takeoff mass) and the final mass of the vehicle or payload (remaining mass)

For example, in the V-2 the mass of the rocket was 3 tons, the payload 1 ton, the fuel 8 tons Takeoff mass was 12 tons, remaining mass is 3+1 or 4 tons The mass ratio is 3 to 1

Matador, *n* An AF winged guided missile, surface-to-surface, developed by Martin Also called the TM-61.

The Matador, 40 feet long, 29 feet in span, with a weight of 7 tons, s propelled by a short-lived turbojet

engine (the Allison J33-A-37) with an assist from a rato unit An air-breather, it has a speed of 650 mph, a range of 500 miles or more, and a radar guidance system Now considered obsolete

Matador Mace. An AF ground-to-ground winged guided missile, similar to the Matador, developed by Martin Also called the TM-76A.

This missile, provided with an inertial guidance system and more range than the Matador, is propelled by a turbojet engine with a rato assist

mechanical border. *Specif.* That layer in the atmosphere where air resistance and friction become negligible (from 120 to 140 miles altitude). See **effective atmosphere.**

mechanoreceptor, *n. Medicine.* A nerve ending that reacts to mechanical stimuli, as touch, tension, and acceleration.

mesosphere, *n.* **1.** In the nomenclature of Chapman, a stratum of atmosphere sometimes called the chemosphere. **2.** In the nomenclature of Wares, a stratum that extends approximately from 250 to 600 miles, lying between the ionosphere and the exosphere.

In sense 2, the mesosphere s the region of sunlight auroras

meteor, *n.* A transient celestial body, natural in origin, that enters the earth's atmosphere with great velocity; also recently applied to such a body encountered or existent outside the atmosphere.

A meteor, incandescent with heat generated by friction with the air, can be mistaken for a ballistic missile.

meteoric particle. A particle of matter from a meteor; a small meteor.

mini *(prefix).* A contraction of 'miniature' used in combination, as in *minicomponent, miniradio, minitransistor;* also a contraction of the words thus made, as in *minitrack,* i.e., a minitransmitter track. See following entries.

miniature, *n.* Used attrib. in reference to equipment, such as gimbals, gyroscopes, computers, etc., made small to fit into confined spaces, as within an earth satellite or rocket missile.

miniaturize, *v. tr.* To make a functioning miniature of a *part* or *instrument.* Said of telemetering instruments or parts used in an earth satellite or missile, where room is at a premium.

Hence, **miniaturized,** *a.*, **miniaturization,** *n.*

minitrack, *n* **1.** The track of a minature transmitting set emitting telemeter-type signals. **2.** Short for 'minitrack radio.' Used attrib., as in *minitrack chain, minitrack picket.*

minitrack radio. A radio receiving set that tracks an object equipped with a miniature transmitter emitting telemeter-type signals. Used, for example, in tracking earth satellites.

missile, *n.* **1.** Any weapon object designed to be thrown at, dropped upon, projected toward, or self-propelled through space to, a target. **2.** *Specif.* A guided or ballistic missile. Often attrib., as in *missile base, missile force, missile*

25973 O—58——37

guidance, missile research, missile warhead. **3.** Short for 'missile vehicle.'

missileman, *n* A person who works on or handles a missile; *specif.*, an airman or officer in a missile unit.

missile range. A marked-off course or area over which test missiles are flown under observation. Also called 'missile test range.'

The missile range for Cape Canaveral extends out into the Caribbean and South Atlantic some 5,000 miles

missile unit. A military unit made up of persons with the skills required to service, make ready, or launch guided or ballistic missiles, or to train others to do so.

missilry, *n.* The art or science of designing, de-developing, building, launching, directing, and sometimes guiding a rocket missile; any phase or aspect of this art or science.

monopropellant, *n.* A rocket propellant, esp. a liquid propellant, in which the fuel and oxidizer make up a single substance before injection into the combustion chamber.

A monopropellant may be a mixture of compounds, such as hydrogen peroxide and alcohol, or a compound in itself, such as nitromethane The term is normally applied to liquid monopropellants rather than to solid propellants, to distinguish them from the liquid bipropellants

moon, *n.* **1.** The natural celestial body that orbits as a satellite about the earth. Called 'the moon.' **2.** Also applied generically to any one of the manmade earth satellites, or to a satellite of a planet other than the earth.

In sense 1, the moon has a diameter of 2,160 miles, a mean distance from the earth of about 238,857 miles, a mass about 1/81st that of the earth, and a volume of about 1/49th Its mean orbital velocity is about 2,285 statute mph, its apogee 252,710 miles, its perigee 221,463 miles

moon rocket. A rocket vehicle used to carry a payload to the moon, either to circle it and return to earth, or to land upon it.

multistage rocket. A rocket having two or more thrust-producing units, each used for a different stage of the rocket's flight.

N

NACA *(abbr).* 'National Advisory Committee for Aeronautics'

Created by act of Congress 3 Mar 1915. NACA has 17 members, 2 of them from the AF Its 3 principal laboratories are the Langley Aeronautical Laboratory at Langley AFB, the Ames Aeronautical Laboratory at Moffett Field, and the Lewis Flight Propulsion Laboratory at Cleveland

Navaho, *n.* A long-range air-breathing guided missile developed by North American. Also called the SM-64.

This intercontinental missile is propelled by two ramjet engines, except that it is normally rocket-boosted to an altitude of 50,000 or more feet

Neptune, *n.* An early name for the Viking when it was in the development stage.

Nike, *n.* [Pronounced *Nigh-kee*] Any of three different ground-to-air missiles developed, or being

developed, by Douglas and Western Electric for the Army

The *Nike-Ajax*, a liquid rocket missile with a solid booster, 20 feet long, 5 feet in span, weighing 1,000 pounds, with a speed of mach 2, a range of 30 miles is guided by radio command The *Nike-Hercules*, a solid rocket missile with a cluster of boosters, is said to be 27 feet long, 2 feet in diameter, with a weight of 2,000 pounds, a speed of mach 3, a range of 70 miles It is guided by radar or radio command The *Nike-Zeus*, under development, will probably have a range of 100 miles

node, *n.* Either of the two points where the orbit of an orbiting body intersects the plane of the orbit of its primary. Cf. **ecliptic,** *n*

NorAD *(abbr).* 'North American air defense.'

North American air defense. (NorAD) A coordinated defense of the North American continent against air or missile attack. Cf **air,** *n*, note

The defense is coordinated as between American and Canadian services with full use of early-warning radar

nose cone. A cone-shaped shield that fits over, or is, the nose of a rocket vehicle or rocket missile, built to withstand high temperatures generated by friction with air particles.

The nose cone, having shielded a satellite as it travels through the atmosphere, may be separated from the satellite in outer space by an explosive cartridge In a missile, the warhead, together with auxiliary equipment, such as a fuzing system, is put into the nose cone

nutation, *n. Astronomy* A free but balancing motion of the earth's axis, in which its inclination to the plane of the ecliptic varies by a few seconds of arc, and the celestial poles describe wavy parallels about the poles of the ecliptic; any slight inequality in the motion of precession.

The constant of nutation for the earth is 9 21″ ***Lunar nutation*** is a perturbation due to action of the moon, ***solar nutation*** due to change in the sun's declination

O

orb, *n.* A spherical body, esp. a celestial sphere, as the moon, a planet, or a manmade satellite of that shape.

orbit, *n* The path described by a body in its revolution about another body, as by a planet about the sun or by a manmade satellite about the earth Sometimes used without an article, as in *to put in orbit, to be in orbit* (said of an earth satellite).

The orbit normally is an ellipse, thus, a line connecting the center of the orbiting body with the center of the primary body sweeps over equal acreas in equal times This means that the orbiting body moves fastest when nearest its primary body

orbit, *v intr.* Of a celestial body or manmade satellite: To revolve about another body.

orbital bomber. A projected bombing aircraft with the capability of near-orbiting or orbiting speeds to allow the craft to circle the earth once or more times at very high altitudes and then glide back to base.

Rocket propelled, an unmanned version could do reconnaissance, a manned version bombing

orbital glider. A vehicle that achieves sufficient velocity to attain an altitude so as to revolve

about the earth a desired number of times before falling (or gliding) back to earth.

orbital rocket. A rocket with sufficient range and speed to achieve an orbit about the earth.

orbital velocity. **1.** The average velocity at which an earth satellite or other orbiting body orbits. Cf. **separation velocity.** **2.** The velocity of such a body at any given interval in its orbit, as in 'its orbital velocity at the apogee is less than that of the perigee.'

When the orbital velocity is given at 17,000 mph. for example, this is considered to be in sense 1

ORDiR *(abbr).* 'Omnirange digital radar.'

outer space. **1.** In contexts of currently developing practical aero-space activities, the space above the earth's atmosphere, or above its effective atmosphere. **2.** Space beyond the limits of the solar system, as in 'an intruding meteor from outer space.'

In sense 1, the first sputnik is said to have orbited in outer space, but its orbit at 370 to 560 miles was well within the outer reaches of the earth's atmosphere It was reported as falling when its perigee declined and reached 120 to 130 miles

oxidizer, *n* A substance that combines with another to produce heat and, in the case of a rocket, a gas.

The oxidizer normally contains oxygen, or is itself oxygen, but it may be another substance, such as fluorine as used in an exotic fuel Chemically, an oxidizer increases the proportion of the electronegative part in a substance.

ozonosphere. A stratum in the upper stratosphere at an altitude of approximately 40 miles having a relatively high concentration of ozone and important for its absorption of ultraviolet radiation from the sun.

P – Q

pad, *n.* Short for 'launch pad.'

parallax, *n.* The apparent displacement of an object, or the apparent difference in its direction of motion, if viewed from two different points.

The parallax of the moon and sun may be observed in the difference between their angular altitudes above the bubble horizons and their angular altitudes above the celestial horizon.

parsec, *n.* A unit of measure for interstallar space equal to 3.26 light years.

The parsec has a heliocentric parallax of one second of arc

payload, *n. Specif.* In a rocket vehicle, that which is carried to obtain the results for which the vehicle is launched.

In a guided missile, the payload is the warhead intended to damage or influence the enemy, in a sounding rocket (which see) the payload comprises the instruments animal, or mechanisms sent aloft to obtain data; in a satellite rocket carrier, the payload is the satellite.

perigee, *n.* That point in an earth satellite's orbit at which it approaches nearest the earth. Cf. **apogee,** *n.,* sense 1.

perihelion, *n.* That point on a planet's or comet's orbit nearest the sun. Cf. **aphelion,** *n.*

The earth's perihelion is about 91,500,000 miles from the sun

period, *n.* The interval of time required for a periodic motion to complete a cycle.

perturbation, *n.* A disturbance in the regular motion of a celestial body, the result of a force additional to that which causes the regular motion.

For example, the center of mass of the solar system approximates the center of the sun, but it moves with regard to it in response to attractive forces of the planets This movement introduces perturbations.

Petrel, *n.* A Navy air-to-underwater turbojet missile developed by Fairchild.

The Petrel, by press reports, weighs 3,800 pounds, has a length of 24 feet, a span of 13 feet, a range of 50 miles, and homes by radar as an underwater torpedo

photon engine. A projected species of reaction engine in which thrust is to be obtained from a stream of light rays.

Although the thrust of this engine is considered to be minute, it can be indefinitely applied to build up speeds approaching the speed of light—186,000 mps.

photosynthesis, *n. Medicine.* A process found in green plants in which carbohydrates are formed under the influence of light with chlorophyl serving as a catalyst.

planetology, *n.* The study of planets and satellites, esp. in regard to the interpretation of their surface markings.

Polaris, *n.* A Navy solid-rocket IRBM designed to be launched from a surface ship or submarine, developed by Lockheed.

The Polaris may be launched subsurface.

postsputnik, *a.* Of or pertaining to time after the launching of the first manmade satellite, Sputnik I, 4 October 1957.

propellant, *n. Specif.* **1.** The mixture of fuel and oxidizer and sometimes an added chemical or chemicals, used in a rocket motor or rocket engine. **2.** Also applied singly to any one of the ingredients of a liquid propellant, i.e., to the fuel, the oxidizer, or to an additive. See **bipropellant,** *n.*, **liquid propellant, monopropellant,** *n.*, **solid propellant. 3.** Also applied to a fission reactor or fusion reactor.

Proxima Centauri. One of the two nearest known stars to the earth, about 4.3 light years distant.

The other nearest star, *Alpha Centauri*, is in the same constellation.

Quail, *n.* An AF air-to-surface cruise missile decoy undergoing development by McDonnell. Also called GAM-72.

R

radial velocity. The velocity of approach or recession between two bodies, esp. between an observer and a source of radiation, in a line connecting the two.

The magnitude and direction of radial velocity is determined by Doppler effect (which see).

radio command. A radio signal to which a guided missile, drone, or the like responds.

Ramo-Wooldridge Corporation. A private corpo-

ration, located in Inglewood, California, which carries out the overall systems engineering for the USAF in accordance with its responsibilities as technical advisor to the Air Force Ballistic Missile Division of Headquarters ARDC.

Systems engineering for the USAF is a function of the Space Technology Laboratories, The Ramo-Wooldridge Corporation

Rankine scale. [After W. J. M. *Rankine* (1820–1872), Scottish physicist.] (° R) A temperature scale that uses Fahrenheit degrees, but makes the zero degree signify absolute zero.

In the scale, water freezes at 491 69 degrees, and boils at 671 69 degrees Cf **Kelvin scale.**

Rascal, *n.* An AF guided aircraft missile (air-to-surface) developed by Bell esp for use by SAC aircraft. Also called GAM-63.

rato, *n.* ['Rocket assisted takeoff.'] **1.** A takeoff assist by a booster rocket unit normally using dry fuel. **2.** The power unit used in such a takeoff.

reaction engine. An engine or motor that derives thrust by expelling a stream of moving particles to the rear.

This engine works in accordance with the third law of motion, i e, every action produces an equal and opposite reaction. Jet engines, rocket engines, ion engines, photon engines are species of the reaction engine. Another reaction engine is reported in development—one that will utilize free radicals (which see) as fuel

reaction motor. A reaction engine, esp. one that is comparatively uncomplicated in design or operation.

reaction time. *Specif.* The interval of time between a command to launch and the actual launch.

Considered to be an attribute of a weapon or weapon system, as in 'the ballistic missile has a reaction time unmatched by a manned bomber.'

receptor, *n.* *Medicine.* A sensory nerve ending for perception of physical and chemical conditions of environmental agents and forces acting upon the body.

reconnaissance satellite. An earth satellite designed to obtain strategic information, as through photography, television, etc.

Redstone, *n.* An Army surface-to-surface liquid research rocket developed by Army Ballistic Missile Agency and produced by Chrysler.

The Redstone is reported to be 69 feet long, 6 feet in diameter, capable of mach speed, and with a range of 350 miles Its guidance is inertial. Its rocket motor is used on the Jupiter IRBM.

re-entry, *n.* The event occurring when a ballistic missile or other object comes back into the sensible atmosphere after being rocketed to altitudes above the sensible atmosphere; the action involved in this event. Attrib., as in *re-entry problem.*

re-entry trajectory. That part of a ballistic missile's trajectory that begins at re-entry and ends at target. See **free-flight trajectory.**

Regulus, *n.* Either of two Navy surface-to-surface turbojet winged missiles, developed by Chance Vought.

Regulus I is reported to be 33 feet long, 21 feet in span, 4½ feet in diameter, weighing 6 tons, with a speed of 738 mph and a range above 500 miles, guided by command radio or by homing *Regulus II* is 57 feet long, 20 feet in span, 7 feet in diameter, with mach 2 speed, and a range above 1,000 miles. Both need a booster rocket to get them airborne.

reliability research. The theoretical and applied research involved in developing test equipment to test test equipment, as in missile building.

remaining mass. The mass of that part of a rocket missile, rocket vehicle, or its payload that remains after the fuel or fuels have been exhausted, and after fall-away sections or parts have been cast off See **mass ratio.**

In the case of Jupiter-C and its satellite, the remaining mass was that of the last rocket stage, the steel shell within it, and the package of instruments within the shell

remote velocity. The velocity of an object taken as a whole relative to the surrounding fluid, as distinguished from the local velocity of any of its parts.

research rocket. A rocket vehicle used to determine the validity or reliability of data and equipment being developed.

right ascension. The arc of the celestial equator, or the angle at the celestial pole, measured eastward from the hour circle of the vernal equinox to the hour circle of a given celestial body, either through 24 hours or 360 degrees.

robo, *n.* A rocket orbital bomber. *Obs.*

robot bomb. An explosive-carrying winged missile or rocket, like the German V-1, normally launched from the surface and directed in powered flight towards its target by an automatic pilot and other automatic devices.

rocket, *n.* **1.** A rocket vehicle or a rocket missile. **2.** A rocket motor or a rocket engine, i.e., a motor or engine that moves itself forward by ejecting a stream of hot gases to the rear and is independent of the atmosphere for its operation.

The rocket (sense 2) is a species of reaction engine, but differs from a jet engine in that the latter is dependent for oxidation upon air taken in from the atmosphere whereas the rocket can operate in outer space, either by carrying its own oxidizer or by relying upon some other system to produce a jet stream, as with a nuclear reactor working upon a fluid

rocket, *v.* **1.** *tr.* To send an *object*, as an earth satellite or test sphere, into the sky by means of a carrier rocket. **2.** *intr.* Of a missile or vehicle: To move upward or forward in reaction to a rocket.

rocket engine. **1.** A rocket propulsive device that is relatively complicated in its workings, as distinguished from a rocket motor; hence, the liquid-fuel rocket device: See note and see **rocket,** *n.*, sense 2. **2.** In less exact usage, a rocket motor or, generically, any rocket propulsive device.

The liquid-fuel engine with its elaborate pumping equipment, pressure chambers, fuel lines, electrical connections, etc., is more appropriately called an engine, as in sense 1, than the solid-fuel motor. The term 'rocket motor'

is preferred over 'rocket-engine' as the generic term. See **rocket motor.**

rocket missile. A missile (which see) that uses rocket propulsion. See **rocket** *n.*, sense 2.

rocket motor. 1. In exact usage, a rocket propulsive device that burns a solid self-oxidizing fuel, as distinguished from a rocket engine. **2.** Generically, either the liquid-propellant rocket or solid-propellant rocket, or theoretically, the fission reaction or fusion reaction engine that emits a jet stream.

In sense 1. the device consists essentially of a combustion chamber that houses the grain plus a nozzle and igniter Cf **rocket engine.**

rocket propellant. A propellant used in a rocket.

rocket vehicle. A vehicle propelled by a rocket motor or rocket engine.

ruggedize, *v.* To make a *piece* of equipment rugged enough for practical use. *Popular.*

S

SAM *(abbr).* 'Surface-to-air missile.'

satellite, *n.* **1.** *Specif.* An attendant body that revolves about another body. See **center of mass. 2.** A manmade object designed, or expected, to be launched as a satellite. See **IGY satellite.**

scientist, *n.* A person learned in a science or sciences, accustomed and qualified to do theoretical and experimental research as he seeks out new principles or new knowledge. Cf. **engineer,** *n.*

second of arc. *Astronomy.* A measure of an angle, 1/60th of a minute.

selenocentric, *a.* Relating to the center of the moon; referring to the moon as a center.

sensible atmosphere. That part of the atmosphere that may be felt, i.e., that offers resistance. See **effective atmosphere.**

separation velocity. The velocity at which a space missile or space vehicle is moving when some part or section is separated from it; *specif.*, the velocity of an earth satellite at the time of separation from the carrier.

Sergeant, *n* An Army surface-to-surface solid rocket missile, developed by Sperry.

The Sergeant is reported to be 25 feet long, 3 feet in diameter, weighing 15 tons, with mach speed, and range of 75 miles Its guidance system is thought to be inertial

Shrike, *n.* A surface-to-air liquid-rocket guided missile being developed by Bell.

sidereal time. Time measured by reference to the apparent motion of the first point of Aries.

A sidereal day begins and ends when the first point of Aries is directly over the reference meridian Due to the motion of the earth around the sun, a sidereal day is almost 4 minutes shorter than the solar day

Sidewinder, *n.* A Navy air-to-air rocket missile developed for air defense by Philco and General Electric.

According to press reports, the Sidewinder is powered by a solid propellant, is 9 feet in length, weighs 155 pounds, and achieves a speed in excess of mach 2. It is guided by infrared

single-stage rocket. A rocket vehicle or missile provided with a single rocket propulsion system.

slenderness ratio. A configuration factor expressing the ratio of a rocket vehicle's length to its diameter.

sloshing, *n.* The back-and-forth splashing of a liquid fuel in its tank, creating problems of stability and control in the vehicle.

SM *(abbr).* 'Strategic missile.'

Snark, *n.* An AF surface-to-surface winged intercontinental air-breathing missile, developed by Northrop. Also called the SM-62.

The Snark, 69 feet long, 42 feet in span, 15 feet in diameter, weight 18 tons, has a speed somewhat less than mach 1 and a range of 5,000 miles It is powered by an axial-flow turbojet engine (the Pratt & Whitney J57), with rato

solid propellant. A rocket propellant consisting of of a single solid substance, usually a powder made into a grain of a particular size and shape. See **grain,** *n.* Cf. **specific impulse.**

A solid propellant consists of all the ingredients necessary for sustained chemical combustion It may be a heterogenous mixture of an oxilizing agent and a fuel, for example, crystals of perchlorate with asphalt, or it may be a chemical compound that provides its own oxidizer, as with nitrocellulose mixed with other chemicals to control rate and direction of burning

A solid propellant is also a monopropellant, but the latter term is seldom used to refer to it See **monopropellant,** *n*, note

solid rocket. 1. A rocket that uses a solid propellant. **2.** Short for 'solid rocket propellant.'

solid rocket fuel. A solid propellant.

sonic speed. The speed of an object at mach 1 relative to the surrounding fluid.

sophisticated, *a.* Of a weapon system: Complex and intricate; requiring special skills to operate. Accepted *slang.*

sounding rocket. A research rocket used to obtain data on the upper atmosphere.

The Wac Corporal and Aerobee were, or are, sounding rockets The Aerobee, exemplifying the equipment carried, has a radio antenna, telemetering equipment, telemetering channels, batteries, an animal container, a beacon, and a parachute This payload weighs 150 pounds. Recovered after flight, the sounding rocket gives up data additional to that obtained during flight.

space, *n.* **1.** That which extends in all directions, and has no outward bounds nor limits of divisibility, as in 'the sun and its planets move in space.' **2.** *Restrictive.* A part of this extension marked off or bounded in some way, as by the outer limits of the earth's atmosphere; *specif.,* the extent between the earth's atmosphere, or effective atmosphere, and an outer indefinite boundary, in which extent earth satellites may be put in orbit, ballistic missiles made to follow a plotted trajectory, or vehicles (manned or unmanned) moved about relative to spatial bodies.

In the specific sense of sense 2, this term is used as an attrib to designate various actions, things, or concepts associated with space as defined

Space is often conceived as void, but also as a receptacle in which matter is present in the form of meteors, meteoric dust, and radiation particles. Different extents of space have been usefully conceived as in the terms ***cislunar space, intergalactic space, interplanetary space, interstellar***

space, lunar space, and *terrestrial space*. See separate entries.

In sense 1, space, as conceived by non-Euclideans, is boundless but not infinite in extent; its conception is inseparable from the conception of time.

space biology. A branch of biology concerned with life as it may come to exist in space.

Space biology is a discipline used in the practice of space medicine.

space cabin. A pressurized and climatized cabin for use in space flight.

space laboratory. 1. A space vehicle carrying sensing and measuring instruments, recording equipment, radio-transmitting equipment, and other related instruments, used as a means of obtaining scientific data on conditions in the upper regions of the earth's atmosphere or in outer space. **2.** A vehicle that simulates the conditions of a space vehicle.

The space laboratory (sense 1) may be manned or unmanned

space law. A projected code of international law that would govern the use or control of space by different nations.

Andrew G. Haley and Theodor von Kármán have suggested that the line between the jurisdictions of air law and space law be drawn at the altitude where continuous flight by aircraft ceases to be possible, about 55 miles above the earth.

space medicine. An extension of aviation medicine concerned with the study, prevention, cure, or alleviation of illnesses or diseases expected to arise, or arising, from space flight.

space rocket. A rocket missile or rocket vehicle designed to reach the space above the earth's atmosphere, or, in some contexts, above the earth's effective atmosphere. See **atmosphere,** *n.*

space vehicle. A contrivance that carries something into or through space, either returning to the earth or not.

A space vehicle may be manned or unmanned, but is considered to be under man's control in at least a part of its flight The term is broad enough to include objects otherwise called guided or ballistic missiles if they are being considered as carriers of something through space

space warfare. Warfare conducted by use of weapons brought to bear upon earth targets from outer space, or brought to bear upon targets in outer space.

space weapon. A weapon that travels through space and is directed against an enemy target whether on the ground, in the air, or in space.

Sparrow, *n.* One or other of three Navy air-to-air rocket missiles: See note.

The *Sparrow I*, developed by Sperry, reportedly weighs 300 pounds, has a speed of 1,500 mph and a range of 8 miles, the *Sparrow II* is undergoing development by Douglas (December 1957), and the *Sparrow III*, developed by Raytheon, reportedly weighs 350 pounds, with a speed in excess of 1,500 mph

spatial body. Any body or aggregate of matter that exists in space and behaves in accordance with astronomic or astrophysical law.

This term includes the earth as well as celestial bodies. Cf. **celestial body.**

specific impulse. A performance parameter of a rocket propellant, equivalent to the effective

exhaust velocity divided by gravity, expressed in pounds per second. See **thrust,** *n.*

Some typical sea-level specific impulses for different propellants are listed not for absolute correctness, but as a comparative guide Liquid oxygen and ammonia, 255–265, liquid oxygen and ethyl alcohol, 243, liquid oxygen and gasoline, 242, liquid oxygen and hydrazine, 259, liquid oxygen and liquid hydrogen, 317–364, hydrogen peroxide and hydrazine, 252, nitromethane, 218; potasium perchlorate ($KClO_4$) and C_2H_4O, 165–210, potasium perchlorate and asphalt, 180–185, nitrocellulose, nitroglycerin, and additives, 205–230

specific thrust. Specific impulse.

speed of sound. The speed at which sound waves travel through a medium. See note and **mach,** *n.*

Sound travels at different speeds through different mediums, and at different speeds under different conditions of temperature, pressure, etc In air under standard sea-level conditions, sound travels at about 1,100 ft/sec or 750 mph.

sphere of gravitational influence. Gravisphere.

sputnik, *n.* Often *capitalized.* [Russian *s* 'with' *put* 'path' and *nik* 'agent,' i.e., 'that on a path with.] A satellite, esp. a manmade moon launched by the Russians, the first on 4 October 1957, the second on 3 November 1957. Cf. **Laika,** *n.*

The first sputnik, with a weight of 184 pounds, a diameter of 22 8 inches, and an orbital velocity of 18,000 mph, was put into an elliptical orbit ranging in height from 370 to 560 miles, and in a plane at 65° to that of the earth's equator The second sputnik, carrying a dog, was put into orbit at a maximum height above 900 miles, with an earth weight of 1,118 pounds, and a velocity of 26,250 fps or 17,897 mph. The estimated weight of the first rocket vehicle was 220,000 pounds, that of the second, 385,000 pounds

The full Russian designation is *Iskustvenyi Sputnik Zewli* 'artificial companion of the earth' The first satellite is often called 'Sputnik I,' the second 'Sputnik II.'

SSM *(abbr).* 'Surface-to-surface missile.'

stage, *n.* **1.** The interval of time in the flight of a rocket vehicle or rocket missile resulting primarily from the thrust of a single rocket motor, rocket motor cluster, or rocket engine. Used attrib. in combination, as in *three-stage rocket,* i.e., a rocket vehicle or missile designed to use three successive propulsive systems during powered flight. **2.** Also applied to any one of the rocket units that operate in such an arrangement, or to a section of the vehicle that contains such a unit, as in 'charges to break apart the three rocket stages.'

static firing. The firing of a rocket motor or rocket engine in a hold-down position to measure thrust and accomplish other tests.

static testing. The testing of a device in a stationary or held-down position as a means of testing and measuring its dynamic reactions. Said esp. of a rocket motor as a means of measuring thrust.

step rocket. A rocket with two or more stages.

strategic attack. *Specif.* An attack by means of long-range guided or ballistic missiles (together with long-range bombers or aircraft serving as launch platforms for air-to-surface missiles) directed at selected vital targets of an enemy nation so as to destroy his war-making capacity or his will to fight.

strategic missile. (SM) A guided or ballistic missile usually with a range in excess of 1,500 miles, designed for use in strategic attack (which see). The Atlas, Goose, Snark, Thor, and Titan are SM's. See separate entries.

stratosphere, *n.* **1.** A stratum of the atmosphere lying immediately above the troposphere and, as treated by some meterologists, immediately below the chemosphere. **2.** Also applied to a thicker stratum extending through the chemosphere.

As conceived in sense 1, the stratosphere, extending from above 7 miles to 19 miles, and characterized by horizontal and predominantly westerly air movements with a more or less constant temperature, is also called the isothermal region In sense 2, the stratosphere extends to about 50 miles.

subsatellite, *n.* An object designed to be carried into orbit inside an artificial earth satellite but later ejected to serve a particular purpose.

For example, an inflatable subsatellite has been designed to measure air density and satellite drag.

supersonic, *a.* Of or pertaining to the speed of an object moving at a speed greater than mach 1 relative to surrounding fluid. Cf. **hypersonic,** *a.*, **speed of sound.**

Technically, *supersonic* is generic and includes the concept of *hypersonic*, but some writers use it restrictively for relative speeds between mach 1 and mach 5 Use of *ultrasonic* as a synonym of *supersonic* is discouraged, it is a term of acoustics

systems engineering. *Specif.* The process of applying science and technology to the study and planning of an overall missile system, whereby the relationships of the various parts of the system and the utilization of various subsystems are fully planned and comprehended prior to the time that hardware designs are committed.

Use of the plural 'systems' refers to the many separate systems that must be combined in order to build an overall missile system. See **ballistic missile, note.**

T

takeoff weight. The weight of a rocket ready for takeoff.

This weight includes the weight of the vehicle, the fuel, and the payload.

Talos, *n.* A Navy ground-to-air missile developed by Bendix. Also called IM-70.

The Talos is 20 feet long, weighs 1½ tons, has a speed of mach 3 and a range of 25 miles Powered by a ramjet motor, it is guided by riding a radio beam.

tape recorder. An instrument that records on magnetic tape variations in electrical quantities such as current, potential, power, and frequency, the quantities then being subject to a playback with interpretations in sound, graphic display, or the like. Used in the telemetering equipment of man-made satellites or missiles, or in the recording of signals from a radio transmitter.

Tartar, *n.* A Navy ground-to-air rocket missile being developed by Convair.

telemeter, *n.* An electronic instrument that senses and measures a quantity, as that of speed, tem-

perature, pressure, or radiation, then transmits radio signals to a distant station, where, indicated or recorded, they are interpreted by code into the quantity provided for. Cf. **tape recorder.**

Telemeters are important instruments in earth satellites or test spheres, also in ballistic and guided missiles.

telemetry, *n.* The practical art of using telemeters. Attrib., as in *telemetry device.*

temperature, *n.* (temp) The relative hotness or coldness of a thing measured on a definite scale, esp. as a factor in employing space weapons or carrying out space operations, as in the re-entry problem of ballistic missiles.

The theoretical lower limit of temperature is absolute zero (approximately −273 16° C or −459 69° F), no upper limit is considered to exist See **Kelvin scale, Rankine scale.**

terrestrial space. Space comparatively near the earth in which the attraction of the earth is predominant.

Terrier, *n.* Either of two Navy ground-to-air missiles developed by Convair.

Terrier I, 15 feet in length, uses a solid rocket and attains a speed of mach 2 plus *Terrier II* is said to be guided by radar.

test equipment. Equipment used in testing the capabilities and characteristics of experimental operational equipment. See **reliability research.**

test failure. A failure to achieve a sought-after result by virtue of a miscalculation, inadequate equipment, or the like, during the research and development phase of a rocket missile or vehicle.

test sphere. *Specif.* A sphere designed to be rocket-carried to the expected orbital height of a satellite for purposes of testing equipment, esp. minitrack transmitters, prior to the launching of the satellite.

test vehicle. A vehicle, such as a rocket vehicle, used to test experimental equipment being developed for operational use.

thermosphere, *n.* The ionosphere considered as a region of temperature variation from −28° F to several thousand degrees.

Thor, *n.* An AF surface-to-surface liquid-rocket strategic missile, developed by Douglas. Also called the SM-75.

The Thor, in research and development, is an **IRBM.** Several test firings have been successful. It is considered an adequate vehicle for launching a satellite if adapted to the purpose

thrust, *n.* The force that drives a rocket missile or vehicle in a direction normally parallel to the longitudinal axis of the rocket, measured in terms of the fluid mass flow of its propellant in pounds per second multiplied by the effective exhaust velocity (relative to the airframe) in feet per second divided by gravity acceleration (at the equator 32.2 feet per second per second).

thrust cutoff. The stoppage of the reaction process in a rocket. Attrib., as in *thrust-cutoff point.*

Titan, *n.* An AF surface-to-surface strategic mis-

sile, developed by Martin. Also called SM-68.

The Titan, in research and development, is reported as having a range of 5,000 miles with an inertial and radar guidance system.

transistor, *n.* An electronic device that controls an electron current by the conducting properties of germanium or like material.

The transistor is similar to the vacuum tube in uses, but is itself a nonvacuum device.

translunar space. That part of space conceived as a spherical layer centered on the earth, with its lower limits at the distance of the orbit of the moon, but extending to several hundred thousands of miles beyond. Cf. **lunar space.**

This term is one of distance from the earth, not one of the moon's influence

Tritan, *n* A Navy surface-to-surface ramjet missile, developed by McDonnell.

The Tritan is 47 feet long, weighs 10 tons, develops mach 3 speed, and has a range of 1,500 miles It has inertial guidance and is submarine-launched

troposphere, *n.* The lower layer of the earth's atmosphere, extending to about 60,000 feet at the equator and 30,000 feet at the poles.

The thickness varies with the seasons and with different meteorological conditions

Tsiolkovsky, K.E. A Russian engineer and scientist (5 Sep 1857–1935) whose paper "Rockets into Cosmic Space" (1903) was one of the pioneer works in the achievement of rocket flight.

tumble, *v. intr.* Of an oblong earth satellite: To rotate about its horizontal axis, end-over-end. Said of Sputnik II.

U – V

umbilical cord. Any one of the servicing electrical or fluid lines between the ground and an uprighted rocket missile or vehicle before the launch. *Figurative.*

universe, *n.* The entire spatial cosmos.

unobtainium, *n.* A substance having the exact high test properties required for a piece of hardware or other item of use, but not obtainable either because it theoretically cannot exist or because technology is insufficiently advanced to produce it. *Humorous* or *ironical.*

upper air. *Geophysics.* That part of the atmosphere that embraces the ionosphere and the exosphere.

V-1. [Abbr. of German *Vergeltungswaffe eins* Revenge Weapon One.] A German robot bomb (which see) used in WW II. Also called the FZG-76 by the Germans, and the buzz bomb by the British.

The V-1, first launched across the English Channel on 13 June 1944, was powered by a pulsejet engine mounted on its back It had a speed of about 360 mph, a range of 150 miles, and flew at 2,000 to 3,000 feet altitude Some 2,000 of these weapons were directed against England in WW II

V-2. [Abbr of German *Vergeltungswaffe zwei.*]

A German liquid rocket, developed as a ballistic missile in WW II.

The V-2, first launched against England on 8 Sep 1944, developed 60,000 pounds of thrust. Without wings, it was subject to some guidance through movable panels built into the four tail fins and through graphite vanes extending into the exhaust stream Launched vertically, it reached a speed of 3,600 mph, then tilted in the direction of its target, reaching an altitude of about 60 miles with a range of 200 miles, and then plunging earthward without power at about 1,500 mph Some 1,115 V-2's were sent across the channel in the last six months of WW II After the war, the V-2 became a research rocket in both the US and Soviet Russia One of its test flights in the US is said to have reached a height of 120 miles.

Vanguard, *n.* **1.** A project of the US Naval Research Laboratory concerned with developing a carrier rocket and satellites, the latter to be placed in orbit during the International Geophysical Year. Officially called 'Project Vanguard.' **2.** Short for 'Vanguard carrier rocket' or 'Vanguard satellite.'

Vanguard carrier rocket. A three-stage carrier rocket developed under Project Vanguard for placing a satellite in orbit.

This carrier rocket, 72 feet in length and 22,600 pounds in weight, is a modification of the Viking with a slenderness ratio of about 19 to 1 Its first two stages use liquid propellants, its third a solid propellant Its horizontal velocity increment totals 25,817 ft/sec or 17,603 mph

Vanguard satellite. A satellite designed for, or adapted to, the Vanguard carrier rocket for launching. See **IGY satellite.**

vanishing-man concept. A concept of warfare that visualizes more and more use of robots, machines, and automation with a corresponding use of fewer and fewer men.

This concept is not to be considered necessarily valid.

velocity, *n.* **1.** A vector quantity that includes both magnitude (speed) and direction relative to a given frame of reference. **2.** Commonly used as a synonym of speed.

vernal equinox. The point where the sun appears to cross the celestial equator from south to north. Also called 'the first point of Aries.'

vernier engine. [Named after Pierre *Vernier* (1580–1637), French mathematician.] A rocket engine of small thrust used to obtain a fine adjustment in the velocity and trajectory of a ballistic missile just after the thrust of the final stage main engines has been cut off.

vertical launch. A launch in which the missile or vehicle starts from a vertical position.

Viking, *n.* A liquid research rocket built by Martin and Reaction Motors for the Navy, first launched 3 May 1949.

The Viking, a single-stage liquid rocket, in length from 42 to 48 feet, in diameter 32 inches, weight between 9,650 and 15,000 pounds, developed a thrust of 20,000 pounds for 75 seconds Modified, the Viking is the first stage of the Vanguard carrier rocket.

This rocket was called 'Neptune' in its early development It was also nicknamed 'Marco Polo' by persons who worked on its manufacture.

W – X – Y – Z

Wac Corporal. A sounding rocket for very high

altitudes, developed by the Jet Propulsion Laboratory during the late 1930's and 1940's.

The Wac Corporal was 16 feet long, 1 foot in diameter, weighed 665 pounds with fuel (280 pounds dry weight) and payload, and was propelled by liquid fuel. Adapted for use as a second stage of the V-2, it reached an altitude of 250 miles on 25 Feb 1949 at White Sands Proving Ground, New Mexico.

warhead, *n.* That part of a missile that constitutes the explosive, chemical, or other charge intended to damage the enemy.

weapon system. (WS) A total complex (embracing design concepts, production, hardware, logistical support, training measures, maintenance and operating manpower) that goes into the development, production, and employment of a weapon.

A given ballistic missile, for example, is more than a missile At first, it is considered the best possible design for its purpose—in terms of the length of time for its development and production, the number of men to handle it, the amount of training in specific AF specialties, its workability under combat conditions Then settled upon as a practicable design, each of its subsystems (guidance, propulsion, etc) must be developed under coordinated control called 'systems engineering.' Created as a piece of hardware, it must be tested, maintained, and supported As it reaches production, ground crews must be brought to a peak of training to handle it Thus conceived, the ballistic missile is a weapon system; it contributes to doctrine and sets war plans

weightlessness, *n.* A property or attribute of being without weight.

If a body has overcome the gravitational attraction of the earth (or other spatial body), as by velocity, it is without weight, since weight is defined as the product of the body's mass times the acceleration of the body due to gravity.

Wizard, *n.* An AF ground-to-air missile system in research and development by Convair and RCA.

WS *(abbr).* 'Weapon system.'

WS-110. A projected manned bomber expected to develop speeds of mach 3 and the capability of staying aloft for several days flying at above 75,000 feet.

WS-117L. A reconnaissance satellite being developed by Lockheed.

WS-131B. An AF air-to-surface missile undergoing development by North American.

WS-132. An AF air-to-ground missile undergoing development by North American for launch from a B-52.

X-15. A rocket research aircraft in research and development, with the National Advisory Committee for Aeronautics (NACA) the technical director acting for the USAF and the Navy.

Begun in December 1954, the X-15 is scheduled to fly in 1959 North American Aviation and Reaction Motors are the contractors With a length of 50 feet, a diameter at the tail of 4 feet, short blunt wings of 22 feet span, a gross weight of 16 to 16½ tons, an inertial guidance system, the X-15 is expected to range as high as 300 miles at speeds of mach 5 to mach 7 in terms of lower atmospheric flight. The X-15 is to be manned.

X-17. A rocket test vehicle being developed by Lockheed.

zerogravity, *n.* A condition existent when the centripetal gravitational attraction of the earth or other spatial body is nullified by inertial (centrifugal) forces.

Ziolkowski. Variant of TSIOLKOVSKY.

Mr. FELDMAN. Are there techniques for penetrating cloud cover from a reconnaissance satellite?

General BOUSHEY. Yes, sir; I believe there are. I am sure you are acquainted with radar which works through cloud cover, and infrared will work as long as the cloud cover is not too deep.

In other words, infrared detection is possible through a certain measure of water vapor. Water vapor seems to attenuate it more than other gases.

Mr. FELDMAN. Were you not for a brief time a director of astronautics in the Air Force?

General BOUSHEY. I think it was a day and a half, sir.

Mr. FELDMAN. What happened to your projected office?

General BOUSHEY. It was disestablished, sir.

Mr. FELDMAN. Has ARPA taken over all the functions you would have had?

General BOUSHEY. No, sir. We still do them.

Would you like me to explain that, sir?

Mr. FELDMAN. Yes.

General BOUSHEY. I was the Deputy Director of Research and Development. The Air Force felt after the Sputniks I and II were launched, that it would be worthwhile to have a small office in the air staff to give full time and attention to space matters. I was selected. It was to be a very small office not to exceed 10 people, about 5 military and 5 civilian, and this would help Secretary Douglas, General White, and others on the staff, on space matters.

This office was disestablished because I understood ARPA was then in the process of formation and they wanted to find out how ARPA would work with the services before a service established any particular staff office of its own labeled "Astronautics."

Colonel Dillon and I have been the only two working on this for months, on the same job under a different name.

Mr. FELDMAN. One last question. We have heard a lot about the cost of these various ventures and explorations. What about the payoff in terms of weather control and communications, and so on?

General BOUSHEY. Sir, I agree that the payoff would be probably so valuable that we cannot even appreciate it at this time.

Again I hate to refer to this TV movie of the Russian film, but they even pointed out the possibility of very valuable minerals on the moon. This might catch the imagination, but I think there will be other things that are more valuable than minerals. It might be new knowledge and new things that we discover.

Mr. FELDMAN. In the form of weather control or weather prediction itself, you might be able to control floods and things of that sort. Is that not so?

General BOUSHEY. If you could not control them, we could at least give warning, sir.

Mr. McDONOUGH. Yesterday we had a witness, Dr. Simon Ramo, and he said that the benefit from weather predictions by satellites in orbit for that purpose alone would be more valuable to the military than it would be to civilian uses. If we knew, in launching or shooting an ICBM, what the weather conditions were at the point of target more accurately than we do now, then we would be more accurate in our firing.

Now, you are a military man. What do you think of that?

General BOUSHEY. I think he is probably correct, sir.

Mr. McDONOUGH. What do you think of the possibility of transportation, worldwide transportation, by a satellite in orbit?

General BOUSHEY. I do not think that is an efficient use of a satellite.

Mr. McDONOUGH. I say a satellite—a controlled satellite, a controlled space vehicle.

General BOUSHEY. You are referring to something like ICBM for transporting supplies or humans?

Mr. McDONOUGH. Yes.

General BOUSHEY. I think it would be a very expensive way to do it. While I won't discount there might be a need, I don't see it.

Mr. McDONOUGH. In communications, for instance, would that be a great benefit to the military at the present time?

General BOUSHEY. And civilians as well, sir; very great.

Mr. McDONOUGH. So that the major things that we might obtain as a byproduct for civil uses from the experiments on the military side are weather prediction, communications, and transportation, for whatever it may be worth?

We could at least find out whether it was profitable. Are there any other things in satellite return that we might anticipate?

General BOUSHEY. Yes, sir, I believe the Navy has proposed that they could put a satellite in orbit and use it as a most useful means of navigation; that is, navigation at sea.

They could detect this satellite by both radar and optically, perhaps at midday. I would be what they call a stationary object and stay at one place over the equator and rotate at the same angular rotation that the earth does.

It would then be just a matter of measuring the angle to know where you were as regards latitude and longitude.

Mr. McDONOUGH. It would be like the stars?

General BOUSHEY. Better than that. It could be quite accurate, I have been told.

The CHAIRMAN. Gentlemen, you will have an opportunity to edit your testimony.

We hope you will enlarge where you think it will be helpful and clarify your remarks.

In other words, you can add new thoughts in the editing of your testimony.

For myself and members of the committee, I express our appreciation to you for your appearance and for your testimony.

General BOUSHEY. Thank you, sir. I consider it a privilege to be here.

The CHAIRMAN. The Chair understands outside the committee room are 50 Girl Scouts from Mrs. Rogers' district. This is a good time to suspend for the moment.

(A short recess was taken.)

The CHAIRMAN. The committee is very glad to have you young ladies here. You see a committee in operation. This is the hearing room of the committee which your distinguished Representative, Mrs. Rogers, is a very prominent member of, and was chairman of when the Republicans were in control. I might say she is one of the ablest Representatives we have in Congress. I have a very high regard for

25973 O—58——38

Mrs. Rogers as a legislator and as a great American. We are glad to welcome you here.

Now, the next witness will be Dr. Raemer Schreiber, leader of N Division, Los Alamos Scientific Laboratory, of the Atomic Energy Commission.

Doctor, we will be very glad to hear from you.

STATEMENT OF DR. RAEMER SCHREIBER,[16] LEADER OF N DIVISION, LOS ALAMOS SCIENTIFIC LABORATORY, ATOMIC ENERGY COMMISSION

Dr. SCHREIBER Mr. Chairman, I have assumed that what you would like to hear is a story of the nuclear rocket propulsion program or the Rover program. While I do not have a completely written out statement, I have a prepared statement which I can present and then be available for questions after that, if it is agreeable with you.

The CHAIRMAN. You may proceed any way you wish, Doctor.

Mr. SCHREIBER. Thank you.

The Rover program, which is the nickname for the nuclear rocket propulsion development, is being supported by the Atomic Energy Commission and by the Air Force. It is administered by Maj. Gen. Donald J. Keirn, who wears two hats essentially. He is the head of the Aircraft Reactors Branch of the Division of Reactor Development for the Atomic Energy Commission, and he is also a Deputy Assistant Chief of Staff for Development in the Air Force headquarters. His deputy is Col. J. L. Armstrong.

This work under the AEC which I am directly concerned with is assigned to the Los Alamos Scientific Laboratory and I am head of the division which has been given the major responsibility for this program.

I would like to say that I am not directly cognizant of the Air Force support of this work, although I naturally keep up to date on it reasonably well. This is handled primarily by contract from the Wright Air Development Center to the Rocketdyne division of North American Aviation and the Aerojet General Corp.

What I would like to do, since you have had many expert witnesses talking about the missions which might be accomplished, is to concentrate on the technical program and tell you something of the reasons why we are interested in this, why we think the Nation is interested, and something of the way we are going about it. In order to do that, I will have to remind you again of some rocket fundamentals and I will try not to be too painful about this, but I do have a point I would like to make.

If you are dealing with long-range rockets, you are dealing with very enormous amounts of energy. You must have this source of energy, you must be able to expend it usefully in a very short period of time, and you must do it in a fashion which gives you the maximum thrust to your rocket for the amount of material which is carried simply because a rocket, when it starts its operation, must carry

---

everything with it which it uses. The amount of energy involved is really quite large.

A large missile, for example, requires for a short period of time something like 3 million kilowatts of power. This is like taking the entire amount of electricity needed for a city the size of Chicago, and putting it through an engine about the size of an office desk. You don't do it for long, but you must do it over a period which is, maybe, a few minutes.

Now, in chemical systems, the source of energy, of course, is the propellant, which is an oxidizer and a fuel which is either mixed in the chamber in the case of the liquid system or is in some safe chemical combination in the solid propellant system and, upon being heated ignites and burns and you get the thrust by ejecting the exhaust gases, the combustion products, at high velocity through a nozzle.

In order to get a measure of the effectiveness of this thrust, there are some terms which undoubtedly are in these glossaries which one must define. But, basically, the measure of the effectiveness of this thrust is what is known as specific impulse, which is the pounds thrust per pounds per second of the propellant which is ejected. This also is proportional directly to the exhaust velocity. The higher the exhaust velocity, the more thrust one gets per pound of propellant which is ejected.

Now, this enters into the calculation of the size, the weight of a rocket, in a fashion which I will not go into, but it is relatively simple. It results in what is known as the vehicle mass ratio, which is the ratio that the vehicle has to start with divided by the mass which it has when it has exhausted its fuel. This, then, is determined by a very powerful function involving the ratio between the velocity you achieve and the velocity of exhaust of the propellant.

Rather than to try to give a lot of illustrations of this, let me take a specific example.

Suppose that you ask for a velocity of 16,000 feet per second. This is about what is needed for a 1,500-mile terrestrial mission, ground to ground. Suppose also you have a chemical system which has an exhaust velocity of 8,000 feet per second, or specific impulse of 250. This is common to existing chemical motors. Then you do the calculations and find that you must have 7 pounds propellant burned for every pound you put into this velocity of 16,000 feet per second. This is not too bad. This means that you have 15 percent of your gross takeoff weight left for the engine, controls, structure, the tankage, and the payload.

Suppose they ask that you go up to about 30,000 feet per second, which is about what is required for a low-level satellite if you make some allowance for atmospheric drag and work done in working against gravity getting to altitude. Then this number of 7 pounds goes up to 40 pounds. So now you have left only 2½ percent of your gross takeoff weight for the structure, the engine, et cetera, and the payload. This turns out to mean that you don't get to the payload because you don't have enough weight allowance. Obviously what you do in this case then is to stage. You ask that, say, it all go up to only half of the final velocity and then you put on as part of the payload of the first stage the second stage, which does not weigh as much, and this is the course which is actually followed.

In principle, one can get some fraction of this takeoff weight into an orbit. It is probably unfair to regard Explorer and Vanguard as representative of the best chemical missiles because they have been done on a short time scale and with available equipment, but it is interesting to note that they only get 1 pound of useful payload out of between 1,000 and 2,000 pounds of takeoff weight in these particular cases.

You can go on up in performance demands, and suppose you want to do a soft landing on the moon or a one-way mission to Mars (and I could get into an argument with the other people on what it really requires), but let us assume it requires 60,000 feet per second. Then it calls for 1,800 pounds of propellant burned for each pound you get there, and this is the theoretical upper limit. You can't beat this. The laws of physics tell you you cannot do better than this. But something less than this probably can be done by making many stages.

However, you have again a question of reliability. If you have many stages, all of which must work, for example, if you have four stages and they are each 90 percent reliable, then the probability of actually completing the mission is only 66 percent. So the use of many stages has certain drawbacks quite aside from the fact that it is quite difficult to get a large amount of weight delivered.

If I wanted to really push this to the extreme and talked about 75,000 feet per second, which maybe gets you back from Mars or something of this sort, now you are at a limit of 11,000 pounds of propellant for each pound that you deliver, and you cannot beat that with a specific impulse of 250.

Now, all I am trying to do here is to say that if you are really interested in these ambitious missions, you really want a higher specific impulse. Then you ask, How is the best way of going about this?

With chemical systems, it is possible in principle to go up to something like 400 pounds thrust per pound per second or, to use the abbreviated form, 400 seconds. This is an increase of from 250 to 400, and this pays off very considerably. This permits one, for example, to get about 1 percent, theoretically, of your takeoff mass up to 60,000 feet per second. So you can talk then about 1 percent split up into many stages, and this again you cannot beat by any scheme.

On the other hand, if you can increase this specific impulse by rather a substantial amount, and I am taking a factor of 3 over the original example, say 750 seconds, then it is just as easy to do a 60,000-foot-per-second mission as it is to do a 20,000-foot-per-second mission, with 250 seconds, and you come back to 3 or 4 pounds as the required propellant weight. Clearly, if this could be done very cheaply and quickly, we would do it at once. It is not so quick and cheap, but we feel that the method of nuclear propulsion offers a very good probability of accomplishing this.

So the question is then, What can nuclear propulsion do which chemical systems cannot? You can go back then and you say, in the first place, you must have a source of energy and this is clearly no problem, because the amount of energy stored in nuclear form is about 10 million times that of chemical.

Then you ask, How can I convert this into a useful form?

Mr. McDonough. Is that an arbitrary figure you are speaking about when you speak of 10 million times?

Mr. Schreiber. You take the energy in a pound of uranium 235 and compare it with an average sort of energy in a chemical explosive or chemical propellant and it comes out in this order of magnitude. I

will not guarantee whether this is 1 or 6 times that, but it is so large that actually there is no problem at all in having this energy available in a very compact and lightweight form.

Then you ask, How can one really make use of this?

The obvious solution, the classical illustration which you probably have had presented here already, is to essentially combine the features of chemical rockets and of nuclear reactors. And instead of burning the propellant to get the energy, you heat it up by passing it past a solid fuel reactor. This is the "Old Pokey" concept which I think Dr. Merkle talked about a week or so ago.

Then you ask, well, this is fine, but what have you accomplished, because you have obviously substituted a new system here, you have introduced possibly some new problems, and can it really accomplish very much?

Here again I must go back to the basic ideas of how the specific impulse depends upon the characteristics of the propellant, and basically, the two factors are the temperature of the propellant and its average molecular weight.

We are now going to talk about this wedding of the reactor and rocket engine. In chemical systems, you are already pushing the limits of material melting point so we cannot do much with the temperature. However, you can do something about molecular weight.

In the chemical system, the molecular weight is determined by the fact that you have combustion products, such as water vapor and carbon dioxide, and these have molecular weights of 18 or higher.

In nuclear systems you have a single propellant which you can adjust, and obviously the lowest molecular weight is hydrogen with a molecular weight of two. Since the dependence is the square root of this ratio, you come up with a factor of three in specific impulse in operating a nuclear hydrogen system at the same temperature as the chemical system.

So this in principle, you see, gives us a factor of 3, which I talked about in saying you can do a 60,000-foot mission with the same difficulty as you can a 20,000-foot mission in terms of this particular parameter.

Now it is quite a long story as to whether you can do this, what weight of system you need, what the complications are, but here at least is a first approach which could be looked at and, let us say, does not depend too much on imagination. It is somewhat within the state of the art and is specifically, I think, an engineering development.

Now, if you say this is still not good enough, you want to do better, there are of course ideas all over the country, there are ideas on going not to solid fuel as such but fluid fuel. You deal with a liquid uranium compound or a gaseous compound, and then are not restricted in temperature.

Furthermore, if you go up into the very high temperatures, one starts getting into the disassociation and ionization phenomena which constitute new ways of taking the heat out of the fission process and putting them into the propellant.

Now, I present this as a rather lengthy introduction in order to say two things: that a higher specific impulse, a higher level of performance, is certainly of interest if we are talking of space exploration, and, second, that there are ways of using nuclear energy in which this can be done.

That is essentially the basis on which the Rover program has been started. It has been going for 3 years. Rather, I should say it started 3 years ago and it took quite a bit of time to get up momentum.

Our guidance from the AEC was an instruction to explore the feasibility of the nuclear rocket systems, and it was left to the laboratory to determine the best way of doing this. In view of the fact that this was an early exploratory effort, it was very desirable to have this freedom, but we did have to make up our mind which way we were going to approach the problem.

There are obviously two extremes. One is that you can grab on the thing which seems to be most available, concentrate all effort on this, and press for a quick result. This is rather risky. If you fail, you have failed in a fashion which will make it difficult to pick up the pieces and go on. The results probably would not be as good as though one had settled down to the other extreme, which would be to start basic research in materials, radiation effects, reactor operations, and so on and on, but this could go on also, however, for a good many years and might not give you a practical result.

The guidance that we had and the things that we listened to were fairly conflicting. There were some people who would say we must have this done in a hurry, so that if there is a serious defect in the chemical propulsion system, we need nuclear propulsion for defense purposes, we must have something ready to go.

There were other people who felt this could be a program which could be pursued in a fairly leisurely fashion. It was an interesting byproduct of the missile and atomic age, and sometime in the near future we might be interested in using this. Since we could not get any coherent opinion, we had to make up our own minds and undertook a combination of some specific design work and some basic research work. The specific design work which was undertaken is resulting now in the test reactor which I think has already been announced will be put in the test stand at Nevada near the end of this year. We are still continuing this dual approach, and we think that it has a considerable merit. By having specific problems to point to, the basic supporting work is given some direction and it does not wander around over a wide field without discriminating between the trivial and the important problems.

On the other hand, having supporting research which is not rigorously tied to the specific development problem, we occasionally have the happy surprise of having a solution readymade when we run into the practical problem or of having a suggestion of a way of avoiding the problem altogether.

Now, the talents which are required for this sort of work cover a fair variety of fields. It is clear that, no matter what specific system is used, one is always interested in pushing to the maximum temperatures possible. This means that work must be done on the study of the properties of high-melting-point materials, and these are obvious to anyone who goes through a handbook. There are things like graphite or carbon, tungsten, molybdenum, tantalum, the carbides of these metals, and others, oxides and so on.

Very little work has been done in the extreme high-temperature field. It has been discouraging to find that when we got a lead on somebody that had been doing high-temperature research that he thought that 1,500° F. was real hot. This means that there is a lot of basic work that must go on.

Clearly, a reactor is not going to operate unless there is some fissionable fuel in it, so one must study the behavior of uranium and plutonium compounds to see how they stand up under various conditions. So there is a great deal of basic-materials work required. Then, if you are going to get serious about a specific design, you have to ask what are the properties of these real materials, how do they behave under thermal stresses, under mechanical loads?

And then finally, since your reactor is not going to just sit there and glow quietly, but must be exchanging heat to some propellant which is roaring through it at a great rate, there must be studies of the interactions between the proposed propellants and the fuel materials.

We have, for example, at Los Alamos, a bank of four submarines' worth of storage batteries. These are all hooked up with massive bus bars and switches so that we can short-circuit the output of this through a test specimen in order to give some simulation of the power densities which are required in these rather high-power-density reactors.

In terms of the reactor studies themselves, the problem is not too different from the development of a power reactor, although the requirements are here more stringent in some ways.

One thing in our favor is that we are not expecting these to run for years, but only for minutes. Therefore, tests can be conducted relatively quickly.

On the other hand, these reactors must be brought up to power in periods measured in seconds rather than in hours or days, as in the case of power reactors, and they must respond to command signals within fractions of a second if they are to operate successfully. So this calls for a combination of rather extensive calculation and experiments to see how reasonably good mockups of these reactors will work. In fact, at Los Alamos we have a rather extensive remote facility for making these assemblies and actually operating these reactors at low power. This is, of course, due to the bomb physics work which has been going on there. This permits us to go through, in a reasonably short period of time, either an exploration of a new concept or the much more detailed study of a more specific mockup. We actually will check out the real reactors there again at extremely low power before they are put on the test stand. The control of such a reactor must operate in a very short period of time. There is not a time for an operator to sit there and read meters and scratch his head and decide what to do next. The command signals must be given in a short period of time. So there must be an elaborate combination of high-speed digital computer and real time and analog computer work in studying the dynamics of the system. Actually, the control system for the operating reactor has to have in it several digital computers which take the power, the flow level, similar signals, compare those with the desired conditions, and then transmit correction commands to the reactor; and all this must be done in fractions of a second.

I have mentioned the rather elaborate calculations that are required. This obviously calls for machines and technicians, but it clearly takes much more than this. Machines give you back nonsense if you put nonsense into them. So this program calls for a rather strong theoretical support where the problems can be analyzed in

terms of the physical laws and then reduced into terms which can be solved either by hand or by means of a machine.

There is, finally, the problem of integral testing. You first must design and build the test device out of real materials, not hypothetical materials that someone has used on a conceptual study; and then you must decide on the information which is to be obtained and instrument this is an appropriate fashion; and then finally this has to be actually put through an operation.

As you know, there has been an area at the AEC Nevada test site developed for the Rover work. For those of you who are familiar with the area, it is about 12 miles almost due west of the base camp at Mercury. It is in a region known as Jackass Flats. We hope this does not have any adverse connotation. Anyway, we have in almost the final stages of construction a test area there which has three major installations located approximately on an equilateral triangle, on the points of such a triangle.

There is first the control building, from which the reactor's test devices are operated and which have all of the data-recording equipment and a small administrative area associated with this.

On another point of the triangle is a maintenance assembly and disassembly building, which of course became abbreviated to the MAD building and in this the reactor is assembled in an ordinary, fairly large room with a crane, and it is disassembled after its operation in a large shielded hot cell, which is somewhat similar to the installations at ARCO, the reactor testing ground up there. The reactor is assembled, I should say, on a test car which runs on a standard railroad track and is then hauled out to the third installation, which is the test cell area proper, where it is plugged into the test cell and finally connections are made and the system is checked out. Then this area is cleared and the operations conducted from the control room. After the test is over, the reactor on its test car then is brought in by a remotely operated locomotive which brings it in and shoves it into the hot cell of the MAD building where it is then disassembled for final inspection and post mortem.

The samples which are of particular interest are placed in shielded containers and returned to Los Alamos for further inspection.

I should say a few words about radiation and fallout since this is a very sensitive subject these days. The direct radiation from the reactor in the immediate vicinity will be very intense. We are operating these test devices unshielded and there will be problems of radiation heating and damage very close to the reactor. This is part of our study, to see what these are.

This radiation falls off very rapidly and at a distance of a few hundred feet there is no problem as far as material is concerned, and our control building is at a distance of about 2 miles—one can stand outside there and watch the test.

Now, contamination—and by contamination I mean the ejection of fission fragments with the coolant or propellent from such a test device—there is expected to be some. If one takes the most pessimistic case which naturally we hope will not happen, that is, you go through your complete run and the last second the whole reactor blows up and sprays all of the fissionable products into the atmosphere, in that case one is only talking about an energy release which is a fraction of a kiloton.

So we cannot believe that anything more than quite local contamination would result from this. A contribution to a large area or world fallout simply cannot be a large problem here.

I have stated in a general way how we are going about this. I suppose you would like me to come to the point and say what can be done here. Actually, I think I would be misleading you if I pretended to lay out a blueprint for a series of space missiles using nuclear power, because this is exactly what our present program is trying to determine. But I think we can say that we have no desire to re-do what chemical systems have already done, that we have some feelings which I think are quite firmly founded as to what sort of missions make sense. We are talking about payloads, I think, which are not less than 10 tons. We are talking about performance which is not less than a very long-range ICBM.

This is a point at which the best chemical systems and the nuclear systems, let us say, are competing. Beyond that, we feel that nuclear systems have a very considerable advantage.

Now, as to the upper limit, it is almost impossible to say. Certainly, as far as the reservoir of energy in nuclear power is concerned, there is no practical limit. The limitation is in how you apply this, how do you get the work out usefully. There you say, we cannot any more deal with solid materials. Then someone will propose a liquid or gaseous system and you cannot prove it will not work without doing some analysis. And perhaps you find that it indeed will work.

If this is not good enough, then one talks about the transition over into the ejection of very high velocity particles. You get very close to the ionic propulsion. In other words, we feel there is not any sharp boundary between these two areas.

This sort of atmosphere in which one tries these very advanced ideas is one of the things which makes us rather excited about this program. However, a lot of them will not work. We will not know whether they will work or not until we actually make some studies.

It is possible with a relatively inexpensive program to do quite a bit of evaluation of this sort. Now, as to whether this will all work, I would just like to make the statement that I do not believe that the senior people, at any rate, who have been spending their efforts in nuclear rocket propulsion would be doing this if they do not believe that there is a potential here for a performance which is far beyond the best chemical systems and, also, if they did not believe that the Nation would some day want to have this potential. So people are working in this. It is probably too early to make very concrete statements about what the ultimate result of this is.

I think that ends my prepared statement.

Mr. NATCHER (presiding). Doctor, you have made a fine statement to the committee and we certainly appreciate it. There are a number of questions that the members of the committee and our director would like to ask, Doctor. If it meets with your approval, we still stand in recess until 2:30, at which time we will then direct our questions to you concerning your statement.

Dr. SCHREIBER. Fine, thank you.

(Thereupon, at 12:10 p. m., the hearing was recessed, to reconvene at 2:30 p. m., same day.)

AFTERNOON SESSION

Mr. NATCHER. Dr. Schreiber, will you come around, please?

STATEMENT OF DR. RAEMER SCHREIBER, LEADER OF N DIVISION, LOS ALAMOS SCIENTIFIC LABORATORY, ATOMIC ENERGY COMMISSION—Resumed

Mr. NATCHER. Doctor, one of the main duties to be performed by this committee is to make the necessary recommendations concerning legislation pertaining to research and the problems of flight within and outside the earth's atmosphere. Have you had a chance to examine the bill which is before the committee at this time?

Dr. SCHREIBER. I have seen the bill. I have not studied it, but I have seen the main provisions.

Mr. NATCHER. Under the terms of this bill, a director is to be named by the President, to be confirmed by the Senate. What type of qualifications do you feel that the director of this new agency should have, Doctor?

Dr. SCHREIBER. He has to be somewhat of a superman, but I guess that is not a very helpful statement.

Mr. NATCHER. First, let me ask you this: Are you in favor of this agency being controlled by a civilian group, that is, having civilian control?

Do you favor that procedure, Doctor?

Dr. SCHREIBER. Anything I say in this regard, I suppose, is mostly a personal reaction. I definitely would be in favor of civilian control. My experience has been with this sort of control and I feel that you have a better continuity, a longer range point of view, than with a direct military responsibility in which the immediate problems also must be solved.

I do not know that one can make any generalities. It depends so very much on the framework in which this is set up and philosophy under which it is operated, but I would say that a civilian agency is definitely to be preferred.

Mr. NATCHER. The bill before us also provides for a board of not to exceed 17 members.

Now, basing your answer upon your connection with the Atomic Energy Commission, and knowing how that organization functions, do you believe that the board should have as many as 17 members or should it be a board of less than that number?

How do you feel about the number of members on the board?

Dr. SCHREIBER. As an advisory board, I suppose it does not matter too much except that as many as 17 members somehow seems to be an awful lot.

Mr. NATCHER. Under the bill, it provides that eight members shall come from Government agencies, with the Department of Defense to have one member, and the balance to be composed of other members to be designated.

I am inclined to agree with you as to the number. I think 17 is too many. What is the setup, as far as the Atomic Energy Commission is concerned, as to number, the operating board of the Atomic Energy Commission?

Dr. SCHREIBER. I do not think I should try to answer this. I am not quite sure I know your exact question. There are five commissioners.

Mr. NATCHER. That is the point I have in mind. You have five commissioners and they in turn operate and perform the duties necessary for this particular board.

Doctor, generally, how do you feel as far as research is concerned here in this country? Do we have the necessary number of properly trained individuals for our demands, at the present time?

Dr. SCHREIBER. I suppose it is true that the research activities that one can see when he is in the business will always exceed the number of people available to do the job. I think that everyone is concerned these days that we do not seem to be making research in science part of our life, sufficiently attractive, or that our training is not quite proper to keep up the rather large increase which we can see could be used in this way.

I do not pretend to any special knowledge in this. I find it, in general, hard to hire the sorts of people we want because there is a very intense competition for good people who have had adequate training; to look into the future, it looks as though this will continue. So all I can say is that I endorse the feeling that we must do a great deal to get better teaching and to encourage students to go in the field of science.

Mr. NATCHER. Do you feel that science should have a position in the Cabinet at the present time?

Dr. SCHREIBER. I do not feel competent to answer that question.

Mr. McDONOUGH. Doctor, is the ramjet the closest approach to the possibility of using nuclear propulsion power up to now?

Dr. SCHREIBER. Well, I am getting to matters of opinion now. You are contrasting this with a true nuclear rocket, I assume?

Mr. McDONOUGH. Yes.

Dr. SCHREIBER. I do not know what I can say one way or the other is any closer. Both of them have been worked out conceptually, and it appears that they can be done. It is very difficult to see what practical difficulties will arise in the course of development, and these can really throw off any prediction that is made at the present time.

Mr. McDONOUGH. You mean that we have used nuclear power for propelling a missile or rocket up to now?

Dr. SCHREIBER. No.

Mr. McDONOUGH. Are we not about ready to use the ramjet for our rocket plane? Are we not close to that or is this classified information?

Dr. SCHREIBER. This is not in my program. I do not know the time scale.

Mr. McDONOUGH. Could you give us an idea of the time schedule on the use of nuclear power or is that classified?

Dr. SCHREIBER. I would rather stay away from that, if I may.

Mr. McDONOUGH. In your description of the use of nuclear power for propelling rockets this morning, do you mean that such a vehicle, once it is propelled into outer space, would then be propelled by a nuclear engine to a planet or wherever you want it to go?

Dr. SCHREIBER. This is certainly one of the possibilities. I had rather avoided trying to speak of specific applications because there are many, many concepts, but the point I was trying to make in the

presentation this morning is that it is possible in principle to make these rather ambitious voyages starting from the earth and not use an excessive amount of propellant in order to get up to the velocities required for such exploration.

Exactly how this should be done, you can get many opinions and I think they are all simply opinions. You can have a combination of nuclear and chemical systems, you can have these appearing in various stages, you can have all sorts of auxiliary systems.

My main point this morning was to say all of these concepts are made easier if you have a basic system in which you can actually lift heavy payloads and get them up to the rather fantastic velocities which are required for lunar or space exploration.

Mr. McDONOUGH. Once the spaceship is in orbit, it should have some propelling power unit on it?

Dr. SCHREIBER. Yes.

Mr. McDONOUGH. Have we progressed to the point as to what kind of elements we would use in developing atomic power in such a spaceship?

Dr. SCHREIBER. I am getting a little on dangerous ground again, I am sorry to say.

Mr. McDONOUGH. Now, in your opinion, what is the greatest benefit in the exploration of outer space? Is it greater benefit for civilian economic uses or for military purposes?

Dr. SCHREIBER. I do not know that one can make a statement that one is above the other. It seems to me that there are both potential military and civilian applications to this and it depends a great deal upon what happens to the world in the next few years as to how these are weighted. Certainly one can see purely scientific peaceful applications which will justify quite an investigation here. I think it depends very much on the temperament of the country as to whether these peacetime benefits will provide enough impetus to carry on this program or not.

Mr. McDONOUGH. Do you see much benefit in transportation by spaceship?

Dr. SCHREIBER. Yes, it opens up this additional dimension essentially. I do not know that one can be specific and say it is economically feasible, this is one reason, or if you simply say we ought to find out more about space and that there are many reasons which make our interest valid and justifies support of the program.

I am sure you have been given all the reasons, weather forecasting, observation, and so on. I cannot contribute to this.

Mr. McDONOUGH. Except to obtain an additional point on it. The committee is interested in the variety of opinions of those who are actually engaged in the science of space technology and its future.

Mr. Natcher asked this question, and I am asking it in another way. Are we coordinating our scientific manpower and talents in the proper direction here or are we wasting some of it? Have we enough of it?

Now, those are three angles to one question.

Dr. SCHREIBER. To discuss the question of coordination, my own feeling is that when you are talking about a really exploratory investigation, a research project, as it were, that you can have too much coordination, you are looking for bright ideas, you are looking for basic research, and a certain amount of free wheeling I think is very

much justified in this case because I do not know that there is anyone who is smart enough to say: "This is the right pattern and no other will do."

As you approach a specific—I hate to use the word "requirement," it sounds too military—but as you approach a specific desire to accomplish a certain end, then I think the coordination is necessary and I think also that there has to be a coordination and exchange of information to prevent people who do not know the state of the art, let us say, from wasting a lot of time walking around in the footsteps of the people who are farthest ahead.

If you are then talking about a very specific job on a definite time scale, then I think you need a very strong management and you need to have someone, preferably an individual, who makes these decisions and has the power to make them stick.

Mr. McDONOUGH. And keep the nose to the grindstone, in other words?

Dr. SCHREIBER. Yes.

Mr. McDONOUGH. Insofar as the scientific manpower we have in this country, and the quality that it is in the upper levels, do we have a sufficient quantity of them now in the United States?

Dr. SCHREIBER. I have to define "sufficient," and this is a very difficult thing.

Mr. McDONOUGH. Well, does the education system need a stimulus to produce more?

Dr. SCHREIBER. Yes, I definitely think it does.

Mr. McDONOUGH. Then we should encourage the qualified youngsters in the lower grades to study science as a career in the United States. We need that.

Dr. SCHREIBER. I think we need that.

To digress for a moment, my wife is on the school board at Los Alamos, and she is very much aware of the fact that teachers in general are not paid as well as the professional people, that quite frequently in spite of the best efforts, it is not easy to find qualified teachers for the salaries that can be offered.

I do not think it is altogether a matter of salaries. I think it is the general education system where somehow we have not brought this up to the proper level. I simply say again that I endorse a feeling which I think is growing in this country, that our educational system must be given a stimulus. I do not mean just for the physical sciences. Let us not neglect the political sciences and the humanities.

Mr. McDONOUGH. In other words, we are not applying ourselves to an objective in our educational system as much as we should?

Dr. SCHREIBER. I think this is true.

Mr. McDONOUGH. There should be more concentration on an objective and less frills in the type of educational system we have now?

Dr. SCHREIBER. I am getting out of my area if I try to comment on that.

Mr. McDONOUGH. That is all, Mr. Chairman.

Mr. NATCHER. Mr. Fulton.

Mr. FULTON. Could you give us what you think is the dividing point or the difference in jurisdiction between the Atomic Energy Commission and a supposed national astronautical space agency? Where does the function of each of these agencies end so that there is no overlapping? How would you set that up?

Dr. SCHREIBER. This again is a policy question on which I am only giving an amateur answer.

Mr. FULTON. Rather than have an off-hand statement of it, would you put that in the record at this point as to what your personal views are, separate and apart from your Government position.

Dr. SCHREIBER. Let me speak of the agencies themselves. The Atomic Energy Commission, I feel, can best sponsor the rather specific researches which have to do with the development of systems for generating and transforming atomic energy.

If you are talking about a specific application, then probably the center of gravity falls toward the management of the overall system.

Now, if there is an agency set up that has responsibility for an overall missile system at the point where one has generated quite specific ideas and says "All right, we need this component which has certain characteristics," then certainly there has to be a shift of general responsibility into this new management system.

Mr. FULTON. Which one of the two agencies should work on nuclear-powered rockets and missiles or space vehicles?

Dr. SCHREIBER. I think it is a question of what stage of development you are talking about. I am going to avoid the question of whether it should be NASA or AEC, because I do not feel competent to comment on this. But if you set up a missile agency, then it must, I think, take over jurisdiction at the point where you have a quite specific objective.

The research, I think goes back to my previous comment, that when you are doing research and general development, perhaps it does not matter too much, you do not need a close control over what is done; in fact, it is preferable not to have too close control.

Mr. FULTON. With the Atomic Energy Commission engaged in developing, through governmental and private means, nuclear atomic powerplants, you would then distinguish, and on a particular project like a nuclear-powered rocket you would have the nuclear powerplant then executed or studied by the NASA?

Dr. SCHREIBER. Yes. This is assuming that NASA has been assigned this responsibility.

Now, exactly where one breaks over from one to the other, I think is very difficult to say. No doubt many words could go into a discussion of what makes appropriate sense.

Mr. FULTON. At the present time, you do not see overlapping causing a conflict in jurisdiction between the Atomic Energy Commission and the proposed NASA as recommended by this bill? That is the current legislation.

Dr. SCHREIBER. Again, I hate to repeat this, I do not feel really competent to judge this, but I do not see such a conflict, myself.

Mr. FULTON. What did you say, sir?

Dr. SCHREIBER. I do not personally see such a conflict, myself. It seems to me that this is not very different from the way in which, for example, the Atomic Energy Commission has worked with the Department of Defense on specific development work.

Prior to being in the Rover business, I was in the weapon engineering side of the picture, so I actually saw specific programs, in fact had responsibility for some of those where we worked with various Army, Navy, and Air Force agencies.

Mr. FULTON. On the particular application of the type of missile or vehicle, you would have that decision then made, as to the particular agency, between the Atomic Energy Commission and the NASA, that had the best facilities to do it?

Dr. SCHREIBER. Yes, think so.

Mr. FULTON. So that the policy would really be determined as much by facilities as by personnel, as we developed these two agencies?

Dr. SCHREIBER. And the need for a close association between this particular development and all of the other pieces which would have to flow into it.

Mr. FULTON. There has been testimony here of various projects which are being carried on at Los Alamos and other installations on atomic and nuclear research and development.

One witness who testified on this particular subject was Dr. Merkle of California, whom you know. I believe, too, there is a Colonel Armstrong in the room. What is his title?

Dr. SCHREIBER. Colonel Armstrong?

Mr. FULTON. Yes.

Dr. SCHREIBER. He is the deputy to General Keirn as head of the Aircraft Reactors branch in the Reactor Development Division of AEC.

Mr. FULTON. Have either of you gentlemen had any cause for concern as to the violation of any secret or classified material in the testimony so far, on atomic and nuclear programs, and especially referring to Dr. Merkle?

Dr. SCHREIBER. No. I do not know that I have seen all of the testimony, but I have not seen anything which appeared to me to violate any security.

Mr. FULTON. Does that also follow for Colonel Armstrong, who is here in the room, may I ask?

Colonel ARMSTRONG. I read Dr. Merkle's testimony, and I would say he came awfully close, but he did not violate any security.

Mr. FULTON. Would you say the same?

Dr. SCHREIBER. I would not put it as being quite as close as did Colonel Armstrong.

Mr. FULTON. But there is no violation of security?

Dr. SCHREIBER. That, I think, is quite true.

Mr. NATCHER. Mr. Ford.

Mr. FORD. No questions.

Mr. NATCHER. Mr. O'Brien.

Mr. O'BRIEN. I have one question.

This committee, to a very great extent, is treading on virgin territory. Occasionally, our questions have strayed away from the immediacy of the legislation we have before us.

Suggestion was made yesterday by Dr. Kantrowitz that we needed more of a spirit of adventure in this field. Do you believe it would be possible or desirable to work out a plan under which we could have an area for basic research, sponsored and supported by the Government, which would not be tied directly to specific projects?

Dr. SCHREIBER. I will certainly subscribe heartily to the feeling that the effort which goes into such a program must include a great deal of basic research.

As I tried to say this morning, the work which I tied to the Rover program on high temperature investigation materials actually is not

limited to the nuclear rocket propulsion application. This sort of work is needed for any of these applications, and whether administratively this sort of research should be tied into the same agency as the specific projects again I think is a rather serious policy question which depends—well, it has no simple answer. You have to ask what is the overall directive of this particular agency. Are they to do some things immediately and also plan for the future?

Are they set up for a restricted length of time to do a specific mission and so on?

I just want to add that there is a good technical reason, I believe, for trying to keep these tied together in some sort of fashion because I think that you can have very good research without having it be completely random.

Mr. O'Brien. I was not thinking completely at random, but I have been impressed by the testimony we have received as to the amount of basic research there has been in connection with these various projects. I have been impressed with the fact that the military has not strangled basic research, but the thought did occur to me that while we are working on these various projects, each with its own basic research, that it might be desirable in this agency to have an area in which scientists would work. Those scientists would have available to them the developments in these several fields and they would be permitted to conduct basic research in that spirit of adventure that Dr. Kantrowitz mentioned.

It was just a thought that occurred to me, as long as we are creating this new agency, as long as we are all anxious to move forward as rapidly as possible, that that might be possible, especially in view of the fact that so many witnesses said that the cost of basic research is not tremendous, does not involve very much hardware, and so forth.

I have one other question. So many of us have asked about this educational question. I realize it is the primary problem of another committee or committees, but I think it is part of the rounded picture.

Do you not think that our big trouble today, if we have a lack of youngsters aspiring to scientific careers, does not lie entirely with the education system or with the pay of the teachers, but the lack of desire on the part of the youngsters and their parents?

What I have in mind is this: Someone said to me during the noon recess that many of our grandfathers worked very hard as laborers, if you will. They wanted their children to become mechanics, to have a trade, and many of them did. Then those mechanics and tradesmen in turn wanted their children to be doctors or lawyers and to acquire the polish and prestige of a profession. Apparently, we have reached a certain point where we have not been advancing and it seems to me that these professional men now desire their children to be bond salesmen or insurance salesmen, because that is the shortcut to a quick buck.

Do you not believe that this breakthrough into outer space itself is going to inspire the young people and their parents to demand from the educational system the opportunities for a fuller scientific education?

Dr. Schreiber. Well, I can hope that this will happen. I suppose it will not happen without a fairly deliberate program of education. I do not mean child education but adult education essentially, to make

the general public aware of, I suppose, 2 or 3 things. One is the spirit of adventure, as you said.

Another which surprised me a little bit is that people do not believe that technical people can make a comfortable living, they have to starve in an attic, and this somehow has to be dispelled. I do not know of any single way of doing this, but I do think that a discussion of the world of tomorrow, if you will, but not expressed in science fiction language, is part of this educational program.

Mr. O'BRIEN. I think this very breakthrough is going to produce more future scientists than any of us realize, just as we had multiplicity of law schools and medical colleges as a result of the ambition of some of our fathers.

Thank you.

Mr. NATCHER. Mr. McDonough.

Mr. McDONOUGH. Pursuing the thought of Mr. O'Brien, there are fewer scientists who are sacrificing the better things of life than there are artists, sculptors, writers, and actors, are there not?

Dr. SCHREIBER. That is true.

Mr. McDONOUGH. However, those people devoted to the particular arts, artists, painters, sculptors, writers, actors, will go to great extremes to stay in their professions, in spite of the fact that they cannot eat, cannot sleep so well, or wear fancy clothes, while a scientist, if he is even an amateur or less professional than the better ones, will find a job somewhere in most cases?

Dr. SCHREIBER. In most cases, yes.

Mr. FULTON. I want to thank you for your good testimony and want to say that it has been very enlightening to us.

In conjunction with the testimony of the witness who spoke of the comments of Cicero on space, I would like to put in the record his comments from two volumes which I have obtained from the Congressional Library.

Mr. NATCHER. Without objection, it is so ordered.

(The information referred to follows:)

Danby, Wm., *The Somnium Scipionis of Cicero (and an English translation of it, with notes).*
Exeter: E. Woolmer, 1829, pp. 11, 13.

"* * * Then looking around me, I beheld a shining circle, of the most dazzling brightness, and surrounded by flames, which we, as having been taught by the Greeks, call the milky way; from whence all the other illustrious and wonderful objects were open to my view. Among these were stars which we have never seen from our earth, and of a magnitude of which we have no idea; and among these was that very small one, which, being the lowest in heaven, and nearest to our earth, shone with a borrowed light. The spheres of the stars far surpassed that of the earth in magnitude; and the earth itself appeared so small, that I was ashamed of our empire, which seemed but a point in it."

Mr. NATCHER. On behalf of our chairman, Mr. McCormack, and other members of the committee, we want to thank you for your appearance and for the fine statement you have made to the committee. You will have a chance, Doctor, to go over your testimony. Any suggestions that you have to make concerning this legislation that you did not make in your testimony before the committee, you are privileged to add. We shall appreciate any recommendations that you make.

Thank you very much, Doctor.

Dr. SCHREIBER. Thank you.

Mr. NATCHER. At this time we have with us Dr. Stanislaus Ulam, Research Advisor of the Office of the Director of the Los Alamos Scientific Laboratory of the Atomic Energy Commission.

Doctor, will you come around and have a seat? We are delighted to have you at this time. Do you have a general statement to make?

STATEMENT OF DR. STANISLAUS ULAM,[17] RESEARCH ADVISOR, OFFICE OF THE DIRECTOR, LOS ALAMOS, N. MEX., SCIENTIFIC LABORATORY, ATOMIC ENERGY COMMISSION

Dr. ULAM. No, I would like to say it is a great privilege and honor to be here and perhaps make a few remarks of a general type.

Mr. NATCHER. Go right ahead.

Dr. ULAM. It seems to me that the business of the proposed agency and the subject of discussion of this committee will concern nuclear propulsion.

Now, it is my own personal opinion that the future of space navigation and astronautics will more and more, and soon—I will go into time scales later—involve these novel matters of releasing energy, and the motors and the vehicles cruising sometimes in the near future in space will be nuclearly powered.

I say this because I noticed in previous testimony, on previous days, there was an undertone of omission of this very vital and substantial part of the program, partly because certain things cannot be said, they are classified; the technical details.

Now I will not go near those regions, but no doubt, it is not a question of conjecture nor of optimism, but one might say it is mathematically certain that it will be the nuclearly powered vehicle which will hold the stage in the near future. That is not to say, and I want to emphasize it, that one should not pursue all the presently conceived and proposed chemical ideas as much as possible. That has been worked on for a long time, they are older historically and technologically, and by all means all of the work that has been discussed in detail by various speakers should go on.

But, as I said before and I repeat it again, the question of nuclear propulsion, is not a side issue; it will be the main means in the near future to obtain these aims.

The ion propulsion and the other schemes mentioned here briefly will also play a role, perhaps later. That to me seems to be the natural order of things. The reasons are very simple.

As you have heard from General Boushey and Dr. Schreiber, the ratio of energies contained in an amount of matter, chemically, between that amount which is contained chemically and the nuclear amount, is enormous. Nuclear energy is millions of times greater. The question is how to release it without burning the whole vehicle.

Now, even the modest original proposals which, if you want schemes somewhat obvious (to everybody who realizes the potentialities of nuclear energy) when realized will be vastly better than any chemical means.

---

You have heard the technical expressions: The thing is measured in specific impulse, which simply means the velocity of the stuff you eject. The present chemical velocities correspond to specific impulses of, say, 250. The absolute theoretical limit of chemical propulsion is 400.

On the other hand, the most modest initial nuclear planning starts with 750 and goes on to numbers vastly greater than that.

Mr. McDonough. You say the absolute is 400?

Dr. Ulam. The theoretical limit of chemical reaction is 400.

Mr. McDonough. Four hundred what?

Dr. Ulam. Units of specific impulse which means, let us say, that the thing you eject will have a velocity of 4 kilometers a second.

Now, the nuclear specific impulse which is envisioned in the Rover project is 750 units. It is not the difference between 750 and 400 which you might say is hardly a ratio of 2. This ratio goes into an exponent of a number called "e" which is 2.72. It is a very important number in mathematics. It is as important as pi. It is important in logarithms.

I could give you a short lecture and explain to you what it is all about. At any rate, there is a ratio of 750 to 350 that goes into the exponent of the number "e." For example, e to the third power is about 20. That means the following thing: That if you have 3 times the specific impulse, say in nuclear propulsion, than you would have chemically, then the ratio of the final pay load to the whole initial weight of the vehicle and the fuel will be e cube times or 20 times better.

In other words, if, by any (somewhat conventional, present) means you can put a ton in a satellite orbit using a vehicle initially weighing 100 tons, you have payload to fuel ratio of 100 to 1. With nuclear propulsion you could diminish this ratio to something like 8 to 1 or less, say 4 to 1, so it would take you only 8 tons to put 1 ton, or for 100 tons initially you could have 12 tons as a final weight of the vehicle, and so on.

There is almost no limit, theoretically, to the economy in the ratio between the initial and final weight which you can achieve nuclearly.

Mr. McDonough. That you can achieve by nuclear power?

Dr. Ulam. Yes.

Mr. Fulton. To put that in more simple laymen's terms, 1 pound of nuclear substance for generating power is equal to about 2,000 tons of coal, is it not?

Dr. Ulam. Yes, something like that. It is a factor of over a million. You mentioned a factor of 4 million. Two thousand tons is 4 million pounds.

Mr. Fulton. If we had some sort of chemical that we were going to put up there in the space vehicle in order to have it ignite or explode, we would likewise have to have another chemical element with it which would about possibly double the weight, a hypergolic fuel, would we not?

Dr. Ulam. I do not quite understand the question. You want to carry the chemical fuel into the satellite?

Mr. Fulton. We have to have another fuel with it to make it explode or ignite when we are out of the air?

Mr. Ulam. It has to carry the whole thing.

Mr. FULTON. You have to really carry double in the chemical fuel when you are beyond the air, when there is not enough oxygen to ignite it, so you have to assume hypergolic or ignition-contact fuel.

Dr. ULAM. You have to eject back of the vehicle some kind of a mass. One great advantage of nuclear propulsion is that you can eject light material, like hydrogen. Now, that is a technical point which involves some little mathematics. It pays to eject light stuff.

Mr. McDONOUGH. You mean lightweight material?

Dr. ULAM. Yes.

Mr. McDONOUGH. Hydrogen, of course, would be the lightest?

Dr. ULAM. Yes. And that you can do if you use nuclear heating of the hydrogen and put it to high temperature and out it goes, and it gives a thrust to the vehicle.

Now, there are other methods and ideas for nuclear propulsion, some rather exotic but very promising, but I cannot go into details.

Mr. FELDMAN. Doctor, I do not mean to interrupt you, but what is the danger from radiation in such a program from the use of nuclear reactors for propulsion?

Dr. ULAM. You mean in case of manned or unmanned vehicles?

Mr. FELDMAN. Both.

Dr. ULAM. If you have an unmanned vehicle, there is no danger whatsoever because the damage to materials is absolutely insignificant.

Mr. FELDMAN. Would there be any pollution of the air?

Mr. ULAM. On the takeoff, you mean?

Mr. FELDMAN. Yes.

Dr. ULAM. Extremely little. The energy required to start propelling the vehicle is very, very small compared to the smallest atomic bomb that was ever shot off, extremely small. In fact, one could conceive, one has conceived manned vehicles, objects weighing many tons, propelled nuclearly and with an expenditure of fissionable material so small that there would not be, seemingly, any danger to inhabitants of the vehicle if they had some shielding.

Mr. FELDMAN. How about the manned vehicle? The same way?

Dr. ULAM. Apparently it will not be excessive. There are ways to do it.

Mr. FELDMAN. Is there any standard of measurement or any criterion or is this a problem at all in connection with the development of the nuclear submarine?

Mr. ULAM. The nuclear submarine is a heavy object which has a lot of shielding, and nuclearly propelled rockets in some years, let us say in 10 or 20 years, will be so big that the shielding will not be a problem either.

I have talked a bit too much perhaps. I merely wanted to answer questions, but I did want to make this point that nuclear propulsion is not something far away in the future or a speculative dream, but concrete things are being done now. More ambitious, but still concrete looking things are being planned after that.

Mr. FELDMAN. I did not mean to cut you off. I wanted you to continue this fact because it is very interesting.

Dr. ULAM. I am about to finish this preamble. I would like to answer questions if I may.

Mr. NATCHER. Mr. Chairman.

The CHAIRMAN. No questions.

Mr. NATCHER. Mr. O'Brien.

Mr. O'BRIEN. Doctor, as I understand your proposal, we should stamp "urgent" on this question of nuclear propulsion without in any way standing still in the meantime in the other fields, is that correct?

Dr. ULAM. Absolutely.

Mr. O'BRIEN. Whether it is this agency or whatever agency of government, they should push nuclear propulsion as rapidly as possible?

Dr. ULAM. That is my personal feeling, yes.

Mr. O'BRIEN. I have just one other question.

We have discussed from time to time the peaceful exploitation of outer space. We have heard mention of the weather and communications and also transportation. I am quite interested in that. Would you say that before outer space transportation could become really feasible, we would have to develop nuclear propulsion?

I am thinking in terms of transporting caravans of cargo, we will say, from New York to London.

Dr. ULAM. Yes, apparently if one wants very heavy satellites or floating laboratories or observatories, nuclear power is the way to do it.

Mr. O'BRIEN. And perhaps the only way, if you are going to get into caravans of vehicles traveling through the sky?

Dr. ULAM. Yes. All these things seemed like complete fantasy some years ago, let us say 15 years ago. Strangely enough, they are within reach of technological realization.

Now, you mentioned other things. The weather control first involves the ability to calculate or predict weather which we do not have yet. That hinges on other things, on theoreticians who are able to calculate such flows and the development of computing machines, and so forth. For observations of the weather pattern from the upper atmosphere, you do not need to go to the moon for that, but if you have good big satellites which act as observatories, they will enable us to understand how weather behaves now, and this is a necessary step in order, some years later, to try to influence the weather.

The question was asked this morning of General Boushey, Does it have any value or will the investment pay?

It seems to me it is obvious that the ratio is almost infinite; anyway, if it will enable us to improve and control weather, the value of it should be measured in untold billions. This will revolutionize, of course, sometime, life on this plant.

That is just one thing. Then of course, what the future holds more remotely, nobody knows, but it is an old dream of mankind, it is certainly something of tremendous scientific interest for astronomers and others, to be able to have laboratories or observatories cruising in space, or perhaps even people doing that.

Mr. FELDMAN. Would you liken that to the experience in the atomic energy field with which you were well acquainted?

Dr. ULAM. Yes.

Mr. FELDMAN. I understand the investment there has been in excess of $14 billion, but the payoff in isotopes alone has more than canceled out the investment.

Dr. ULAM. I cannot judge the costs or value. Certainly the medical value alone is very great. Much of the expense in atomic energy can

be justified on quite different grounds, namely military necessity. It is hard to measure. The peacetime benefits in time will be enormous.

Mr. FELDMAN. The reason I mentioned that is because this project will cost a great deal of money, but in return for it, there will be an enormous quid pro quo.

Dr. ULAM. Yes.

May I say the money involved in developing nuclear propulsion is of an entirely different order of magnitude than the development of atomic nuclear energy, which was much more. It would not be necessary, seemingly at least, to have any billions of dollars, but much less will suffice to develop the principles and then prove by experimentation certain ways of establishing nuclear motors. But the project will not end there. There will be other ways, already conceived and being calculated—I can not go into details—going beyond the present Rover project and all these will certainly occupy the proposed agency or should occupy it to some extent. I wanted to say that the sums necessary to develop nuclear propulsion are much smaller than the cost of atomic energy in general.

Mr. O'BRIEN. Doctor, do you think that our educational system needs a little more propulsion to produce the number of scientists we are going to need in the future?

Dr. ULAM. My own feeling is, indeed, as has been said by so many people, the times are such that it is necessary to have more scientists, not only because of external danger to the country, but the development of technology, the peaceful technology.

The Pandora's box has been opened, the whole thing is developing now at a much faster rate, and I think it will be necessary and I think it will happen that we will have more young people trained as scientists at all levels, I mean the necessary great masses of "sergeants", and more "geniuses" will come.

Mr. O'BRIEN. You think more will come into science because of the fascination of this subject?

Dr. ULAM. Yes. Science is something that many people think is worthwhile for its own sake.

Mr. O'BRIEN. Thank you very much, Doctor.

Mr. NATCHER. Doctor, have you had a chance to examine that portion of the bill before the Committee which makes provision for research into the problems of flight within and outside the earth's atmosphere?

Dr. ULAM. Yes, I read it. I canont say that I studied it in any detail. There are some cryptic things that I do not understand, but I understand the general tenor of it.

Mr. NATCHER. From your experience in connection with the Atomic Energy Commission, do you feel that such an agency should be a civilian control agency?

Mr. ULAM. My own feelings would be yes, the general direction preferably civilian, just like AEC, but in close touch with the military. It seems to me it is necessary to have the military interest constantly in mind.

Mr. NATCHER. We value your judgment and that is the reason we are asking you these questions.

This is a bill that the Committee, of course, is vitally interested in, and we want to submit to the House the proper legislation. How do

you feel about the Board provided for under this bill, Doctor, that calls for membership not to exceed 17 members?

How do you feel about this number?

Dr. ULAM. I think Dr. Schreiber said about the same thing I am going to mention. If it is an advisory board, then the number does not matter too much. If it is a governing board, it seems very large. The number 17 seems unwiedly.

By the way, I do not know what is planned, but my personal feeling would be that the AEC, just because nuclear propulsion is going to play such a role, should be on it or very strongly interacted with this agency.

Mr. NATCHER. The bill further provides for a director. In your opinion, should this director be a scientist, or what should his qualifications be? What suggestion would you have to make along that line?

Dr. ULAM. I think he should have the best scientific advice or have scientific deputies. Obviously there are questions of administration and finance on which I am not competent to say very much, but just by commonsense the man must be a "man of the world" also, in addition to all the other qualities he must possess.

Mr. NATCHER. Doctor, do you have any other suggestions to make concerning proposed legislation setting up this particular type of agency? Do you have any observations you want to make to the committee?

Mr. O'BRIEN. I am sure the doctor's testimony will stand on its own merits, its own weight in the record, but I think for those who read it, it is only fair to state—you do not have to state it, Doctor—that you probably had as much to do with the development of the hydrogen bomb as any man in the world. That is my statement. you do not have to agree or disagree with it.

Mr. NATCHER. Mr. McDonough.

Mr. McDONOUGH. You have been a scientist all your life?

Dr. ULAM. Yes.

Mr. McDONOUGH. Do you think that in the administration of this agency scientists should be unrestricted in direction on basic research; they should be free to think and act without too much direction?

Dr. ULAM. Absolutely. It is one thing to think out schemes. It is entirely different to put them into being or practice. That is where you have to have practical contributions and practical people.

Just to give an example, suppose the country were willing to spend on things of this sort—$100 million or $500 million, but not $500 billion because it is out of the question, I am just stating an extreme case—these projects have to be considered in relation to other projects going on in the country, and all the other facts of life.

Mr. McDONOUGH. A good scientist is not extravagant is he? He is conservative in his views?

Dr. ULAM. Mostly, yes.

Mr. McDONOUGH. His objective is always to find a better way to do something and to reduce the amount of effort that has been put into doing that thing in a previous manner?

Dr. ULAM. Yes, economy of thinking, certainly.

Mr. McDONOUGH. So there is not too much thinking so far as giving free thought to the scientist. He is not going to be as extravagant as some bureaucrats around here?

Dr. ULAM. Thought is always free.

Mr. McDonough. We must recognize the temperament of a scientist in his studying of the subject matter.

Dr. Ulam. Yes. There are all kinds of temperaments in science.

Mr. Natcher. Mr. Fulton.

Mr. Fulton. Doctor, we are glad to have you here. Are we in this country doing enough on the exchange of scientific knowledge on a worldwide basis?

Dr. Ulam. I do not know much about the extent in detail with which this is going on. It is nothing new. There always was some exchange of scientific knowledge.

Mr. Fulton. Do you find ready access to a sufficient volume of reference work on the subject you are working on, atomic nuclear power?

Dr. Ulam. I happen to, but that is not a good case since I have all the necessary clearance and I have complete access.

Mr. Fulton. The problem comes up on nuclear power as to the magnitude of the fuel that would be required. If you take a thousand people, that would be 150,000 pounds, 75 tons. You add another 75 tons for the vehicle. What would the weight be in ordinary terms of nuclear fuel that will be required to transport that vehicle so loaded to the moon?

Dr. Ulam. You want to have a final weight, let us say, of 200 tons, to be generous with providing some instruments.

Mr. Fulton. That would take a thousand people to the moon.

Mr. Ulam. Let us say with all the necessary books and instruments. All right, if it is the nuclear fuel itself, the uranium itself would not weigh much at all.

Mr. Fulton. How much? Ounces or pounds?

Dr. Ulam. Certainly kilograms.

Mr. Fulton. You estimate.

Dr. Ulam. To make a guess, a couple hundred kilograms.

Mr. Fulton. What part of a pound is that for us Americans?

Dr. Ulam. A kilogram is 2.2 pounds. Just multiply by two.

Mr. Fulton. You say how many kilograms?

Dr. Ulam. I am just saying, in an order of magnitude, a couple of hundred of kilograms or, say, 500 pounds or a thousand pounds. All these are small amounts.

Mr. Fulton. So it would really take a half-pound per person to go to the moon?

Dr. Ulam. No, that is the fuel element which is uranium. You have to eject from the vehicle some mass to propell. Suppose you had a lot of hydrogen stored, liquid hydrogen or some such light substance which you heat up by means of this nuclear fuel and eject it. Of that, you would have to have vastly more than kilograms.

If you want 200 tons at the end, you will have to have, say, with some very good nuclear scheme, say 600 tons or 800 tons or a thousand tons of this inert matter propelled.

You first have the energy generation, uranium or plutonium or what have you. That does not require much material, but you have then to eject some inert mass.

Mr. Fulton. Do you not simply have to eject it until you come to the edge of the earth's atmosphere and then coast to the moon?

Dr. Ulam. No. You have to achieve the so-called escape velocity, or if you are less ambitious, satellite velocity, the kind of velocity

which our Vanguard has or sputniks or Explorer. That is a very sizable velocity and to get that in your final 200 tons, you have to throw out, let us say, a thousand tons of some stuff. But that is nothing at all frightening in any way, or impossible.

Mr. FULTON. How many pounds per individual then do you visualize for both the nuclear fuel and the ejection material in order to get to the moon?

Dr. ULAM. If you want to put a pound on the moon, you have to remember that this pound of final payload has to have with it some kind of case or shielding or instrumentation. But at any rate, for the final pound of whatever you put on the moon, you have to throw out during the process of acceleration of the vehicle by nuclear means, let us say, just to make a round figure, 10 pounds.

Mr. FULTON. Now, is it not a case of ordinary chemical fuels and oxidation materials as well as the solid propellents on the third stage? It takes about a thousand pounds to get one of the Vanguard satellite pounds up?

Dr. ULAM. Yes. This ratio, as I said before, is much greater for chemical fuels because they do not have as much energy.

Mr. FULTON. So we clearly then should proceed, as has been suggested, on an urgency program to develop these nuclear fuels and propellents in order to travel far in outer space?

Dr. ULAM. Yes. Perhaps if I might qualify the word "urgency," one should do as much as is possible or feasible now without disrupting other projects.

Mr. FULTON. Yes, I would agree with that.

Dr. ULAM. In my opinion, to further this extremely important, in my view (nuclear) means of getting into space using nuclear power.

Mr. FULTON. The question comes up on the proposal for the nuclear shot in the Pacific. Do you favor this country going ahead with the shots, in view both of the danger of fallout as well as the security factors?

Dr. ULAM. That is an entirely different question, which is not related to nuclear propulsion.

Mr. FULTON. Would you say go ahead with the Pacific test just the same?

Dr. ULAM. Yes, it has been decided to.

Mr. FULTON. And there is no extreme danger either to the United States or the people of the world?

Dr. ULAM. From these shots, no. If you extrapolate over the next 5,000 years and look at cumulative effects, that is an entirely different question, but from one series of shots apparently—you see, it is not in my field; I do not know about the genetic damage.

Mr. FULTON. Yes, but you do know about the fallout?

Dr. ULAM. I know about the fallout. From one series of shots like that, there is not much danger to humanity. The danger is from the long-range extrapolation of this program.

Mr. FULTON. The question comes up on the use of velocities. Is not one of your big problems with a nuclear power to start at a velocity which will not be so large at the beginning that it destroys either the vehicle or the people?

Dr. ULAM. You mean the acceleration should not be too violent if you have people in it.

Mr. FULTON. That is right.

Dr. ULAM. Human beings can stand accelerations of the order of gravity, of which the unit is 1G, or even more, 2G, or 3G.

Mr. FULTON. The Vanguard starts at 2G's. Could a human being stand that?

Dr. ULAM. Yes. One can stand for a short time much more. You have read in the newspapers about experiments with people subject to 20G or more just once. But 2G's certainly seems harmless. In fact, in planes taking sharp banks, you get more.

Mr. FULTON. So you see no limit on acceleration on attaining speeds that are much beyond our comprehension, if we can build the proper powerplant to control it?

Dr. ULAM. No, there is a limit of acceleration that you can stand, but even with modest acceleration you can achieve in time extremely high velocity. Even with 1G which we stand here in this room all the time, with that if you let it go on for some minutes you would achieve high velocity.

Mr. FULTON. Let us talk about those extremely high velocities for a minute. In the ordinary sense of velocity as you see it, one vehicle added to another, V_1 plus V_2 is an idea of high velocity?

Dr. ULAM. Yes.

Mr. FULTON. Do you take into the equation the V_1 and V_2 or the denominator of one plus the first vehicle squared times the second vehicle squared?

Dr. ULAM. If I go 50 miles an hour in the car and something moves 10 miles inside my car, this thing moves 60 miles, you just add it. But suppose you move a couple of hundred thousand miles an hour, say 100,000 miles an hour, and in this vehicle something else moves again; well, in these velocities still much more extreme than anything considered here, very close to the velocity of light, you do not add them up any more. There is another formula.

Mr. FULTON. You say the velocities are in a field where you cannot take our ordinary velocities and just simply add them together; is that not right?

Mr. ULAM. Yes. But we do not have to worry; we are not that far yet. That will be another century when we try to approach the velocity of light in these vehicles, which indeed may come but not in this century; that I will guarantee.

Mr. FULTON. So your nuclear proposals are all within the velocities we are thinking of practically?

Mr. ULAM. Yes; this velocity is still far lower than the velocity of light, which is 300,000 kilometers per second.

Mr. FULTON. Suppose I am in a capsule going at the velocity of light at 186,300 miles a second, and throw a baseball forward 30 miles an hour. What happens?

Dr. ULAM. It still goes at the velocity of light.

Mr. FULTON. I could not throw it.

Dr. ULAM. Yes; you can.

Mr. FULTON. But it will not go anywhere?

Dr. ULAM. Yes; it will, but it will be the same as yours——

Mr. FULTON. The point I am making is this: We are coming into the problems of velocity and speeds that we cannot reason with our ordinary earthbound arithmetic figures; is that not right?

Dr. ULAM. Yes. But that is not yet in sight. Unless you want to go to other stars——

Mr. FULTON. That is what we are talking about.

Dr. ULAM. As long as we are in the solar system, people talk even of Mars or Venus or Jupiter, all these distances are relatively small compared to distances to stars.

Mr. NATCHER. Mr. Ford.

Mr. FORD. Doctor, will the apparent features of nuclear propulsion in this field have any sizable impact on the configuration of our missiles or satellites?

Dr. ULAM. In what sense?

Mr. FORD. As to size, shape, or any of the other features that are involved in the construction of a missile or satellite.

Dr. ULAM. You mean whether the missile will be like a long cylinder surmounted by a cone?

Mr. FORD. Yes.

Dr. ULAM. It is hard to say. They may be pear shaped, they may be saucers in the future. I do not think it matters.

Mr. FORD. The work we are doing on the configuration and structure and the metal, and so forth, on the vehicles themselves will not be adversely affected by the development of nuclear propulsion?

Dr. ULAM. No; not at all.

You see, once you are in free space, the shape does not matter. If there is no resistance of atmosphere, you do not need to have any special shape of the nose cone. You must have read in the newspapers that people plan to throw out a big aluminum sphere which will then cruise around the earth, unimpeded by resistance of the air, it is so high up.

Mr. FORD. So the work we are doing in all these other areas will not be adversely affected by the change in the means of propulsion. If what you are advocating comes into being, we will still be able to use it?

Dr. ULAM. Yes; it remains useful no matter what other things take place.

Mr. NATCHER. Mr. O'Brien.

Mr. O'BRIEN. This question has nothing to do with the problem at hand, but I have not been able to sleep nights because I have not had the answer yet to what happens to that baseball when it is thrown up there. Does it actually leave the thrower's hand?

Dr. ULAM. First of all, if you want to be quite technical about it, no object can quite travel with exactly light velocity. You can approach it, but you cannot travel exactly. You would need actually an infinite amount of energy. You can travel a few kilometers per second less than light, expending energy enormously but not quite infinitely.

Mr. O'BRIEN. Where is the baseball? I am still wondering. I am up there traveling at that speed and I want to throw the baseball. Will it leave my hand?

Dr. ULAM. Yes.

Mr. O'BRIEN. How far does it go?

Dr. ULAM. Just as far as if you had thrown it in the Yankee ballpark.

Mr. O'BRIEN. I have thrown it beyond the speed of light?

Dr. ULAM. No.

Mr. McDONOUGH. Instead of using a baseball, suppose you travel 186,000 miles a second.

Dr. ULAM. Yes.

Mr. McDONOUGH. That is the maximum, or we will say less than that, whatever you say, and you shoot a revolver in the forward direction in which you are traveling. Where will the bullet go?

Dr. ULAM. It will go forward. It will leave you at the same kind of speed with which the bullet leaves the revolver now. Its velocity with respect to an observer standing outside will not exceed that of the velocity of the light.

Mr. McDONOUGH. You mean it will just drop out of the gun?

Dr. ULAM. No. We are already traveling right here together with this whole room, with a velocity which is something like 30 kilometers, over 20 miles a second around the sun. The sun itself moves around the galaxy with a very great speed, several hundred kilometers a second. For all we know, our galaxy might be going thousands of kilometers a second in space with respect to some other observer. We are totally unaware of this great speed.

If you speak of velocities, we must speak with respect to an observer who is measuring this velocity.

Mr. McDONOUGH. Can you conceive of any faster speed than 186,000 miles a second?

Dr. ULAM. One can conceive it, but if you believe in the theory of relativity, which most physicists now believe, no material object can acquire and nothing can surpass the velocity of light in vacuum.

Mr. McDONOUGH. Is not the velocity of light based on the ability of man to see and observe? It is measured on the optical vision of man?

Dr. ULAM. Yes. It was done a hundred years ago by a toothed-wheel arrangement.

Mr. McDONOUGH. The speed of light cannot be measured by any other means than by the eye of man?

Dr. ULAM. Ultimately, yes; the human eye has to observe something, but it (velocity of light) has been measured very accurately by now.

Mr. McDONOUGH. So to a person who cannot see as well as another, the speed of light might be different than 186,000 miles a second?

Dr. ULAM. It is not a question of speed.

Mr. McDONOUGH. It is a question of perception?

Dr. ULAM. Yes.

Mr. FULTON. There may be stars we have never seen because they are receding from the earth at a speed greater than the speed of light?

Dr. ULAM. Yes; beyond the horizon of the universe which is very far away.

Mr. FULTON. In order that Mr. O'Brien can figure out the speed of the baseball, I think we should give him the formula as the velocity of the platform he is on, the capsule he is in, plus the velocity of the baseball, and draw a line for a fraction, and then under that put the figure 1 plus the velocity of the platform or capsule you are in squared times the velocity of the baseball squared.

Mr. O'BRIEN. I followed the gentleman very, very carefully except that I left him at the first point. I would not be in that capsule.

Mr. FULTON. Is that right, sir?

Mr. O'BRIEN. I would like to suggest, Doctor, that this problem of baseball is so far in the future that you can see no way now that it would help the Senatorial pitching staff.

Dr. ULAM. Yes. The next century.

Mr. NATCHER. Mr. Feldman, do you have any questions?

Doctor, on behalf of our chairman, Mr. McCormack, and the other members of the committee, I want to thank you for your appearance and for your fine statement. We appreciate your coming before the committee at this time.

Doctor, in examining your testimony, if you have any suggestions you would like to make or if you want to incorporate any statements which will help us with our duties, as far as this particular legislation is concerned, we will appreciate it.

Dr. ULAM. Thank you very much.

Mr. NATCHER. Thank you, Doctor.

Our next witness is Mr. Krafft Ehricke. He is chief of the preliminary designs and systems analysis of the astronautics division of Convair, San Diego, Calif.

Do you have a prepared statement you would like to make at this time, or a general statement?

STATEMENT OF KRAFFT EHRICKE, CHIEF, PRELIMINARY DESIGN AND SYSTEMS ANALYSIS, ASTRONAUTICS DIVISION, CONVAIR, SAN DIEGO, CALIF.

Mr. EHRICKE. Yes, sir. I have a prepared statement, Mr. Chairman, and with your permission I would like to read it, sir.

Mr. NATCHER. Go right ahead.

Mr. EHRICKE. Thank you, sir.

Mr. Chairman and members of the committee, when I was invited to appear before the House Select Committee on Astronautics and Space, it was suggested by your director and chief counsel that I consider primarily the subjects of rocket vehicles (including those equipped with advanced propulsion systems) and space operations.

URGENCY OF SPACE CAPABILITY

First, I would like to note that I am in full agreement with the statement of the President's Science Advisory Committee of March 26, 1958, emphasized by the President in his message to Congress of April 2, 1958, regarding the factors which urge active steps to advance space technology namely, (1) man's drive to explore the unknown, (2) the need of military vigilance in space as in all other areas accessible to potential opponents as well as to us, (3) national prestige, and (4) scientific progress. I may therefore proceed on the premise that space flight is a desirable goal and concentrate on problems and aspects of how an adequate United States space capability can be established, economically, as well as without further delay.

ADEQUACY OF SPACE CAPABILITY

With adequate space capability I mean:

(1) Scientifically: That we must stay abreast in space science—that is, not in all specific missions, but in the average.

(2) Militarily: That we must be as capable as any other nation.

(*a*) To operate weapon systems in space with missions pertaining to the earth's surface.

(*b*) To conduct earth-to-orbit and orbit-to-orbit warfare, both in the defensive and the offensive sense of the term.

With all due recognition of the legitimate needs of other important national projects, we must strive to attain leadership in the development of space flight true to the technical, scientific, and pioneering heritage of the Nation.

EMPHASIS OF CAPABILITY OVER INDIVIDUAL MISSIONS

Those of us who in the past years have urged that adequate attention be given to the prospects of instrumented and manned space flight find themselves now sometimes indirectly accused of utilizing the Russian advances to advocate a reckless plunging into space ventures in all directions without regard of cost to the Nation, military relevance, and the legitimate requirements of other fields.

This argument ignores, or fails to recognize, a fundamental fact in astronautics, which, I believe, is of importance in this hearing, namely, that there are only relatively few but broad energy plateaus as far as the performance requirements for space flight missions are concerned. The energy required is given by the ideal mission velocity which is the sum of all the velocity changes made during a given mission, plus the velocities you lose, while under power. For various missions one adds this all up and then the figures.

Figure 1 illustrates this in a schematic manner. You will notice that widely different distances are covered within the limits of one plateau, depending upon the mission. Each plateau represents conservative values; that is, you probably will need a bit less. Each plateau requires essentially one vehicle type. Therefore, by becoming capable of carrying out a mission which corresponds to a particular plateau, the resulting vehicular capability gives us the option to choose between a considerable variety of alternate missions. For instance, by attaining the capability of flying surface-to-surface from earth to moon, we have at the same time attained the capability of operating in the entire inner solar system. Every expert in the world will know this. We don't have to prove it. The engineers in Russia will know it, and if we do one thing but not the other belonging to the same plateau they will tell Khrushchev we can do it if we want to. Therefore, the emphasis is here on capability. My point is and has been in the past not to advocate that we do all the space missions that can be done, but rather that we concentrate our strength by attaining a given space capability and gradually augment it, as time progresses. The confusing variety of possible space missions becomes more simple and lucid as soon as we begin to think and plan in terms of performance plateaus and their associated capabilities, and, I might add, industrial and other requirements.

This is, of course, not the whole story of space operations, but a fundamental part thereof inasmuch as the development of space vehicle systems is not only very expensive but also very time consuming. Once a competitor is ahead of us in the development of a vehicle signifying a certain capability plateau, it takes time—more

than money—to catch up with him. Another important aspect is that of ground organizations and launching sites. Launching sites for ballistic weapon systems are extremely expensive, because they are needed in large numbers.

The numerical requirements in the case of nonmilitary—and in many cases also of military—space operations are much more modest, because there are not so many appropriately located places to launch space vehicles. In either case, however, their relative cost decreases with the number of launching which they handle. Therefore, if launching sites for space vehicles are selected judiciously, to enable one to reach as many orbits as possible from a given site, it will be feasible to reduce their cost to much lower values than those we have to accept at present for the buildup of a retaliatory ICBM and IRBM force.

A third point in regard to space operations is that, for the various missions attached to one capability plateau, the payload requirements may vary considerably, thereby suggesting offhand the need for different vehicle sizes after all. For example, a manned expedition to Mars and back which lasts hundreds of days requires more basic payload than a manned trip around the moon which lasts only a few days. However, in space flight, variations in payload weight generally affect only the number of vehicles to be launched for the mission, rather than warranting the cost of a new vehicle development.

I have given you by necessity a simplified picture. However, I want to emphasize the fact that, especially in space flight, if we have the vehicle system, representative for a given performance plateau, adequately developed, we have accomplished the biggest part of the job and can begin to utilize the capability which corresponds to this plateau.

SPACE CAPABILITY

Figure 1 distinguishes between six plateaus or steps, representing distinct space capability levels. We have at present reached the first plateau, namely, that of small instrumented satellites in the immediate vicinity of the earth (terrestrial space). Russia has, in effect, already climbed up to the second plateau, beginning with the moon probe capability, although, to my knowledge, they have not yet flown this particular mission. However, that their capability qualifies for the second plateau is evident from the orbit and the payload of Sputnik II. We would be at par with Russia if we could use our ICBM vehicles today for launching space probes into earth satellites and to the moon. The President has authorized ARPA to introduce this year our IRBM vehicles into the space research program. These vehicles can reach the moon with proper addition of stages, but their payload weight is probably smaller than the potential Russian payload for the same mission.

The exploration of the moon is of great scientific importance and of military value due to the insight we will gain into the conditions in cislunar space the observability of the earth's surface from very high altitude. Depending on what we find out about the lunar surface, there may be an element of military interest involved, although at the present time we should regard these experiments as space-scientific in nature, rather than anything else.

Astronomically, the moon experiments are the first to require a more stringent coupling between launching site and capability of reaching the target body. While, for most satellites any launching site will do, this is no longer the case to the same degree for moon flights. For one-way missions it is still possible to fire a probe to the moon along a transfer orbit whose plane is inclined to the plane of the lunar orbit. However, the accuracy requirements become more severe in this case than if the planes of the two orbits were close or would coincide. Russia is so far north that it cannot avoid using a less favorable orbit than the United States.

This fact might have to do with their apparent delay in firing a moon shot. However, I want to emphasize that this is not a compelling reason. For more sophisticated tests requiring the probe to return to earth, conditions become even worse for a country located like Russia. An inclined orbit cannot be used, in this case, unless either the probe remains always at a great distance from the moon (which is scientifically undesirable) or considerably more energy is stored in the vehicle for powered maneuvers. Likewise, the establishment of lunar satellites becomes more expensive—in terms of energy required—when approaching the moon in inclined orbits.

Conditions become really bad for a country like Russia if one considers interplanetery probes (artificial comets). At least if chemical space ships are used, it is necessary that the launching site on this spinning gyro which we call the earth must be located in the belt between the Tropic of Cancer and the Tropic of Capricorn, or much higher energy requirements must be accepted. Russia owns no territory in this belt and therefore must either launch from the southernmost region of China or from northern Indochina or from the deep south of Egypt. However, in each case it would be just south of the Tropic of Cancer; that is, in the northernmost region of this belt.

Now, the farther the launching site is away from the Equator toward the northern or southern border of the belt, the longer becomes the interval between possible launchings; namely, when this launching site crosses the ecliptic plane. Since the launching time is, in addition, fixed by a prescribed relative position of earth and target planet, it follows that two conditions must coincide timewise to permit the launching of an artificial comet. The probability of this to occur becomes the more rare the farther away the launching site is from the Equator, involving waiting times of years or even decades between firings.

Here we have a clear example of the need for international cooperation in interplanetary experiments, if reason can prevail in these matters over hostile pride. Nations in far northern and southern territories preferably rely on nations with equatorial or near equatorial territories for the operation of launching complexes. On the other hand, observatories in the far north or south are valuable tracking stations for artificial comets at certain times. I proposed last year to the International Astronautical Federation in a paper submitted about 4 months before Sputnik I:

> * * * that serious considration be given to the organization of an International Astrophysical Decade for the study of the interplanetary environment of our earth and for the preparation of manned space flight. This operation should follow the International Geophysical Year after an appropriate time

interval and when the necessary technical prerequisites are available, perhaps from 1965 to 1975.

President Eisenhower has repeatedly emphasized this country's desire to join with other nations in the peaceful exploration and utilization of space. When Russia had the sole lead in spacecraft, Mr. Khrushchev proposed a race into space. I believe the Soviets have missed a fine opportunity here of showing that they are willing to utilize new areas of human exploration for cooperation.

I think, now, that we are a spacegoing nation also, we should take a better approach and, through our civilian space agency, when it is established, invite other nations into a cooperative effort in this matter.

The third capability plateau beyond the moon shown in figure 1 involves landing on the moon, the establishment of satellites around Venus and Mars, and probing beyond these two planets into the region close to the sun (solar probe) and into the asteroid belt between Mars and Jupiter.

When the fourth plateau is climbed, man can conduct flights around the moon nonstop from the earth's surface without the aid of assembly and fueling in an intermediate satellite orbit. If starting from a satellite orbit in this plateau, he could land a party on the moon and return. This would be primarily done on the basis of chemical power. We would be principally capable of collecting enough material in an orbit, using chemical ships, to think of a round trip to Mars or to Venus (without landing) by means of chemical spacecraft. However, I do not find this prospect very attractive since it involves very long mission periods (times of absence from earth) with the accompanying psychological problems and the enormous demands on equipment endurance and reliability. This impression is augmented by the awareness that when we are ready to undertake manned interplanetary operations (which is perhaps about 10–15 years from now), we will most likely have nuclear-powered rocket engines at our disposal.

They would (step 5) permit manned flights to the moon from the earth's surface and enable us to conduct fast interplanetary reconnaissance flights to Venus and Mars. For reasons explained above, the advantage of shortening the mission period to a year or less would have a great effect on the crew. Moreover, it seems to me that flights without landing should precede those involving a descent to the planetary suface, in order to gather the necessary information for the preparation of a planetary landing.

VEHICLES AND PROPULSION SYSTEMS

The heart of the missile or space craft is its propulsion system whose power and performance decides the vehicles range and payload capacity. Presently we have two orbital vehicles in the flight stage, the Jupiter-C and the Vanguard. In addition, the American missile arsenal offers IRBM's and ICBM's for a more consequential oribital capability, and a first lunar and interplanetary instrument-carrying capability. This capability is attained by using the booster power of the Thor, the Jupiter, and the Atlas to carry upper stages into space which transfer the required terminal velocity to the payload capsule proper.

25973—58——40

Because of its enormous booster power—the largest under development in this country—the Atlas can logically carry the greatest load into space at the earliest time. With an additional high-energy stage development which altogether represents a smaller additional effort than the effort required for any other missile presently under development, the interplanetary missions mentioned in step 2 (fig. 1) can be carried out with a meaningful payload weight. Without further changes aside from those just mentioned, Atlas could boost a heavier payload weight into space inside the planet Mercury than any of the IRBM's this year will be able to carry around the moon. The simplicity and utmost emphasis on reliability designed into the missile under the leadership of the former chief engineer and now technical director of Convair-Astronautics, Mr. K. J. Bossart, has paid rich dividend in the Atlas firing program. Notwithstanding my unforgettable days with the V-2, I must say that the Atlas flight-test program, up to now, is the most remarkable event in missile development I have witnessed. The Atlas is the first missile to be tested outright with two large engines. Not a single explosion on the test stand has occurred and no principal flaw could be found. The design of the missile is sound and reliable. I am convinced that the Atlas will be ready for the national space program in the very near future without interrupting its primary development.

Among other work Convair has teamed up with Avco in an effort to establish the first steps in manned space flight as soon as possible. If we really have an early augmentation of our national space capability at heart, we will use this vehicle—and we will initiate the before-mentioned steps to increase its performance without delay—until something better is proved out.

I am saying this in order to underline the fact that we are technically not behind Russia. We are only at the moment in our hardware capability not at the same point as Russia.

Mr. McDonough. Was the Atlas designed by a proposal from Air Force to industry to built it, or did industry submit a proposal?

Mr. Ehricke. In this particular case, industry submitted a proposal on the request of the Air Force.

In 1946 the Air Force requested a number of companies to make proposals for long-range guided missiles. These missiles can be flown ballistically or, like the Snark, with an air-breathing engine or ramjet engine.

At Convair at that time the opinion was that the ICBM was on the long run, the best solution, although the toughest to begin with.

The proposal on which the Atlas design was based has come from the engineering department of Convair as such.

Mr. Ford. Are you inferring, sir, that the Atlas powerplant puts us in the same area of capability with the Soviet Union at the present time?

Mr. Ehricke. Not at the present time, because we cannot launch the Atlas with full payload yet, we are still in the test phase, but once this is done we are at par with them so far as plateau of capability is concerned.

The Chairman. How close are we to that?

Mr. Ehricke. As far as technical capability is concerned, we are one to one and a half years behind.

This is as far as space flight is concerned. The weapons system team requires more. It requires that we set up a system of logistics and supply and train troops.

Mr. McDONOUGH. How about test flight?

Mr. EHRICKE. Test flightwise, at the present time, I think we are still behind, because the Russians have launched the ICBM over the full range of 4,000 to 5,000 miles. We have not done this.

The CHAIRMAN. In other words, your testimony is that they have at least a year and a half advantage on us?

Mr. EHRICKE. I would believe they have at least a year and a half advantage.

The CHAIRMAN. Suppose they perfect the intercontinental ballistic missile where it can hit the target. They have the propulsion power now?

Mr. EHRICKE. Yes.

The CHAIRMAN. Whether it has been perfected, is the big question, is it not?

Mr. EHRICKE. Yes, but it is not the whole question.

You see, one must make a difference between the state where the missile is technically capable of doing its job and the state where the nation's defense is equipped to such an extent with the necessary organization, the setup of the bases and so on, that this particular missile represents a retaliatory or deterrent power.

Now, I do not think that the Russians have reached that stage yet with the ICBM, but neither have we and we are behind them in this respect.

The CHAIRMAN. They are a year and a half ahead of us at the present time. The production difficulties are easier to overcome than the propulsion difficulties, are they not?

Mr. EHRICKE. Yes, in general, development requires more time than production.

The CHAIRMAN. The thought enters my mind that if they perfect the ICBM before we do, and they perfect the defense against our intercontinental bombers, SAC, where do we stand?

We talk about all these formulas with Mr. Fulton. I would like a formula of my own.

Mr. FULTON. I would like to answer your question on that one.

The CHAIRMAN. I would like to get the information from anybody. That is the key to my mind at the present time.

Mr. EHRICKE. I believe, in the time between now and the time we have perfected the missile as a deterrent power, it will be very difficult, if not impossible, for them to perfect their defense against our bomber force to such an extent that our bomber force ceases to be a deterrent means.

The CHAIRMAN. I am glad to hear that.

In other words, it is not necessary or our bombers to go actually over the target.

Mr. EHRICKE. It is not necessary that they do that. We can employ other tricks.

I think at the present time we have to rely on our bomber force as a main deterrent still for a number of years. This has nothing to do with the space capability primarily. I think these two things should be set apart.

The CHAIRMAN. Is it your opinion that we will retain a retaliatory power?

Mr. EHRICKE. Yes, sir. We have it, and we will retain it. I don't think the Russians can take that away from us.

The CHAIRMAN. In the present world of today about the only level you can deal with them is under the law of self-preservation.

Mr. EHRICKE. That is true.

The CHAIRMAN. If they ever get a decided advantage over us, why, it presents very serious thought.

Mr. EHRICKE. Yes. I think this is one of the reasons why we have to go out into outer space. It is true, there are millions of things we can do on the earth, but being a leading Nation and being responsible for the defense of a way of living on a large portion of the globe, we must go as far out as anybody else does and we must be able to meet fire with fire wherever it occurs.

There is no doubt that at least the immediate vicinity of space can be made useful in a military way. We have no idea yet firmly whether the moon or the planets will ever be, I don't know.

But certainly satellites and chemisphere and ionosphere vehicles can be made useful. We have to convince ourselves in which way they can be made useful.

We have to develop the necessary technology.

Beyond that we have to go further out and find out whether anything else could possibly threaten us or not.

For instance, with respect to lunar bases my opinion is that we really do not know yet whether a lunar base will be useful or not, but we cannot afford not to find out.

The CHAIRMAN. One thing that has occurred to me during these hearings is that I am glad we have dedicated men like you before us giving us your opinion and contributing your God-given talents for mankind, our country and our way of life.

Mr. EHRICKE. Thank you.

Mr. O'BRIEN. Do I understand that you feel that SAC has really purchased for us the most valuable 18 months in our whole history? In other words, those 18 months are mighty important and they are the holding force.

Mr. EHRICKE. I am firmly convinced. They are shields behind which we have to build up the other things.

Mr. O'BRIEN. Assuming we move along with all possible speed in the other field?

Mr. EHRICKE. Yes.

Mr. FORD. Does the Atlas missile give us the ability to get a payload like Sputnik 2 into orbit?

Mr. EHRICKE. I would say yes, definitely it gives us this capability. The Atlas itself will act as a booster. You can attach small upper stages to it.

If you take existing upper stages it can already carry at least as much into an orbit as Sputnik 2 did.

If we develop a small high energy upper stage, which weighs something like 20,000 to 30,000 pounds, then we will be able to carry some 6,000 to 8,000 pounds into an orbit, which is vastly more than Sputnik 2 has done so far.

Mr. O'BRIEN. In that subsequent development, are you talking of something within a year or two, or does it coincide with the Atlas development?

Mr. EHRICKE. It does not coincide fully with the Atlas development; depending on the permission we get to go ahead with the full development it will take two or two and a half years before we will be able to launch this payload of very high capability.

I do not know whether the time permits this, Mr. Chairman, but I have a model with me which shows one particular capability of Atlas which I think is one of the primary means by which we can leap-frog possibly the Russian development.

If I may say this, there are two things which are particularly important for the establishment of an adequate space capability in my opinion. That is to get man out into space, to be able to run man controlled ships in space, and No. 2, the adequate development of a nuclear propulsion system.

If I may, I can shorten my statement a little bit and just read my primary recommendations.

Mr. NATCHER. That will be all right. You proceed as you wish.

The CHAIRMAN. Your whole statement will be put in the record. You use your own judgment.

Mr. NATCHER. You can either complete your statement, Mr. Ehricke, or put the rest of it in the record.

After the questions we would like to examine the model and have you explain it to us.

Mr. FULTON. Before we leave Mr. McCormack's question on that same point, the question comes upon the strategic use of a weapon like Atlas.

The United States, I believe, has based its security on the fact that there is no particular system on weaponry on which we place our entire reliance. Therefore, I do not put the security of the United States or the superiority of Russia, or any possible enemy, in any one class of weaponry.

As a matter of fact, unless the ICBM is supplemented by intermediate range guided ballistic missiles, the system is not complete.

Mr. EHRICKE. I agree with that.

Mr. FULTON. The time between the B-52s in the SAC Air Force and the blank in time and distance in reaching the ICBM program is to be filled by the intermediate range missile.

In the intermediate range, between the 900 and 1,500 mile range, we can bring under accurate attack between 65 and 70 percent of the industrial territories of the military installations of both China and Russia.

Under those circumstances, if we would depend on the ICBM long-range missile alone, we would be the equivalent of doing the big Bertha operation against Paris in World War I.

In the first place, it costs too much to develop that type of missile for shorter ranges.

Secondly, on the trajectory it can easily be traced.

Third, when there is a long trajectory there is more chance of interception or diversion by a nuclear shot or some other way that has not been disclosed.

Next, it is an expensive payload because it is a concentrated payload with a small dispersal range.

On the other hand, when we have the short range guided missiles, we can fire them at a predetermined point with little instrumentation and litle chance of diversion and they would arrive much more quickly than the ICBM would. So there would be very little chance of interception.

Likewise, where we might have one ICBM, we could have a broadside of 100 intermediate range guided missiles, or ballistic missiles.

So I don't feel that we should be too concerned about the fact that we are taking the time to come up with a good ICBM program and go about it in the right way when have other available means, in the Air Force, Army, Navy, and submarines, that can protect the United States and the free world. Would you agree with that?

Mr. EHRICKE. Yes, sir; I agree with that statement.

Certainly we should not rely on one weapon system alone. I was bringing the ICBM out as an example.

In my opinion one of the most important allied weapons system presently under development is the Navy Polaris concept. This whole concept is strategically very masterful and I think it is one of the best and we will have to rely very much on this one. The air-launched missile is another important approach.

As far as the IRBMs are concerned, there is, of course, this one point: that in order to reach so many targets you have to rely on overseas bases. This is one point that some people are objecting to; they want to have the capability of striking back from the United States.

Mr. FULTON. Let me answer that argument by the statement that the ICBMs operate from immovable base while the IRBMs are on movable ones and they do not particularly have to be on land.

Mr. EHRICKE. Yes. However, I would like to say there is nothing that prevents us in future developments from putting the ICBMs also on movable bases. That is entirely possible.

Mr. McDONOUGH. In your experience with the V–2, you had a large number of failures before you finally developed it?

Mr. EHRICKE. Yes.

Mr. McDONOUGH. In its ultimate stages in perfection was it any more accurate insofar as hitting the target is concerned than our IRBMs are today.

Mr. EHRICKE. I don't think it was more accurate because the final guidance system was not developed for it. It was too late. It operated with an intermediate capability kind of guidance system.

If the final guidance system had been developed it probably would have been at least as accurate as the present IRBMs, but as it was, it was not.

Mr. McDONOUGH. You were shooting a distance less than 1,000 miles?

Mr. EHRICKE. Yes, about 200 miles.

Mr. McDONOUGH. In the IRBM program we have in this country, and the number of IRBMs we have, you can hit the target easier at a short distance than you can at a long distance?

Mr. EHRICKE. Yes.

Mr. McDONOUGH. With the ICBM that Russia may attempt to shoot here, if they ever do, from their continent to our continent,

there would be a greater possibility of error in not hitting the target?

Mr. EHRICKE. Yes. That goes for ours too, incidentally. There are ways of improving this, sir, but they would be advanced techniques. You see, at the present time we are trying to perfect the weapon system to a point where we can do something with it.

In the years thereafter, it will be possible to perfect it further as to increase of accuracy, to reduce its vulnerability, also reduce its size.

There are various things that one can do.

Mr. McDONOUGH. Do we know anything about how many ICBM's they have and how long it takes to produce one?

Mr. EHRICKE. Sir, I cannot answer that because I don't have the information about the Russian's capability.

Mr. McDONOUGH. How long does it take us to produce it?

Mr. EHRICKE. I don't know whether that is an unclassified question that I can answer here at the moment.

Mr. FULTON. The defect with the ICBM is that when it passes through the atmosphere on its initial trajectory and when it reenters it has a longer trajectory in the jet airstream above the earth than a lower type intermediate missile, does it not?

Mr. EHRICKE. There is a small difference, sir, which is, however, not significant on the orbit particularly because it passes in both cases so fast.

Mr. FULTON. It would not have any effect?

Mr. EHRICKE. No, sir; it would not have any effect. The effect that wind streams have—and you have a correct point here, however, it is not connected with the jet stream; it is connected with gusts in the atmosphere—is that you have a nose very blunt, then it is being slowed down more quickly than a sharp nose, and as it is being slowed down more quickly it is more subject to slight deflections from gusts.

This goes for both IRBM and ICBM noses.

If you wish to eliminate it for both, you must go to sharper noses.

Mr. FULTON. That nose, when it is extended to quite a surface, has a sail technique, does it not?

Mr. EHRICKE. In a sense, yes.

Mr. NATCHER. Mr. Ehricke, you may proceed with your statement, or you may insert the balance in the record and hold yourself open for questions; anything you desire.

Mr. EHRICKE. Yes, sir.

However, the thrust power of the Atlas and Titan ICBM's presently under development is limited to a few hundred thousand pounds. In conducting operational and technical studies of orbital systems several years back it became clear to me that for space flight we would need vehicles of bigger size and higher thrust power, although not quite as high as some figures presented at that time.

Four years ago, in 1954, I presented a paper to the American Rocket Society and another paper to the International Astronautical Federation in which I described and recommended a 3-stage system of about 1.7 million pound booster thrust for the establishment of consequential manned satellite systems. These vehicles were designed in 2 modifications, 1 looking like a ballistic missile for cargo supply, the other for personnel transport, carrying a lift-drag reentry system to assure return of the crew. The thrust of the second stage turned out to be 346,000 pounds, a value which resembles somewhat that of our present

ICBM's with which I was not familiar at the time. It was almost hopeless in the past years to arouse interest in a booster of such thrust power, because progress in nuclear bomb development and improvement of on-board electronic equipment indicated a trend toward lower weights, thereby suggesting that the trend in future ballistic missiles would be toward smaller rather than larger boosters. I am very glad to see increasing emphasis placed on the development of a large booster engine prototype of 1 to 1.5 million pound thrust.

My recommendation from the earlier paper is unchanged and in terms of present missiles suggests that we concentrate on the development of a booster for the present ICBM's, preferably winged and recoverable, as a next step. It is true, we most likely will not require such a booster for future ballistic missiles, but it will a few years from now be regarded as indispensable for our scientific as well as defense capability in space. A 1.5 million pound booster carrying an ICBM vehicle allows man to circumnavigate the moon starting from the earth's surface and returing into an earth satellite orbit. Whether or not the need for still larger chemical engines will exist depends primarily on our nuclear propulsion systems development program. Having the 1.5 million pound motor available, we can cluster, say, two of them and use the resulting booster for transporting a nuclear upper stage beyond the denser atmosphere where the reactor can be started at moderate shielding weight requirements for the crew, because of the absence of radiation scattering produced by air molecules. I am talking here about a nuclear heating system using, for example, hydrogen as working fluid. Such a system would have enough thrust not only to accelerate the vehicle in space, but also to decelerate or accelerate it at the moon's surface, in which case the thrust must be between 16 and 20 percent of the vehicle's weight (0.16 to 0.20 g). By changing from chemical to nuclear propulsion or the upper stage at this point of the development, we jump toward a vastly more powerful system, exceeding by far any conceivable improvement resulting from further enlarging the chemical system alone. The importance of such a system lies primarily in the fact that it enables us to establish a base on the moon, if we so desire, and to supply it with a sizeable payload, about 25,000 pounds in nonstop earth-to-moon flights without intermediate fueling. Alternately, the system provides us with the capability of conducting fast reconnaissance missions to Venus and Mars, or getting one-way heavy loads, something like 30,000 pounds nonstop from the Earth to Mars. It therefore covers actually both capability plateaus 4 and 5, in figure 1.

I would like to mention one additional level which is in the more distant future. It involves the use of very low thrust propulsion systems in orbit-to-orbit (i. e., not surfacing) spacecraft. Namely, the ion system, or the plasma system, or the photon system, and I mean the actual propulsion by light pressure, not the reflection of light, not the light sail, but the photons system that produces light and propels it out. The exhaust velocity of these propulsion systems exceeds even that of the nuclear heating system by at least a factor of 10. Thereby the vehicle can carry enormous payload weights to another planet, but due to its slowness the travel time is again very long.

Primary useful for interplanetary flights are not the photon rockets, but the ion or plasma system, but they have very low thrust-to-weight ratio.

Now, you cannot fly fast from one planet to another, you fly very slowly. It takes many days, 400 days with ion, while it takes 120 days for a nuclear ship.

Consequently, for people where you want to get across space fast for various reasons, you probably prefer the fast transportation, but if you push heavy loads, these low-thrust systems will be very good.

By combining these slow heavy-payload freighters, which could be sent ahead, with the fast nuclear passenger vehicles, mentioned before, we will attain the capability of carrying the equipment required to explore the surface of our neighboring worlds Mars and perhaps Venus, and we can land; that is, not only circumnavigate them, but go down the surface.

In conclusion I would like to summarize my main points:

1. A comprehensive, consistently supported and vigorously executed national space flight program is urgently needed. Not until we have such a program will we be able to bend the curve of our rate of progress upward to the extent required to at least match the Russian rate of progress in this field.

2. I feel that President Eisenhower's recommendation regarding the National Aeronautic and Space Agency is a very good one and should be fully supported. I have two comments in this respect: (*a*) I hope that, in implementing the President's proposal, the Director of NASA will be kept out of politics as much as possible and will be given adequate power of decision as well as the right to make commitments exceeding 1 fiscal year. (*b*) The number of people in the proposed Board of Directors is quite high (17). Perhaps thought should be given to reduce it somewhat.

I would like to add another comment to it and that is that I hope this agency is cooperating to the maximum extent with Government research and development institutes, such as the Air Force at Cambridge and Redstone Arsenal and so on, the Navy facilities, as well as industry, rather than trying to duplicate things, above all, military developments.

I think this country has a most amazing stock of responsible industrial and Government-owned development agencies that any country has in this world and we should utilize them.

If we utilize this capacity to the fullest in good cooperation with other Government agencies, especially the Department of Defense, and their facilities, I think we cannot be beaten.

3. In our space flight planning we should adopt the principle of plateaus of accomplishments or levels of capability to bring the confusing variety of possible missions into perspective and avoid diffusing our efforts.

4. We need now lunar and interplanetary space research and early development of a manned space capability. This can be accomplished by using hardware presently under development to attain maximum reliability and countdown precision at the earliest time. We are doing part of it; we are putting the IRBM's into the game right now, the Jupiter and the Thor, and one way in which we can put the Atlas in I want to point out later with the model.

5. We need vigorous engineering work toward the development of a 1.5 million-pound chemical rocket engine and smaller high-energy propellent engines for high-performance upper stages. These are

strictly engineering jobs; you don't need a Nobel Prize winner to do the job. Just take our good engineers and they can do if they are allowed to go ahead.

6. We need concentrated technical and scientific efforts to have available a nuclear heated engine when we presumably may want it, which may be as early as the second half of the next decade. That is the next plateau and we must not let anybody else outjump us in this particular field because that is more dangerous than Sputnik. Nuclear energy will mean for astronautics what the combustion engine meant for the development of aeronautics.

7. We must encourage new basic and applied research in the field of energy concentration and energy conversion techniques. Then, as the result of a deliberate rather than a crash program, based on farsight rather than a craving for immediate utility, we will 10 to 15 years from now have spacecraft propulsion systems second to none.

Thank you, Mr. Chairman, for permitting me to make this statement.

Mr. NATCHER. Mr. Chairman.

The CHAIRMAN. I have no questions to ask except to say that in reading the prepared statement, sir, it is very illuminating and complete and your extemporaneous answers to the questions were very clarifying.

Mr. NATCHER. Mr. O'Brien.

Mr. O'BRIEN. Mr. Chairman, like Chairman McCormack, I think Mr. Ehricke has done a magnificent job. I was very much encouraged by your statement that if we utilize what we have we can really go places.

Do you think that we can best do that by creating, perhaps in addition to this space agency, a Secretary of Science in the President's Cabinet who could reach all those fields and who could cooperate perhaps more closely with the Atomic Energy Commission and bring all these forces into play?

Mr. EHRICKE. I think this is a good thought, sir. I do not know exactly in what way NASA would work with AEC, but somehow it is necessary for our national space capability that these two agencies work very, very closely.

Because the heart of space flight is propulsion, all of our present difficulties in navigation, accuracy requirement, stem from the fact that we don't have enough energy.

If you have energy to make corrections, you can make a mistake and it does not matter.

The better we are in the field of propulsion, the greater will be our capability.

So we must not only have wisdom in selecting the missions; we must recognize we have to get a nuclear propulsion system as soon as possible for upper stages at least.

Mr. O'BRIEN. You think the Director of the proposed agency should be as free as possible from a political atmosphere?

Mr. EHRICKE. Yes, sir. I mean this in the sense that he should be somewhat shielded by the board in ironing out the basic line of policy and interest, I mean to weigh it and balance it to other necessary national requirements.

But when he has a line, let him go ahead and do his job and do not ask him to take too many things into consideration which should be handled at the board level, not his level.

Mr. O'BRIEN. Perhaps he should be appointed for a longer term than most public officials are appointed.

Mr. EHRICKE. I think this is true because this is a technical job more than anything else, the way I see it.

Mr. O'BRIEN. It is just as important to give him continuity as it might be for a judge, for example?

Mr. EHRICKE. Yes, sir.

Mr. O'BRIEN. Thank you very much.

Mr. NATCHER. Mr. McDonough.

Mr. McDONOUGH. No questions.

I appreciate your statement very much, sir. You have given us a very practical view of the whole thing. Knowing a little of your background and the experience you have had and the fine things you have done since you have come to this country, I feel the committee is very fortunate in having you as a witness.

We appreciate the fact that we have the use of your talents in this country.

Mr. EHRICKE. I am happy to make them available to you, sir.

Mr. NATCHER. Mr. Fulton.

Mr. FULTON. The question comes up at what stages we should develop our increased thrust engines. There have been proposals here for starting off with a third of a million-pound-thrust engine and then likewise carrying on a program for a million-pound-thrust engine.

What is your approach? Would you start with a million and a half pound thrust engine, would you try it by intermediate stages, or do you think it is necessary we build up to a million and a half pound thrust engine?

Mr. EHRICKE. I believe I would like to give my answer in two phases. If we develop a 1- to 1½-million-pound-thrust engine right now, we are making a fairly big jump, although not as big a jump as from the preliminary engine to V–2 engine.

However, on the jump to the million pound engine we are going to a large combustion chamber. We do not fully understand the problem of vibration and exitation of gas layers in large engines.

We do not understand resonance conditions in such large engines.

Therefore, I believe it is desirable to carry a 300- to 400-pound thrust engine at least up to the point where we can test fire it and see whether there are any particular changes.

We can study this engine from a technical point of view while we are going ahead and doing the breadboard design for the one million pound stage.

Mr. FULTON. We could do that in 2 years while a million would take 5 to 10 years and, if that is an estimate, how long would the million and a half pound thrust engine take?

It would be some tremendously long time, would it not?

Mr. EHRICKE. No, sir; the million and a half takes about 5 years and the 300,000 to 400,000, to be available, takes about 4 years. There is approximately a difference only of about one to one and a half years.

The one and a half million pound engine can be easily throttled to be one million without loss. It would be one and the same engine actually.

Mr. FULTON. You would rather proceed on one large engine than try to have clusters of combinations of smaller engines?

Mr. EHRICKE. Yes, sir. I think if we do it we should primarily concentrate on the one to one and a half million and keep the 300,000 pound engine as a test engine and as a technical development system.

If the need arises before we have the 1½ million we can still throw it into the missile system, but I think by doing both we are delaying the big engine.

I am not sure that that is very desirable.

Mr. FULTON. We are always trying to get the definitions here because people in various parts of the country use the words with different meanings.

For example, photon means to us just the energy or velocity of light used as a propellant rather than what we would call solar power with the sail effect.

Mr. EHRICKE. Yes, sir; the photon system in its original definition is a propulsion system in which you convert. According to Einstein's equation $E=mc^2$, you convert matter into energy. You can do this far away from the sun.

That is the photon rocket.

The other one would be the light reflecting, the sort of sail type.

Mr. FULTON. And we would need approximately 50 million square feet of sail?

Mr. EHRICKE. Very large in any case. I am not sure that this would not be too big to be practical.

Mr. FULTON. Do you think the problems of mass are too much for the ion engine programs and the photon propellent programs to solve? Should we go ahead with those two programs, or are they not practical simply because of the low rate of thrust compared to the mass involved?

Mr. EHRICKE. Sir, the ion ship is definitely practical. It has between 5×10^{-5} and 10^{-4} acceleration.

This is perfectly practical. I believe 20 years or so from now we will have freight ships going, pushing heavy payloads across the solar system using this system.

The photon rocket however, as we can see at the present time, probably will not have more than 10^{-6}.

In order to illustrate what this means, let me say the following:

The photon rocket, as often quoted by Dr. Saenger in Germany, has been quite popularized as a means for travel from one stellar system to another, from one galaxy system to another, but for one thing: If you have an acceleration of 1 G, then you reach 80 percent of light velocity after 1 year's acceleration and you have realistic effects.

The time for you passed slower. If you have, however, the photon rocket, with 10^{-6}, it takes you 1 million years to reach that condition in the first place.

In order to utilize it, you have to have generations living and dying for a million years and then you have reached the stage where your descendants really have begun to age less than the others. This is the disadvantage as we see it right now.

Unless you can change that, the photon rocket will be no good because you won't outlive the rocket.

Mr. FULTON. You look for the chance, then, that the human generations will age less if these projects were carried on to the point where we got into velocities we were speaking about previously, just under the speed of light?

Mr. EHRICKE. Yes, then they would age less.

I would like to bring up one other point. We are always looking at this from the viewpoint of propulsion, but there is another much more difficult and dangerous effect involved here.

If we have the propulsion power to push something to limit of where we get relativistic effect, where you get 90 percent light velocities, or so, then you experience something that is roughly analogous or equivalent to the aerodynamic heating problem, because now when you move almost a billion feet per second, and you have, maybe, a half square mile in area of your overall system, then you are sweeping space at the rate of about 90,000 cubic miles per second.

Now, although space theoretically is empty, it is not really empty and you are hitting an awful lot of dust and corpuscles and this cosmic debris has nearly light velocity with respect to you.

In other words, they are, with respect to you, like cosmic radiation and even if you exceed half the velocity of light, the intensity of your apparent cosmic radiation due to this friction problem and heating problem goes up so tremendously that your ship after you arrive somewhere else is probably so radioactive that you don't get out of it any more.

That is the point. You have a sort of nuclear heating and you will probably need protective spheres of 10's to 100's of miles in diameter filled with hydrogen, to protect you from this cosmic debris that runs into you and makes your whole ship radioactive in no time.

That is an even tougher problem to solve really than the propulsion system.

Mr. FULTON. Have you any idea that the problem of weightlessness can be solved by magnetic means? Can we use magnetic systems to solve that problem?

Mr. EHRICKE. We could, sir. There is one disadvantage. The magnetic field energy, the magnetic attraction decreases with the cube of distance.

If you are at any particular attracting point, if you double your distance, then your attractive power goes down to one-eighth, 2 by 2 by 2.

That means you have an enormous gradient in attractive power and that may confuse your organisms very much.

I know some space medical people do not recommend this for that particular reason. It may be better if we just rotate slowly to get artificial centrifugal gravity.

Mr. FULTON. If we are out from the earth about 25,000 miles and consider ourselves in one of these ion propelled vehicles also, then if we have 75 tons that we are speaking of, which would be 150,000 pounds, actually if that is placed in the atmosphere, it would only weigh a pound or two as we would know it on the earth's surface?

Mr. EHRICKE. Yes, far out in space its weight would be reduced.

Mr. FULTON. But the question would be then, do you feel that the mass of the vehicle would prevent us from using these lower energy

systems where the thrust might be 10 pounds of thrust, for example, to about 2 or 3 pounds of weight of the vehicle? Do you think that would prevent us from using those low accelerating type systems?

Mr. EHRICKE. Sir, if I understand your question right, you suspect that the system may accelerate faster possibly if it is further out than it is near the earth?

Mr. FULTON. No, I am saying where there is very little weight clear out beyond the earth's atmosphere, then does the problem of mass, itself, regardless of weight, make impractical a system like an ion engine because it is so low in thrust, maybe a 10-pound thrust?

Mr. EHRICKE. Sir, the mass of the vehicle would prevent the conditions that far out from being significantly better than near the earth. You see, if you are in a satellite orbit falling freely about the earth, say 300 miles altitude, then you are weightless because you are falling freely.

If you apply a very small thrust force, like an ion thrust force, you begin gradually to spiral out.

Now, your thrust to weight ratio essentially remains unchanged throughout the flight unless you are using up very much fuel; but assuming you have a high specific impulse, you don't use much mass to expell.

Then your thrust to weight ratio is the same.

In this question, divide the amount of weight that you expell by one G to get the mass consumption and multiply this value by the exhaust velocity to get the thrust. Furthermore, divide the weight of the ship by G to get its mass. Then define the acceleration in amount of thrust, divided by the mass of the vehicle, and you get the acceleration in feet per second squared and not in Gs. You will then see it makes no difference in acceleration whether you are 300 miles near the earth or 20,000 miles.

The mass of the ship is the same and therefore you don't push much faster out there or actually at all.

Mr. FULTON. I am interested in hearing you say that because you have disagreed with 1 or 2 of the previous witnesses.

Will you describe for the record, or define for us, the arc plasma system of propulsion?

Mr. EHRICKE. Yes.

This is a method of concentrating a large amount of energy in a body of gas. At the present time, you use oxygen and fuel and heat the gas up to a certain degree.

Now, this goes only so far because there is only so much energy chemically stored in the fuel. If you want to do better you can, for instance, take an electric arc and now expand this arc between two electrodes and blow a gas through. Then the tremendous energy concentration from that arc goes into this gas and more energy is being stored in the gas than by combustion. You are producing extremely hot gas.

For instance, if you have hydrogen you disassociate the hydrogen and you partly ionize it. The hydrogen becomes electrically conductive and you have a plasma. Then the gas is ejected.

Mr. FULTON. Is there any reason to believe it is better to go to, for example, Mars, leaving at sunrise and Venus at sunset, or does it not make any difference on the time of Earth's revolution when you leave the atmosphere of the earth?

Mr. EHRICKE. It does not make any difference when you leave the atmosphere of the earth, as long as you are in the correct orbital plane.

However, the time does make a difference for the relative constellation of Mars and Earth. This must be right. There is only a specific time when you can launch, but this time could be morning, night, noon, anything you want.

Mr. FULTON. This is my last point. I have been a Navy Reserve lieutenant and the Navy gave a problem for promotion points that was very simple. They said, "On a plane or missile or vehicle, in space, if the thrust equals the drag and the lift equals the gravity, what is it doing?"

Mr. EHRICKE. If velocity equals drag and lift equals gravity——

Mr. FULTON. What is the plane or missile doing?

Mr. EHRICKE. It is what we call in a condition of stationary flight.

Mr. FULTON. Stationary flight or level flight?

Mr. EHRICKE. Level flight. It goes horizontally or it could climb also, but then its velocity would have to vary according to the variation of the drag.

Mr. FULTON. But it has to be in level constant flight.

Mr. EHRICKE. You would have to say it would be in level constant flight.

Mr. McDONOUGH. You say if the thrust equals the drag and the lift equals the gravity.

Mr. EHRICKE. That is right.

Mr. McDONOUGH. They are both equal?

Mr. EHRICKE. Yes.

Mr. McDONOUGH. That is inertia, is it not?

Mr. EHRICKE. If you lay out a ramjet, then you lay out a thrust for horizontal cruising flight, so that its thrust equals its drag because it maintains whatever velocity it has at that point. You have to accelerate up to a certain velocity, of course, first. Then you keep on going in a constant speed level flight, overcoming with a certain amount of thrust just exactly the amount of drag.

That is the way I understood your question.

Mr. FULTON. Is the plane at the point of stall in the climb at that position?

Mr. EHRICKE. Not necessarily. It depends on the direction of your thrust, sir.

Mr. FULTON. I want to compliment you. You are the only scientist that has answered it so far.

Mr. NATCHER. Mr. Ford?

Mr. FORD. Mr. Chairman, I think this is a very excellent presentation.

I notice at the end of the prepared text there was a biography of Mr. Ehricke. It seems to me this should be included as part of the record.

Mr. NATCHER. Without objection, it is so ordered.

(Information referred to follows:)

BIOGRAPHY OF KRAFFT A. EHRICKE

Mr. Krafft A. Ehricke is assistant to the technical director of Convair-Astronautics, a division of General Dynamics, San Diego, Calif.

He was born March 24, 1917, in Berlin, Germany. He studied aeronautical engineering at the Technical University of Berlin and received his degree as aeronautical engineer in spring 1942. He took graduate courses in atomic physics and celestial mechanics at the University of Berlin.

Beginning in 1930, he visited frequently the amateur rocket launching site in Berlin-Reinickendorf connected with the German Rocket Society and experimented with solid propellent and carbon dioxide rockets. Because private experimental work was discouraged after 1933 he concentrated on theoretical work and model configuration studies. He received a patent on a multistage rocket and propellent feed system in 1936. Subsequently he helped establish the German Society for Space Research for which he wrote a number of technical papers on rocket propulsion systems and space-flight problems.

Periods of study alternated with military service during World War II. In June 1942 he was transferred to the Peenemuende Rocket Center and participated in the development of the V-2 rocket as well as carried out advanced propulsion systems studies. Following the termination of World War II he wrote various technical papers for the American occupation authorities (FIAT) and in 1946 was contracted to join the Department of the Army as jet propulsion research engineer He worked in Fort Bliss, Tex , on ramjets and advanced rocket vehicle system studies until, in 1950, he was transferred to the Redstone Arsenal, Huntsville, Ala., where he became chief of the Gasdynamics Section.

From 1952 to 1954, he worked in the preliminary design department of Bell Aircraft on hypersonic rocket glider projects and, in fall 1954, joined Convair as design specialist on the Atlas ICBM project. When the new astronautics division of Convair was formed, he became chief of preliminary design and system analysis. He was transferred to his present position in April 1957, and heads a small group of senior engineers to concentrate entirely on advanced studies in astronautics

He is affiliated with most western rocket and space flight societies, and has published numerous papers in various countries on astronautics and space research. He is a member of the NACA Aircraft Performances Committee. Among other awards, he is recipient of the first Guenther Loeser medal of the International Astronautical Federation for the best paper presented at the sixth International Astronautical Congress in Copenhagen, 1955, and received the astronautics award of the American Rocket Society in December 1957. He is lecturer for space-flight mechanics at the San Diego State College, and presently completes a two-volume textbook on space flight for the Van Nostrand Publishing Co He became an American citizen in San Diego in October 1955.

Mr. NATCHER. Now, Mr. Ehricke, as I understand, you have a model in the next room. With your permission, we will have it brought in, and we would like to have you explain it to us.

Mr. EHRICKE. Yes, sir.

(Off the record.)

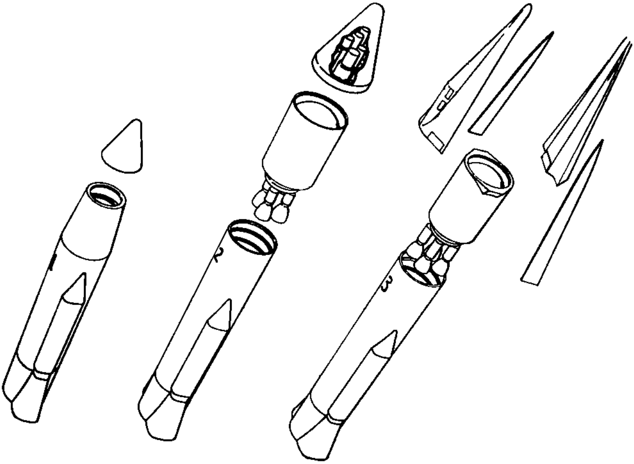
Mr. NATCHER. Mr. Ehricke, you have before us a beautiful model. We would like to have you explain the model to the committee. In making this explanation, Mr. Ehricke, keep in mind we want to get it in the record, so go into detail as much as you desire.

If any of you ladies and gentlemen sitting back in the audience want to move around and get to the side where you can see this better, we will be delighted to have you.

Mr. FULTON. Could we have Mr. Ehricke submit diagrams of the model, to be put in along with his testimony?

Mr. NATCHER. Without objection, it is so ordered.

(The diagrams follow:)



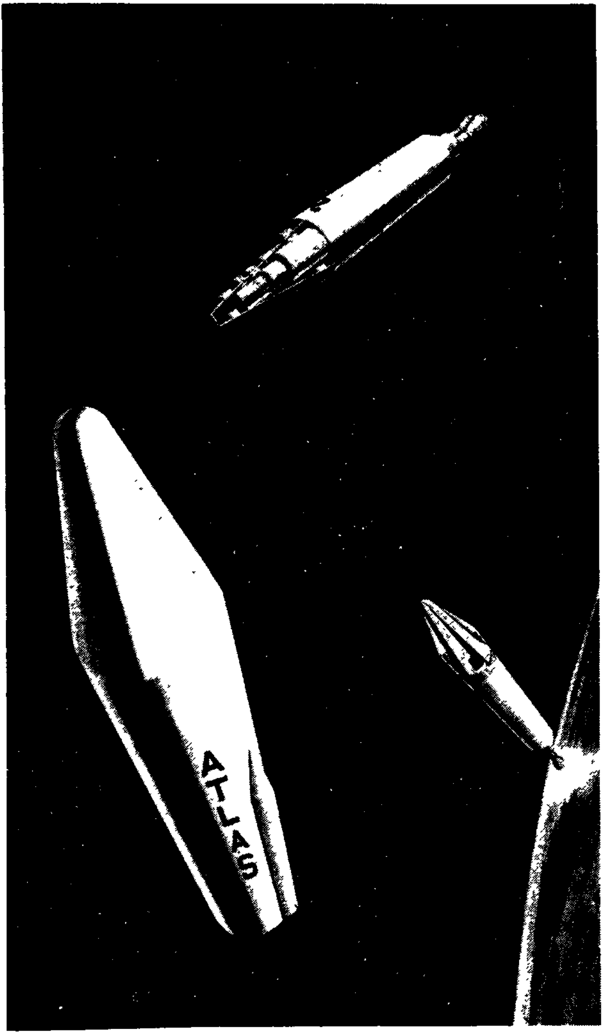
THREE ATLASES

The Atlas orbital system, a permanent manned space station proposed by Convair (Astronautics) division of General Dynamics Corp. requires three vehicles, all based on the Atlas intercontinental ballistic missile. From left, in this exploded drawing, the Atlas itself (1), which would be stripped of its weapons equipment and launched into a 400-mile orbit to become the shell of the space station; the cargo vehicle (2); and the personnel vehicle (3). Both of these latter vehicles would employ the Atlas as a booster, plus a standard second-stage rocket. The cargo vehicle would be able to carry 8,000 pounds of equipment into the space-station orbit. The personnel vehicle would mount two 2-man gliders at its tip. Near the space station, these two gliders would leave the second-stage rocket and dock at the station under power of small steering rockets. The gliders would also be used to return to the earth's surface. The station could be established within 5 years, according to its designer, Krafft Ehricke, assistant to the technical director at Convair-Astronautics, San Diego, Calif.

25973—58——41

SPACE HOUSE

The crew of the Atlas orbital system, proposed 4-man space station, would live and work in the forward tankage of an Atlas intercontinental ballistic missile launched into a 400-mile orbit to become the station's primary structure. The four-level crew quarters, as envisioned by Krafft Ehricke, assistant to the technical director of Convair (Astronautics) division of General Dynamics Corp., would provide for (from left) washroom, eating and recreation room, sleeping facilities, and control and instrumentation room. Rotating the station would give the crew an acceptable artificial gravity. Transporting men and equipment to the station would be accomplished by the Atlas booster plus a second-stage rocket, developed as part of the system. Descent from the space station would be by two-man glider.

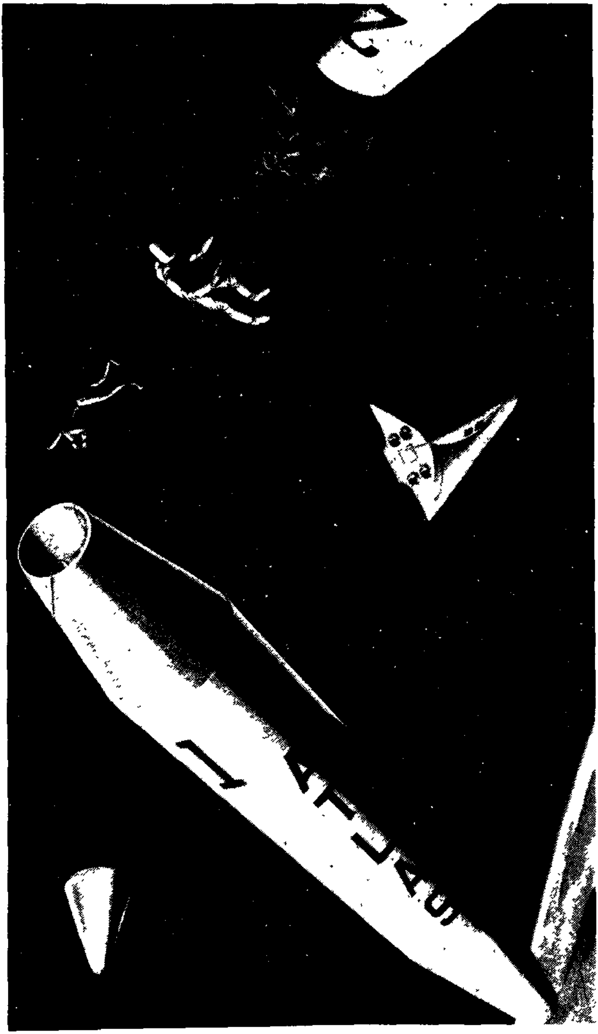


ATLAS

[First of series of three photos]

ATLAS SPACE-STATION BUILDUP

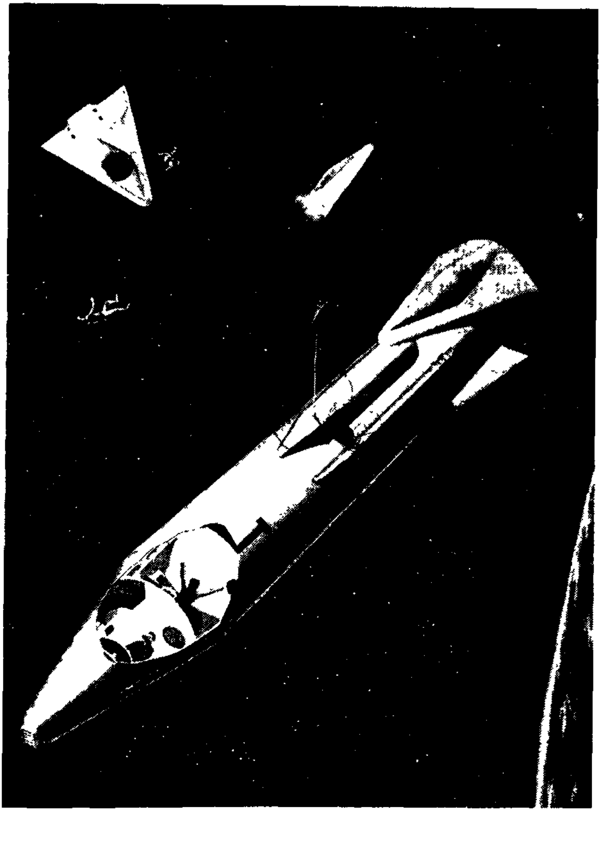
First step in establishing a permanent 4-man Atlas space station would be the placing of an Atlas intercontinental ballistic missile (1) in orbit 400 miles above the earth to serve as the shell of the station. Atlas space station could be in operation within 5 years, according to Krafft Ehricke, assistant to the technical director of Convair (Astronautics) division of General Dynamics Corp., San Diego, Calif. After Atlas shell reaches orbit, supply vehicle (2) and personnel carrier (3) would be launched and guided to the station by proportional navigation. Both supply and personnel carriers are second-stage rockets boosted into space by other Atlases. Tip of cargo carrier (2) has been cut away in drawing to show method of carrying equipment to the space station. Personnel vehicle (3) carries two two-man gliders at tip that break away when orbit is reached. Crews would dock gliders at Atlas station by small steering rockets. These two gliders would remain at the station to serve as lifeboats. Crew exchange during construction and operation of the station would be by similar second-stage gliders. Station could be completely fitted out by three cargo carriers.



[Second of series of three photos]

EQUIPPING THE ATLAS SPACE STATION

Scene depicts an intermediate stage in the establishment of an Atlas space station 400 miles above the earth. The station, proposed by Convair (Astronautics) division of General Dynamics Corp., producers of the Atlas intercontinental ballistic missile, would provide an early capability for proving long-term human existence in the environment of space. The basic structure of the station (1), the propellent tanks of the Atlas ICBM, is in orbit at left, its cap removed for access. Crewmen have arrived in a glider (center, at bottom) which has been launched into the space station orbit as part of the upper stage of a modified Atlas. A rubber nylon inflatable capsule, which will form the living quarters aboard the space station, is being removed from a cargo ship (2) at right. The completed space station would weigh about 15,000 pounds and would remain in orbit indefinitely with the help of small control rockets. The Atlas orbital system was designed by Krafft Ehricke, assistant to the technical director of Convair Astronautics, San Diego, Calif.



[Third of a series of three photos]

COMPLETED ATLAS SPACE STATION

In this artist's sketch, a new crew is arriving at the Atlas space station (1) to relieve men shown in partial cutaway of crew's quarters. Gliders bringing new crew are shown at right after separation from second-stage Atlas rocket that brought them into the space station orbit 400 miles above the earth. Cutaway section shows recreation and dining area, left, and sleeping quarters. Space suits needed for leaving the station hang on hooks against the walls. Station is entered through basket-edge manhole in side. Near it is dish antenna for communication with earth. Two personnel gliders that have been retained as lifeboats are attached to either side of the aft end of the station. Still farther aft is the auxiliary nuclear power plant, with its rectangular radiating surface to dissipate excess heat. The space station could be established within 5 years under a proposal made by Convair (Astronautics) Division of General Dynamics Corp. The station itself would be built into the empty propellant tanks of an Atlas intercontinental ballistic missile that has been stripped of its weapons equipment and launched into a 400-mile orbit. The Atlas would also be used to boost away from the earth the second-stage rockets that would carry cargo and men to the station. The proposal is the design of Krafft Ehricke, assistant to the technical director of Convair-Astronautics, San Diego, Calif., where the Atlas is in pilot production.

Mr. EHRICKE. What you see here is the layout and the design of a small experimental manned space station. It is based on the Atlas vehicle in that it represents essentially the Atlas propellant tank as such. That is the Atlas propellant tank. We have added certain equipment here and we have added other equipment there that normally is not attached to the Atlas.

The advantage of this system is that you can use the ICBM, the Atlas, and fire your basic structure, the basic tank, right out into space, and then you follow up with passenger and cargo vehicles.

I would like to show one picture that will illustrate this particular point. The orbital system as such consists of three vehicles which are shown here. The first vehicle is the Atlas itself, essentially unchanged. You take, however, all its war gear and its payload and everything out, you make it as light as possible, you have no payload. It just barely carries itself up there, but it is the only one that can do this particular thing.

Then you have another Atlas equipped with a small higher energy upper stage, the one I mentioned before in my statement. This is the same booster Atlas in the same upper stage. Now, it can carry either cargo or passengers. The passenger system here is so designed that you have two lift drag bodies, one of which seats a crew of two, and these two lift bodies are put belly-to-belly on top in the nose of the fuel system. The ship in itself, the passenger vehicle, is shown here with the two gliders, belly-to-belly, attached on top of the upper stage of the Atlas.

You see also the cargo ship, the cargo version. They are both the same. You see the basic Atlas tank. This particular version can carry about 8,000 pounds payload in this 400-mile orbit. So you go ahead and shoot the basic Atlas in the orbit and you have the empty shell which serves you as a meteor pumper and for temperature control. It is like the eggshell protecting the soft interior.

Then you send up a cargo ship and send up a passenger ship with these two twins, belly-to-belly, mounted on top. Then begins the interior decoration of the system. This is organized as follows:

On that end you have the passenger and use quarters. On that end you have the heavy equipment and supplies, and far out you have the nuclear auxiliary power system.

Now, first you bring up heavy equipment and you install it all the way back here. The reason for this being that you want the center of the mass of the system later to be as far back as possible because we anticipate that the station is going to be rotated like this in order to put the use of centrifugal force in that direction.

As you may know, the centrifugal acceleration is equal to the distance R times the square of the angle of velocity. And for a given angular velocity, therefore, it is directly proportional to the distance. The longer the distance, the less fast you have to rotate. The less fast you have to rotate, the less travel you get from the Coriolis effect. So we put all heavy equipment way down there.

After we have done this, we establish the living quarters. The living quarters come up in inflatable or come up in collapsed form. It is an inflatable rubber nylon bag that is being brought in here. This part, incidentally, can be taken off during the mounting. It is put in and then inflated and then connected.

Mr. McDonough. What is the altitude you are doing that at?

Mr. Ehricke. Four hundred miles altitude in an orbit. The work would go on as shown here; for instance, here the people are just pulling out of the supply ship, the collapsed living quarters are in a net and they pull this over to the space station and then put it in here. That is done in space itself.

Mr. McDonough. What is the temperature up there?

Mr. Ehricke. That depends on the reflectivity of your suit. You can have the temperature so that it is comfortable about sixty-five degrees Fahrenheit.

Mr. McDonough. In the suit?

Mr. Ehricke. Yes.

Mr. McDonough. The outside temperature you do not know?

Mr. Ehricke. There is no outside temperature because there is no gas, it is vacuum. The temperature depends on the amount which you absorb. It gets very cold on the shadow side of the earth, but the space suit has a heating system incorporated in it.

Mr. Ford. Are the guidance systems such that you can bring them together at such a point that a transfer or accumulation can be made?
